4.19.133 LAPACKE_cggev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggev(armpl_int_t matrix_layout, char jobvl, char jobvr,
                          armpl_int_t n, armpl_singlecomplex_t *a,
                          armpl_int_t lda, armpl_singlecomplex_t *b,
                          armpl_int_t ldb, armpl_singlecomplex_t *alpha,
                          armpl_singlecomplex_t *beta,
                          armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                          armpl_singlecomplex_t *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev*, *LAPACKE_dggev*, *LAPACKE_sggev* and *LAPACKE_zggev*. It also exists with a native Fortran interface as *cggev*.

4.19.134 LAPACKE_cggev3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggev3(armpl_int_t matrix_layout, char jobvl, char jobvr,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *b,
                           armpl_int_t ldb, armpl_singlecomplex_t *alpha,
                           armpl_singlecomplex_t *beta,
                           armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                           armpl_singlecomplex_t *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev3*, *LAPACKE_dggev3*, *LAPACKE_sggev3* and *LAPACKE_zggev3*. It also exists with a native Fortran interface as *cggev3*.

4.19.135 LAPACKE_cggev3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggev3_work(armpl_int_t matrix_layout, char jobvl,
                                char jobvr, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *alpha,
                                armpl_singlecomplex_t *beta,
                                armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                                armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev3_work*, *LAPACKE_dggev3_work*, *LAPACKE_sggev3_work* and *LAPACKE_zggev3_work*.

4.19.136 LAPACKE_cggev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggev_work(armpl_int_t matrix_layout, char jobvl,
                               char jobvr, armpl_int_t n,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               armpl_singlecomplex_t *b, armpl_int_t ldb,
                               armpl_singlecomplex_t *alpha,
                               armpl_singlecomplex_t *beta,
                               armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                               armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                               armpl_singlecomplex_t *work, armpl_int_t lwork,
                               float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev_work*, *LAPACKE_dggev_work*, *LAPACKE_sggev_work* and *LAPACKE_zggev_work*.

4.19.137 LAPACKE_cggevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggevx(armpl_int_t matrix_layout, char balanc, char jobvl,
                           char jobvr, char sense, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *alpha,
                           armpl_singlecomplex_t *beta,
                           armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                           armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t *ilo, armpl_int_t *ihi, float *lscale,
                           float *rscale, float *abnrm, float *bbnrm,
                           float *rconde, float *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggevx*, *LAPACKE_dggevx*, *LAPACKE_sggevx* and *LAPACKE_zggevx*. It also exists with a native Fortran interface as *cggevx*.

4.19.138 LAPACKE_cggevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggevx_work(armpl_int_t matrix_layout, char balanc,
                                char jobvl, char jobvr, char sense,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *alpha,
                                armpl_singlecomplex_t *beta,
                                armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                                armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                                armpl_int_t *ilo, armpl_int_t *ihi,
                                float *lscale, float *rscale, float *abnrm,
                                float *bbnrm, float *rconde, float *rcondv,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t *iwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggevx_work*, *LAPACKE_dggevx_work*, *LAPACKE_sggevx_work* and *LAPACKE_zggevx_work*.

4.19.139 LAPACKE_cggglm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggglm(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t m, armpl_int_t p,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *d, armpl_singlecomplex_t *x,
                           armpl_singlecomplex_t *y);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggglm*, *LAPACKE_dggglm*, *LAPACKE_sggglm* and *LAPACKE_zggglm*. It also exists with a native Fortran interface as *cggglm*.

4.19.140 LAPACKE_cggglm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggglm_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t m, armpl_int_t p,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *d,
                                armpl_singlecomplex_t *x,
                                armpl_singlecomplex_t *y,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggglm_work*, *LAPACKE_dggglm_work*, *LAPACKE_sggglm_work* and *LAPACKE_zggglm_work*.

4.19.141 LAPACKE_cgghd3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgghd3(armpl_int_t matrix_layout, char compq, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *q, armpl_int_t ldq,
                           armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghd3*, *LAPACKE_dgghd3*, *LAPACKE_sgghd3* and *LAPACKE_zgghd3*. It also exists with a native Fortran interface as *cgghd3*.

4.19.142 LAPACKE_cgghd3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgghd3_work(armpl_int_t matrix_layout, char compq,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, armpl_singlecomplex_t *a,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *q,
                                armpl_int_t ldq, armpl_singlecomplex_t *z,
                                armpl_int_t ldz, armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghd3_work*, *LAPACKE_dgghd3_work*, *LAPACKE_sgghd3_work* and *LAPACKE_zgghd3_work*.

4.19.143 LAPACKE_cgghrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgghrd(armpl_int_t matrix_layout, char compq, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *q, armpl_int_t ldq,
                           armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghrd*, *LAPACKE_dgghrd*, *LAPACKE_sgghrd* and *LAPACKE_zgghrd*. It also exists with a native Fortran interface as *cgghrd*.

4.19.144 LAPACKE_cgghrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgghrd_work(armpl_int_t matrix_layout, char compq,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *q,
                                armpl_int_t ldq, armpl_singlecomplex_t *z,
                                armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghrd_work*, *LAPACKE_dgghrd_work*, *LAPACKE_sgghrd_work* and *LAPACKE_zgghrd_work*.

4.19.145 LAPACKE_cgglse

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgglse(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t p,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *c, armpl_singlecomplex_t *d,
                           armpl_singlecomplex_t *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgglse*, *LAPACKE_dgglse*, *LAPACKE_sgglse* and *LAPACKE_zgglse*. It also exists with a native Fortran interface as *cgglse*.

4.19.146 LAPACKE_cgglse_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgglse_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t p,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *c,
                                armpl_singlecomplex_t *d,
                                armpl_singlecomplex_t *x,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.147 LAPACKE_cggqrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggqrf(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t m, armpl_int_t p,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *taua,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *taub);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggqrf*, *LAPACKE_dggqrf*, *LAPACKE_sggqrf* and *LAPACKE_zggqrf*. It also exists with a native Fortran interface as *cggqrf*.

4.19.148 LAPACKE_cggqrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggqrf_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t m, armpl_int_t p,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *taua,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *taub,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggqrf_work*, *LAPACKE_dggqrf_work*, *LAPACKE_sggqrf_work* and *LAPACKE_zggqrf_work*.

4.19.149 LAPACKE_cggrqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggrqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t p, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *taua,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *taub);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggrqf*, *LAPACKE_dggrqf*, *LAPACKE_sggrqf* and *LAPACKE_zggrqf*. It also exists with a native Fortran interface as *cggrqf*.

4.19.150 LAPACKE_cggrqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggrqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *taua,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *taub,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggrqf_work*, *LAPACKE_dggrqf_work*, *LAPACKE_sggrqf_work* and *LAPACKE_zggrqf_work*.

4.19.151 LAPACKE_cggsvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggsvd(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t n,
                           armpl_int_t p, armpl_int_t *k, armpl_int_t *l,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           float *alpha, float *beta,
                           armpl_singlecomplex_t *u, armpl_int_t ldu,
                           armpl_singlecomplex_t *v, armpl_int_t ldv,
                           armpl_singlecomplex_t *q, armpl_int_t ldq,
                           armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd*, *LAPACKE_dggsvd*, *LAPACKE_sggsvd* and *LAPACKE_zggsvd*.

4.19.152 LAPACKE_cggsvd3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggsvd3(armpl_int_t matrix_layout, char jobu, char jobv,
                            char jobq, armpl_int_t m, armpl_int_t n,
                            armpl_int_t p, armpl_int_t *k, armpl_int_t *l,
                            armpl_singlecomplex_t *a, armpl_int_t lda,
                            armpl_singlecomplex_t *b, armpl_int_t ldb,
                            float *alpha, float *beta,
                            armpl_singlecomplex_t *u, armpl_int_t ldu,
                            armpl_singlecomplex_t *v, armpl_int_t ldv,
                            armpl_singlecomplex_t *q, armpl_int_t ldq,
                            armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd3*, *LAPACKE_dggsvd3*, *LAPACKE_sggsvd3* and *LAPACKE_zggsvd3*. It also exists with a native Fortran interface as *cggsvd3*.

4.19.153 LAPACKE_cggsvd3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggsvd3_work(armpl_int_t matrix_layout, char jobu,
                                 char jobv, char jobq, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t p, armpl_int_t *k,
                                 armpl_int_t *l, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, armpl_singlecomplex_t *b,
                                 armpl_int_t ldb, float *alpha, float *beta,
                                 armpl_singlecomplex_t *u, armpl_int_t ldu,
                                 armpl_singlecomplex_t *v, armpl_int_t ldv,
                                 armpl_singlecomplex_t *q, armpl_int_t ldq,
                                 armpl_singlecomplex_t *work,
                                 armpl_int_t lwork, float *rwork,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd3_work*, *LAPACKE_dggsvd3_work*, *LAPACKE_sggsvd3_work* and *LAPACKE_zggsvd3_work*.

4.19.154 LAPACKE_cggsvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggsvd_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t n, armpl_int_t p, armpl_int_t *k,
                                armpl_int_t *l, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, float *alpha, float *beta,
                                armpl_singlecomplex_t *u, armpl_int_t ldu,
                                armpl_singlecomplex_t *v, armpl_int_t ldv,
                                armpl_singlecomplex_t *q, armpl_int_t ldq,
```

(continues on next page)

(continued from previous page)

```
                                armpl_singlecomplex_t *work, float *rwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd_work*, *LAPACKE_dggsvd_work*, *LAPACKE_sggsvd_work* and *LAPACKE_zggsvd_work*.

4.19.155 LAPACKE_cggsvp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggsvp(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t p,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *b,
                           armpl_int_t ldb, float tola, float tolb,
                           armpl_int_t *k, armpl_int_t *l,
                           armpl_singlecomplex_t *u, armpl_int_t ldu,
                           armpl_singlecomplex_t *v, armpl_int_t ldv,
                           armpl_singlecomplex_t *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp*, *LAPACKE_dggsvp*, *LAPACKE_sggsvp* and *LAPACKE_zggsvp*.

4.19.156 LAPACKE_cggsvp3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggsvp3(armpl_int_t matrix_layout, char jobu, char jobv,
                            char jobq, armpl_int_t m, armpl_int_t p,
                            armpl_int_t n, armpl_singlecomplex_t *a,
                            armpl_int_t lda, armpl_singlecomplex_t *b,
                            armpl_int_t ldb, float tola, float tolb,
                            armpl_int_t *k, armpl_int_t *l,
                            armpl_singlecomplex_t *u, armpl_int_t ldu,
                            armpl_singlecomplex_t *v, armpl_int_t ldv,
                            armpl_singlecomplex_t *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp3*, *LAPACKE_dggsvp3*, *LAPACKE_sggsvp3* and *LAPACKE_zggsvp3*. It also exists with a native Fortran interface as *cggsvp3*.

4.19.157 LAPACKE_cggsvp3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggsvp3_work(armpl_int_t matrix_layout, char jobu,
                                 char jobv, char jobq, armpl_int_t m,
                                 armpl_int_t p, armpl_int_t n,
                                 armpl_singlecomplex_t *a, armpl_int_t lda,
                                 armpl_singlecomplex_t *b, armpl_int_t ldb,
                                 float tola, float tolb, armpl_int_t *k,
                                 armpl_int_t *l, armpl_singlecomplex_t *u,
                                 armpl_int_t ldu, armpl_singlecomplex_t *v,
                                 armpl_int_t ldv, armpl_singlecomplex_t *q,
                                 armpl_int_t ldq, armpl_int_t *iwork,
                                 float *rwork, armpl_singlecomplex_t *tau,
                                 armpl_singlecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp3_work*, *LAPACKE_dggsvp3_work*, *LAPACKE_sggsvp3_work* and *LAPACKE_zggsvp3_work*.

4.19.158 LAPACKE_cggsvp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggsvp_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                float tola, float tolb, armpl_int_t *k,
                                armpl_int_t *l, armpl_singlecomplex_t *u,
                                armpl_int_t ldu, armpl_singlecomplex_t *v,
                                armpl_int_t ldv, armpl_singlecomplex_t *q,
                                armpl_int_t ldq, armpl_int_t *iwork,
                                float *rwork, armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp_work*, *LAPACKE_dggsvp_work*, *LAPACKE_sggsvp_work* and *LAPACKE_zggsvp_work*.

4.19.159 LAPACKE_cgtcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgtcon(char norm, armpl_int_t n,
                           const armpl_singlecomplex_t *dl,
                           const armpl_singlecomplex_t *d,
                           const armpl_singlecomplex_t *du,
                           const armpl_singlecomplex_t *du2,
                           const armpl_int_t *ipiv, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtcon*, *LAPACKE_dgtcon*, *LAPACKE_sgtcon* and *LAPACKE_zgtcon*. It also exists with a native Fortran interface as *cgtcon*.

4.19.160 LAPACKE_cgtcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgtcon_work(char norm, armpl_int_t n,
                                const armpl_singlecomplex_t *dl,
                                const armpl_singlecomplex_t *d,
                                const armpl_singlecomplex_t *du,
                                const armpl_singlecomplex_t *du2,
                                const armpl_int_t *ipiv, float anorm,
                                float *rcond, armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtcon_work*, *LAPACKE_dgtcon_work*, *LAPACKE_sgtcon_work* and *LAPACKE_zgtcon_work*.

4.19.161 LAPACKE_cgtrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgtrfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *dl,
                           const armpl_singlecomplex_t *d,
                           const armpl_singlecomplex_t *du,
                           const armpl_singlecomplex_t *dlf,
                           const armpl_singlecomplex_t *df,
                           const armpl_singlecomplex_t *duf,
                           const armpl_singlecomplex_t *du2,
                           const armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtrfs*, *LAPACKE_dgtrfs*, *LAPACKE_sgtrfs* and *LAPACKE_zgtrfs*. It also exists with a native Fortran interface as *cgtrfs*.

4.19.162 LAPACKE_cgtrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgtrfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *dl,
                                const armpl_singlecomplex_t *d,
                                const armpl_singlecomplex_t *du,
                                const armpl_singlecomplex_t *dlf,
                                const armpl_singlecomplex_t *df,
                                const armpl_singlecomplex_t *duf,
                                const armpl_singlecomplex_t *du2,
                                const armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtrfs_work*, *LAPACKE_dgtrfs_work*, *LAPACKE_sgtrfs_work* and *LAPACKE_zgtrfs_work*.

4.19.163 LAPACKE_cgtsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgtsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, armpl_singlecomplex_t *dl,
                          armpl_singlecomplex_t *d, armpl_singlecomplex_t *du,
                          armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsv*, *LAPACKE_dgtsv*, *LAPACKE_sgtsv* and *LAPACKE_zgtsv*. It also exists with a native Fortran interface as *cgtsv*.

4.19.164 LAPACKE_cgtsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgtsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, armpl_singlecomplex_t *dl,
                               armpl_singlecomplex_t *d,
                               armpl_singlecomplex_t *du,
                               armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsv_work*, *LAPACKE_dgtsv_work*, *LAPACKE_sgtsv_work* and *LAPACKE_zgtsv_work*.

4.19.165 LAPACKE_cgtsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgtsvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *dl,
                           const armpl_singlecomplex_t *d,
                           const armpl_singlecomplex_t *du,
                           armpl_singlecomplex_t *dlf,
                           armpl_singlecomplex_t *df,
                           armpl_singlecomplex_t *duf,
                           armpl_singlecomplex_t *du2, armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsvx*, *LAPACKE_dgtsvx*, *LAPACKE_sgtsvx* and *LAPACKE_zgtsvx*. It also exists with a native Fortran interface as *cgtsvx*.

4.19.166 LAPACKE_cgtsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgtsvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *dl,
                                const armpl_singlecomplex_t *d,
                                const armpl_singlecomplex_t *du,
                                armpl_singlecomplex_t *dlf,
                                armpl_singlecomplex_t *df,
                                armpl_singlecomplex_t *duf,
                                armpl_singlecomplex_t *du2, armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsvx_work*, *LAPACKE_dgtsvx_work*, *LAPACKE_sgtsvx_work* and *LAPACKE_zgtsvx_work*.

4.19.167 LAPACKE_cgttrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgttrf(armpl_int_t n, armpl_singlecomplex_t *dl,
                           armpl_singlecomplex_t *d,
                           armpl_singlecomplex_t *du,
                           armpl_singlecomplex_t *du2, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrf*, *LAPACKE_dgttrf*, *LAPACKE_sgttrf* and *LAPACKE_zgttrf*. It also exists with a native Fortran interface as *cgttrf*.

4.19.168 LAPACKE_cgttrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgttrf_work(armpl_int_t n, armpl_singlecomplex_t *dl,
                                armpl_singlecomplex_t *d,
                                armpl_singlecomplex_t *du,
                                armpl_singlecomplex_t *du2,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrf_work*, *LAPACKE_dgttrf_work*, *LAPACKE_sgttrf_work* and *LAPACKE_zgttrf_work*.

4.19.169 LAPACKE_cgttrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgttrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *dl,
                           const armpl_singlecomplex_t *d,
                           const armpl_singlecomplex_t *du,
                           const armpl_singlecomplex_t *du2,
                           const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrs*, *LAPACKE_dgttrs*, *LAPACKE_sgttrs* and *LAPACKE_zgttrs*. It also exists with a native Fortran interface as *cgttrs*.

4.19.170 LAPACKE_cgttrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgttrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *dl,
                                const armpl_singlecomplex_t *d,
                                const armpl_singlecomplex_t *du,
                                const armpl_singlecomplex_t *du2,
                                const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrs_work*, *LAPACKE_dgttrs_work*, *LAPACKE_sgttrs_work* and *LAPACKE_zgttrs_work*.

4.19.171 LAPACKE_chbev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_int_t kd,
                          armpl_singlecomplex_t *ab, armpl_int_t ldab,
                          float *w, armpl_singlecomplex_t *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.172 LAPACKE_chbev_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbev_2stage(armpl_int_t matrix_layout, char jobz,
                                 char uplo, armpl_int_t n, armpl_int_t kd,
                                 armpl_singlecomplex_t *ab, armpl_int_t ldab,
                                 float *w, armpl_singlecomplex_t *z,
                                 armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbev_2stage* and *LAPACKE_zhbev_2stage*. It also exists with a native Fortran interface as *chbev_2stage*.

4.19.173 LAPACKE_chbev_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbev_2stage_work(armpl_int_t matrix_layout, char jobz,
                                      char uplo, armpl_int_t n,
                                      armpl_int_t kd,
                                      armpl_singlecomplex_t *ab,
                                      armpl_int_t ldab, float *w,
                                      armpl_singlecomplex_t *z,
                                      armpl_int_t ldz,
                                      armpl_singlecomplex_t *work,
                                      armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbev_2stage_work* and *LAPACKE_zhbev_2stage_work*.

4.19.174 LAPACKE_chbev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, armpl_int_t kd,
                               armpl_singlecomplex_t *ab, armpl_int_t ldab,
                               float *w, armpl_singlecomplex_t *z,
                               armpl_int_t ldz, armpl_singlecomplex_t *work,
                               float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbev_work* and *LAPACKE_zhbev_work*.

4.19.175 LAPACKE_chbevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_int_t kd,
                           armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           float *w, armpl_singlecomplex_t *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbevd* and *LAPACKE_zhbevd*. It also exists with a native Fortran interface as *chbevd*.

4.19.176 LAPACKE_chbevd_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbevd_2stage(armpl_int_t matrix_layout, char jobz,
                                  char uplo, armpl_int_t n, armpl_int_t kd,
                                  armpl_singlecomplex_t *ab, armpl_int_t ldab,
                                  float *w, armpl_singlecomplex_t *z,
                                  armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.178 LAPACKE_chbevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                armpl_singlecomplex_t *ab, armpl_int_t ldab,
                                float *w, armpl_singlecomplex_t *z,
                                armpl_int_t ldz, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbevd_work* and *LAPACKE_zhbevd_work*.

4.19.179 LAPACKE_chbevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_int_t kd,
                           armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           armpl_singlecomplex_t *q, armpl_int_t ldq,
                           float vl, float vu, armpl_int_t il, armpl_int_t iu,
                           float abstol, armpl_int_t *m, float *w,
                           armpl_singlecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbevx* and *LAPACKE_zhbevx*. It also exists with a native Fortran interface as *chbevx*.

4.19.180 LAPACKE_chbevx_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbevx_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  armpl_int_t kd, armpl_singlecomplex_t *ab,
                                  armpl_int_t ldab, armpl_singlecomplex_t *q,
                                  armpl_int_t ldq, float vl, float vu,
                                  armpl_int_t il, armpl_int_t iu,
                                  float abstol, armpl_int_t *m, float *w,
                                  armpl_singlecomplex_t *z, armpl_int_t ldz,
                                  armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.181 LAPACKE_chbevx_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbevx_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       armpl_int_t kd,
                                       armpl_singlecomplex_t *ab,
                                       armpl_int_t ldab,
                                       armpl_singlecomplex_t *q,
                                       armpl_int_t ldq, float vl, float vu,
                                       armpl_int_t il, armpl_int_t iu,
                                       float abstol, armpl_int_t *m, float *w,
                                       armpl_singlecomplex_t *z,
                                       armpl_int_t ldz,
                                       armpl_singlecomplex_t *work,
                                       armpl_int_t lwork, float *rwork,
                                       armpl_int_t *iwork,
                                       armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbevx_2stage_work* and *LAPACKE_zhbevx_2stage_work*.

4.19.182 LAPACKE_chbevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_int_t kd, armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, armpl_singlecomplex_t *q,
                                armpl_int_t ldq, float vl, float vu,
                                armpl_int_t il, armpl_int_t iu, float abstol,
                                armpl_int_t *m, float *w,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work, float *rwork,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbevx_work* and *LAPACKE_zhbevx_work*.

4.19.183 LAPACKE_chbgst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbgst(armpl_int_t matrix_layout, char vect, char uplo,
                           armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                           armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           const armpl_singlecomplex_t *bb, armpl_int_t ldbb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgst* and *LAPACKE_zhbgst*. It also exists with a native Fortran interface as *chbgst*.

4.19.184 LAPACKE_chbgst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbgst_work(armpl_int_t matrix_layout, char vect,
                                char uplo, armpl_int_t n, armpl_int_t ka,
                                armpl_int_t kb, armpl_singlecomplex_t *ab,
                                armpl_int_t ldab,
                                const armpl_singlecomplex_t *bb,
                                armpl_int_t ldbb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgst_work* and *LAPACKE_zhbgst_work*.

4.19.185 LAPACKE_chbgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbgv(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                          armpl_singlecomplex_t *ab, armpl_int_t ldab,
                          armpl_singlecomplex_t *bb, armpl_int_t ldbb,
                          float *w, armpl_singlecomplex_t *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgv* and *LAPACKE_zhbgv*. It also exists with a native Fortran interface as *chbgv*.

4.19.186 LAPACKE_chbgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbgv_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, armpl_int_t ka,
                               armpl_int_t kb, armpl_singlecomplex_t *ab,
                               armpl_int_t ldab, armpl_singlecomplex_t *bb,
                               armpl_int_t ldbb, float *w,
                               armpl_singlecomplex_t *z, armpl_int_t ldz,
                               armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgv_work* and *LAPACKE_zhbgv_work*.

4.19.187 LAPACKE_chbgvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbgvd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                           armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           armpl_singlecomplex_t *bb, armpl_int_t ldbb,
                           float *w, armpl_singlecomplex_t *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgvd* and *LAPACKE_zhbgvd*. It also exists with a native Fortran interface as *chbgvd*.

4.19.188 LAPACKE_chbgvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbgvd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, armpl_int_t ka,
                                armpl_int_t kb, armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, armpl_singlecomplex_t *bb,
                                armpl_int_t ldbb, float *w,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgvd_work* and *LAPACKE_zhbgvd_work*.

4.19.189 LAPACKE_chbgvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbgvx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_int_t ka,
                           armpl_int_t kb, armpl_singlecomplex_t *ab,
                           armpl_int_t ldab, armpl_singlecomplex_t *bb,
                           armpl_int_t ldbb, armpl_singlecomplex_t *q,
                           armpl_int_t ldq, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t *m, float *w, armpl_singlecomplex_t *z,
                                armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgvx* and *LAPACKE_zhbgvx*. It also exists with a native Fortran interface as *chbgvx*.

4.19.190 LAPACKE_chbgvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbgvx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_int_t ka, armpl_int_t kb,
                                armpl_singlecomplex_t *ab, armpl_int_t ldab,
                                armpl_singlecomplex_t *bb, armpl_int_t ldbb,
                                armpl_singlecomplex_t *q, armpl_int_t ldq,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, float abstol, armpl_int_t *m,
                                float *w, armpl_singlecomplex_t *z,
                                armpl_int_t ldz, armpl_singlecomplex_t *work,
                                float *rwork, armpl_int_t *iwork,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgvx_work* and *LAPACKE_zhbgvx_work*.

4.19.191 LAPACKE_chbtrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbtrd(armpl_int_t matrix_layout, char vect, char uplo,
                           armpl_int_t n, armpl_int_t kd,
                           armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           float *d, float *e, armpl_singlecomplex_t *q,
                           armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbtrd* and *LAPACKE_zhbtrd*. It also exists with a native Fortran interface as *chbtrd*.

4.19.192 LAPACKE_chbtrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chbtrd_work(armpl_int_t matrix_layout, char vect,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                armpl_singlecomplex_t *ab, armpl_int_t ldab,
                                float *d, float *e, armpl_singlecomplex_t *q,
                                armpl_int_t ldq,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbtrd_work* and *LAPACKE_zhbtrd_work*.

4.19.193 LAPACKE_checon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_checon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, const armpl_int_t *ipiv,
                           float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_checon* and *LAPACKE_zhecon*. It also exists with a native Fortran interface as *checon*.

4.19.194 LAPACKE_checon_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_checon_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, const armpl_singlecomplex_t *a,
                             armpl_int_t lda, const armpl_singlecomplex_t *e,
                             const armpl_int_t *ipiv, float anorm,
                             float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_checon_3* and *LAPACKE_zhecon_3*. It also exists with a native Fortran interface as *checon_3*.

4.19.195 LAPACKE_checon_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_checon_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n,
                                  const armpl_singlecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_singlecomplex_t *e,
                                  const armpl_int_t *ipiv, float anorm,
                                  float *rcond, armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_checon_3_work* and *LAPACKE_zhecon_3_work*.

4.19.196 LAPACKE_checon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_checon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                float anorm, float *rcond,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_checon_work* and *LAPACKE_zhecon_work*.

4.19.197 LAPACKE_cheequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheequb(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, const armpl_singlecomplex_t *a,
                            armpl_int_t lda, float *s, float *scond,
                            float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheequb* and *LAPACKE_zheequb*. It also exists with a native Fortran interface as *cheequb*.

4.19.198 LAPACKE_cheequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheequb_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n,
                                 const armpl_singlecomplex_t *a,
                                 armpl_int_t lda, float *s, float *scond,
                                 float *amax, armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheequb_work* and *LAPACKE_zheequb_work*.

4.19.199 LAPACKE_cheev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_singlecomplex_t *a,
                          armpl_int_t lda, float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheev* and *LAPACKE_zheev*. It also exists with a native Fortran interface as *cheev*.

4.19.200 LAPACKE_cheev_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheev_2stage(armpl_int_t matrix_layout, char jobz,
                                 char uplo, armpl_int_t n,
                                 armpl_singlecomplex_t *a, armpl_int_t lda,
                                 float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheev_2stage* and *LAPACKE_zheev_2stage*. It also exists with a native Fortran interface as *cheev_2stage*.

4.19.201 LAPACKE_cheev_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheev_2stage_work(armpl_int_t matrix_layout, char jobz,
                                      char uplo, armpl_int_t n,
                                      armpl_singlecomplex_t *a,
                                      armpl_int_t lda, float *w,
                                      armpl_singlecomplex_t *work,
                                      armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheev_2stage_work* and *LAPACKE_zheev_2stage_work*.

4.19.202 LAPACKE_cheev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               float *w, armpl_singlecomplex_t *work,
                               armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheev_work* and *LAPACKE_zheev_work*.

4.19.203 LAPACKE_cheevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevd* and *LAPACKE_zheevd*. It also exists with a native Fortran interface as *cheevd*.

4.19.204 LAPACKE_cheevd_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevd_2stage(armpl_int_t matrix_layout, char jobz,
                                  char uplo, armpl_int_t n,
                                  armpl_singlecomplex_t *a, armpl_int_t lda,
                                  float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevd_2stage* and *LAPACKE_zheevd_2stage*. It also exists with a native Fortran interface as *cheevd_2stage*.

4.19.205 LAPACKE_cheevd_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevd_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char uplo, armpl_int_t n,
                                       armpl_singlecomplex_t *a,
                                       armpl_int_t lda, float *w,
                                       armpl_singlecomplex_t *work,
                                       armpl_int_t lwork, float *rwork,
                                       armpl_int_t lrwork, armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevd_2stage_work* and *LAPACKE_zheevd_2stage_work*.

4.19.206 LAPACKE_cheevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                float *w, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevd_work* and *LAPACKE_zheevd_work*.

4.19.207 LAPACKE_cheevr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevr(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, armpl_singlecomplex_t *z,
                           armpl_int_t ldz, armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevr* and *LAPACKE_zheevr*. It also exists with a native Fortran interface as *cheevr*.

4.19.208 LAPACKE_cheevr_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevr_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  armpl_singlecomplex_t *a, armpl_int_t lda,
                                  float vl, float vu, armpl_int_t il,
                                  armpl_int_t iu, float abstol,
                                  armpl_int_t *m, float *w,
                                  armpl_singlecomplex_t *z, armpl_int_t ldz,
                                  armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevr_2stage* and *LAPACKE_zheevr_2stage*. It also exists with a native Fortran interface as *cheevr_2stage*.

4.19.209 LAPACKE_cheevr_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevr_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       armpl_singlecomplex_t *a,
                                       armpl_int_t lda, float vl, float vu,
                                       armpl_int_t il, armpl_int_t iu,
                                       float abstol, armpl_int_t *m, float *w,
                                       armpl_singlecomplex_t *z,
                                       armpl_int_t ldz, armpl_int_t *isuppz,
                                       armpl_singlecomplex_t *work,
                                       armpl_int_t lwork, float *rwork,
                                       armpl_int_t lrwork, armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

                                    float *w, armpl_singlecomplex_t *z,
                                    armpl_int_t ldz, armpl_int_t *isuppz,
                                    armpl_singlecomplex_t *work,
                                    armpl_int_t lwork, float *rwork,
                                    armpl_int_t lrwork, armpl_int_t *iwork,
                                    armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevr_work* and *LAPACKE_zheevr_work*.

4.19.211 LAPACKE_cheevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, armpl_singlecomplex_t *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevx* and *LAPACKE_zheevx*. It also exists with a native Fortran interface as *cheevx*.

4.19.212 LAPACKE_cheevx_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevx_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  armpl_singlecomplex_t *a, armpl_int_t lda,
                                  float vl, float vu, armpl_int_t il,
                                  armpl_int_t iu, float abstol,
                                  armpl_int_t *m, float *w,
                                  armpl_singlecomplex_t *z, armpl_int_t ldz,
                                  armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevx_2stage* and *LAPACKE_zheevx_2stage*. It also exists with a native Fortran interface as *cheevx_2stage*.

4.19.213 LAPACKE_cheevx_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevx_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       armpl_singlecomplex_t *a,
                                       armpl_int_t lda, float vl, float vu,
                                       armpl_int_t il, armpl_int_t iu,
                                       float abstol, armpl_int_t *m, float *w,
                                       armpl_singlecomplex_t *z,
                                       armpl_int_t ldz,
                                       armpl_singlecomplex_t *work,
                                       armpl_int_t lwork, float *rwork,
                                       armpl_int_t *iwork,
                                       armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevx_2stage_work* and *LAPACKE_zheevx_2stage_work*.

4.19.214 LAPACKE_cheevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, float abstol, armpl_int_t *m,
                                float *w, armpl_singlecomplex_t *z,
                                armpl_int_t ldz, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevx_work* and *LAPACKE_zheevx_work*.

4.19.215 LAPACKE_chegst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegst(armpl_int_t matrix_layout, armpl_int_t itype,
                           char uplo, armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, const armpl_singlecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegst* and *LAPACKE_zhegst*. It also exists with a native Fortran interface as *chegst*.

4.19.216 LAPACKE_chegst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegst_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegst_work* and *LAPACKE_zhegst_work*.

4.19.217 LAPACKE_chegv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegv(armpl_int_t matrix_layout, armpl_int_t itype,
                          char jobz, char uplo, armpl_int_t n,
                          armpl_singlecomplex_t *a, armpl_int_t lda,
                          armpl_singlecomplex_t *b, armpl_int_t ldb,
                          float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegv* and *LAPACKE_zhegv*. It also exists with a native Fortran interface as *chegv*.

4.19.218 LAPACKE_chegv_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegv_2stage(armpl_int_t matrix_layout, armpl_int_t itype,
                                 char jobz, char uplo, armpl_int_t n,
                                 armpl_singlecomplex_t *a, armpl_int_t lda,
                                 armpl_singlecomplex_t *b, armpl_int_t ldb,
                                 float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegv_2stage* and *LAPACKE_zhegv_2stage*. It also exists with a native Fortran interface as *chegv_2stage*.

4.19.219 LAPACKE_chegv_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegv_2stage_work(armpl_int_t matrix_layout,
                                      armpl_int_t itype, char jobz, char uplo,
                                      armpl_int_t n, armpl_singlecomplex_t *a,
                                      armpl_int_t lda,
```

(continues on next page)

(continued from previous page)

```
                                    armpl_singlecomplex_t *b,
                                    armpl_int_t ldb, float *w,
                                    armpl_singlecomplex_t *work,
                                    armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegv_2stage_work* and *LAPACKE_zhegv_2stage_work*.

4.19.220 LAPACKE_chegv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegv_work(armpl_int_t matrix_layout, armpl_int_t itype,
                               char jobz, char uplo, armpl_int_t n,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               armpl_singlecomplex_t *b, armpl_int_t ldb,
                               float *w, armpl_singlecomplex_t *work,
                               armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegv_work* and *LAPACKE_zhegv_work*.

4.19.221 LAPACKE_chegvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegvd(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char uplo, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegvd* and *LAPACKE_zhegvd*. It also exists with a native Fortran interface as *chegvd*.

4.19.222 LAPACKE_chegvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegvd_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                float *w, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegvd_work* and *LAPACKE_zhegvd_work*.

4.19.223 LAPACKE_chegvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegvx(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char range, char uplo, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           float vl, float vu, armpl_int_t il, armpl_int_t iu,
                           float abstol, armpl_int_t *m, float *w,
                           armpl_singlecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegvx* and *LAPACKE_zhegvx*. It also exists with a native Fortran interface as *chegvx*.

4.19.224 LAPACKE_chegvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chegvx_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char range, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, float vl, float vu,
                                armpl_int_t il, armpl_int_t iu, float abstol,
                                armpl_int_t *m, float *w,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegvx_work* and *LAPACKE_zhegvx_work*.

4.19.225 LAPACKE_cherfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cherfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *af, armpl_int_t ldaf,
                           const armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cherfs* and *LAPACKE_zherfs*. It also exists with a native Fortran interface as *cherfs*.

4.19.226 LAPACKE_cherfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cherfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
```

(continues on next page)

(continued from previous page)

```
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *af,
                                armpl_int_t ldaf, const armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cherfs_work* and *LAPACKE_zherfs_work*.

4.19.227 LAPACKE_cherfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cherfsx(armpl_int_t matrix_layout, char uplo, char equed,
                            armpl_int_t n, armpl_int_t nrhs,
                            const armpl_singlecomplex_t *a, armpl_int_t lda,
                            const armpl_singlecomplex_t *af, armpl_int_t ldaf,
                            const armpl_int_t *ipiv, const float *s,
                            const armpl_singlecomplex_t *b, armpl_int_t ldb,
                            armpl_singlecomplex_t *x, armpl_int_t ldx,
                            float *rcond, float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cherfsx* and *LAPACKE_zherfsx*. It also exists with a native Fortran interface as *cherfsx*.

4.19.228 LAPACKE_cherfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cherfsx_work(armpl_int_t matrix_layout, char uplo,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const armpl_singlecomplex_t *a,
                                 armpl_int_t lda,
                                 const armpl_singlecomplex_t *af,
                                 armpl_int_t ldaf, const armpl_int_t *ipiv,
                                 const float *s,
                                 const armpl_singlecomplex_t *b,
                                 armpl_int_t ldb, armpl_singlecomplex_t *x,
                                 armpl_int_t ldx, float *rcond, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, armpl_singlecomplex_t *work,
                                 float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cherfsx_work* and *LAPACKE_zherfsx_work*.

4.19.229 LAPACKE_chesv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_singlecomplex_t *a,
                          armpl_int_t lda, armpl_int_t *ipiv,
                          armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv* and *LAPACKE_zhesv*. It also exists with a native Fortran interface as *chesv*.

4.19.230 LAPACKE_chesv_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesv_aa(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             armpl_singlecomplex_t *a, armpl_int_t lda,
                             armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                             armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_aa* and *LAPACKE_zhesv_aa*. It also exists with a native Fortran interface as *chesv_aa*.

4.19.231 LAPACKE_chesv_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesv_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs,
                                    armpl_singlecomplex_t *a, armpl_int_t lda,
                                    armpl_singlecomplex_t *tb,
```

(continues on next page)

(continued from previous page)

```
                                    armpl_int_t ltb, armpl_int_t *ipiv,
                                    armpl_int_t *ipiv2,
                                    armpl_singlecomplex_t *b,
                                    armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_aa_2stage* and *LAPACKE_zhesv_aa_2stage*. It also exists with a native Fortran interface as *chesv_aa_2stage*.

4.19.232 LAPACKE_chesv_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesv_aa_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  armpl_singlecomplex_t *a, armpl_int_t lda,
                                  armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                                  armpl_int_t ldb,
                                  armpl_singlecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_aa_work* and *LAPACKE_zhesv_aa_work*.

4.19.233 LAPACKE_chesv_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesv_rk(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             armpl_singlecomplex_t *a, armpl_int_t lda,
                             armpl_singlecomplex_t *e, armpl_int_t *ipiv,
                             armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_rk* and *LAPACKE_zhesv_rk*. It also exists with a native Fortran interface as *chesv_rk*.

4.19.234 LAPACKE_chesv_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesv_rk_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  armpl_singlecomplex_t *a, armpl_int_t lda,
                                  armpl_singlecomplex_t *e, armpl_int_t *ipiv,
                                  armpl_singlecomplex_t *b, armpl_int_t ldb,
                                  armpl_singlecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_rk_work* and *LAPACKE_zhesv_rk_work*.

4.19.235 LAPACKE_chesv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                               armpl_int_t ldb, armpl_singlecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_work* and *LAPACKE_zhesv_work*.

4.19.236 LAPACKE_chesvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, const armpl_singlecomplex_t *b,
                           armpl_int_t ldb, armpl_singlecomplex_t *x,
                           armpl_int_t ldx, float *rcond, float *ferr,
                           float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesvx* and *LAPACKE_zhesvx*. It also exists with a native Fortran interface as *chesvx*.

4.19.237 LAPACKE_chesvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *af,
                                armpl_int_t ldaf, armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.238 LAPACKE_chesvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs,
                            armpl_singlecomplex_t *a, armpl_int_t lda,
                            armpl_singlecomplex_t *af, armpl_int_t ldaf,
                            armpl_int_t *ipiv, char *equed, float *s,
                            armpl_singlecomplex_t *b, armpl_int_t ldb,
                            armpl_singlecomplex_t *x, armpl_int_t ldx,
```

(continues on next page)

(continued from previous page)

```
                                float *rcond, float *rpvgrw, float *berr,
                                armpl_int_t n_err_bnds, float *err_bnds_norm,
                                float *err_bnds_comp, armpl_int_t nparams,
                                float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesvxx* and *LAPACKE_zhesvxx*. It also exists with a native Fortran interface as *chesvxx*.

4.19.239 LAPACKE_chesvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chesvxx_work(armpl_int_t matrix_layout, char fact,
                                 char uplo, armpl_int_t n, armpl_int_t nrhs,
                                 armpl_singlecomplex_t *a, armpl_int_t lda,
                                 armpl_singlecomplex_t *af, armpl_int_t ldaf,
                                 armpl_int_t *ipiv, char *equed, float *s,
                                 armpl_singlecomplex_t *b, armpl_int_t ldb,
                                 armpl_singlecomplex_t *x, armpl_int_t ldx,
                                 float *rcond, float *rpvgrw, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, armpl_singlecomplex_t *work,
                                 float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.240 LAPACKE_cheswapr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheswapr(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_singlecomplex_t *a,
                             armpl_int_t lda, armpl_int_t i1,
                             armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheswapr* and *LAPACKE_zheswapr*. It also exists with a native Fortran interface as *cheswapr*.

4.19.241 LAPACKE_cheswapr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cheswapr_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_singlecomplex_t *a,
                                  armpl_int_t lda, armpl_int_t i1,
                                  armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheswapr_work* and *LAPACKE_zheswapr_work*.

4.19.242 LAPACKE_chetrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrd(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, float *d, float *e,
                           armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrd* and *LAPACKE_zhetrd*. It also exists with a native Fortran interface as *chetrd*.

4.19.243 LAPACKE_chetrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrd_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, float *d, float *e,
                                armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrd_work* and *LAPACKE_zhetrd_work*.

4.19.244 LAPACKE_chetrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf* and *LAPACKE_zhetrf*. It also exists with a native Fortran interface as *chetrf*.

4.19.245 LAPACKE_chetrf_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrf_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_singlecomplex_t *a,
                              armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_aa* and *LAPACKE_zhetrf_aa*. It also exists with a native Fortran interface as *chetrf_aa*.

4.19.246 LAPACKE_chetrf_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrf_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_singlecomplex_t *a,
                                     armpl_int_t lda,
                                     armpl_singlecomplex_t *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_aa_2stage* and *LAPACKE_zhetrf_aa_2stage*. It also exists with a native Fortran interface as *chetrf_aa_2stage*.

4.19.247 LAPACKE_chetrf_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrf_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_singlecomplex_t *a,
                                   armpl_int_t lda, armpl_int_t *ipiv,
                                   armpl_singlecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_aa_work* and *LAPACKE_zhetrf_aa_work*.

4.19.248 LAPACKE_chetrf_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrf_rk(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_singlecomplex_t *a,
                              armpl_int_t lda, armpl_singlecomplex_t *e,
                              armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_rk* and *LAPACKE_zhetrf_rk*. It also exists with a native Fortran interface as *chetrf_rk*.

4.19.249 LAPACKE_chetrf_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrf_rk_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_singlecomplex_t *a,
                                   armpl_int_t lda, armpl_singlecomplex_t *e,
                                   armpl_int_t *ipiv,
                                   armpl_singlecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_rk_work* and *LAPACKE_zhetrf_rk_work*.

4.19.250 LAPACKE_chetrf_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrf_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_rook* and *LAPACKE_zhetrf_rook*. It also exists with a native Fortran interface as *chetrf_rook*.

4.19.251 LAPACKE_chetrf_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrf_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_singlecomplex_t *a,
                                     armpl_int_t lda, armpl_int_t *ipiv,
                                     armpl_singlecomplex_t *work,
                                     armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_rook_work* and *LAPACKE_zhetrf_rook_work*.

4.19.252 LAPACKE_chetrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_work* and *LAPACKE_zhetrf_work*.

4.19.253 LAPACKE_chetri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri* and *LAPACKE_zhetri*. It also exists with a native Fortran interface as *chetri*.

4.19.254 LAPACKE_chetri2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetri2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_singlecomplex_t *a,
                            armpl_int_t lda, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri2* and *LAPACKE_zhetri2*. It also exists with a native Fortran interface as *chetri2*.

4.19.255 LAPACKE_chetri2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetri2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, const armpl_int_t *ipiv,
                                 armpl_singlecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri2_work* and *LAPACKE_zhetri2_work*.

4.19.256 LAPACKE_chetri2x

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetri2x(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_singlecomplex_t *a,
                             armpl_int_t lda, const armpl_int_t *ipiv,
                             armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri2x* and *LAPACKE_zhetri2x*. It also exists with a native Fortran interface as *chetri2x*.

4.19.257 LAPACKE_chetri2x_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetri2x_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_singlecomplex_t *a,
                                  armpl_int_t lda, const armpl_int_t *ipiv,
                                  armpl_singlecomplex_t *work,
                                  armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri2x_work* and *LAPACKE_zhetri2x_work*.

4.19.258 LAPACKE_chetri_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetri_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_singlecomplex_t *a,
                             armpl_int_t lda, const armpl_singlecomplex_t *e,
                             const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri_3* and *LAPACKE_zhetri_3*. It also exists with a native Fortran interface as *chetri_3*.

4.19.259 LAPACKE_chetri_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetri_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_singlecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_singlecomplex_t *e,
                                  const armpl_int_t *ipiv,
                                  armpl_singlecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri_3_work* and *LAPACKE_zhetri_3_work*.

4.19.260 LAPACKE_chetri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri_work* and *LAPACKE_zhetri_work*.

4.19.261 LAPACKE_chetrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs* and *LAPACKE_zhetrs*. It also exists with a native Fortran interface as *chetrs*.

4.19.262 LAPACKE_chetrs2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_int_t nrhs,
                            const armpl_singlecomplex_t *a, armpl_int_t lda,
                            const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                            armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs2* and *LAPACKE_zhetrs2*. It also exists with a native Fortran interface as *chetrs2*.

4.19.263 LAPACKE_chetrs2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_int_t nrhs,
                                 const armpl_singlecomplex_t *a,
                                 armpl_int_t lda, const armpl_int_t *ipiv,
                                 armpl_singlecomplex_t *b, armpl_int_t ldb,
                                 armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs2_work* and *LAPACKE_zhetrs2_work*.

4.19.264 LAPACKE_chetrs_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             const armpl_singlecomplex_t *a, armpl_int_t lda,
                             const armpl_singlecomplex_t *e,
                             const armpl_int_t *ipiv,
                             armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_3* and *LAPACKE_zhetrs_3*. It also exists with a native Fortran interface as *chetrs_3*.

4.19.265 LAPACKE_chetrs_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  const armpl_singlecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_singlecomplex_t *e,
                                  const armpl_int_t *ipiv,
                                  armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_3_work* and *LAPACKE_zhetrs_3_work*.

4.19.266 LAPACKE_chetrs_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_int_t nrhs,
                              const armpl_singlecomplex_t *a, armpl_int_t lda,
                              const armpl_int_t *ipiv,
                              armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_aa* and *LAPACKE_zhetrs_aa*. It also exists with a native Fortran interface as *chetrs_aa*.

4.19.267 LAPACKE_chetrs_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     armpl_singlecomplex_t *a,
                                     armpl_int_t lda,
                                     armpl_singlecomplex_t *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2,
                                     armpl_singlecomplex_t *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_aa_2stage* and *LAPACKE_zhetrs_aa_2stage*. It also exists with a native Fortran interface as *chetrs_aa_2stage*.

4.19.268 LAPACKE_chetrs_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_int_t nrhs,
                                   const armpl_singlecomplex_t *a,
                                   armpl_int_t lda, const armpl_int_t *ipiv,
                                   armpl_singlecomplex_t *b, armpl_int_t ldb,
                                   armpl_singlecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_aa_work* and *LAPACKE_zhetrs_aa_work*.

4.19.269 LAPACKE_chetrs_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_rook* and *LAPACKE_zhetrs_rook*. It also exists with a native Fortran interface as *chetrs_rook*.

4.19.270 LAPACKE_chetrs_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     const armpl_singlecomplex_t *a,
                                     armpl_int_t lda, const armpl_int_t *ipiv,
                                     armpl_singlecomplex_t *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_rook_work* and *LAPACKE_zhetrs_rook_work*.

4.19.271 LAPACKE_chetrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chetrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.272 LAPACKE_chfrk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chfrk(armpl_int_t matrix_layout, char transr, char uplo,
                          char trans, armpl_int_t n, armpl_int_t k,
                          float alpha, const armpl_singlecomplex_t *a,
                          armpl_int_t lda, float beta,
                          armpl_singlecomplex_t *c);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chfrk* and *LAPACKE_zhfrk*. It also exists with a native Fortran interface as *chfrk*.

4.19.273 LAPACKE_chfrk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chfrk_work(armpl_int_t matrix_layout, char transr,
                               char uplo, char trans, armpl_int_t n,
                               armpl_int_t k, float alpha,
                               const armpl_singlecomplex_t *a,
                               armpl_int_t lda, float beta,
                               armpl_singlecomplex_t *c);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chfrk_work* and *LAPACKE_zhfrk_work*.

4.19.274 LAPACKE_chgeqz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chgeqz(armpl_int_t matrix_layout, char job, char compq,
                           char compz, armpl_int_t n, armpl_int_t ilo,
                           armpl_int_t ihi, armpl_singlecomplex_t *h,
                           armpl_int_t ldh, armpl_singlecomplex_t *t,
                           armpl_int_t ldt, armpl_singlecomplex_t *alpha,
                           armpl_singlecomplex_t *beta,
                           armpl_singlecomplex_t *q, armpl_int_t ldq,
                           armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chgeqz*, *LAPACKE_dhgeqz*, *LAPACKE_shgeqz* and *LAPACKE_zhgeqz*. It also exists with a native Fortran interface as *chgeqz*.

4.19.275 LAPACKE_chgeqz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chgeqz_work(armpl_int_t matrix_layout, char job,

```
                                armpl_int_t ilo, armpl_int_t ihi,
                                armpl_singlecomplex_t *h, armpl_int_t ldh,
                                armpl_singlecomplex_t *t, armpl_int_t ldt,
                                armpl_singlecomplex_t *alpha,
                                armpl_singlecomplex_t *beta,
                                armpl_singlecomplex_t *q, armpl_int_t ldq,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chgeqz_work*, *LAPACKE_dhgeqz_work*, *LAPACKE_shgeqz_work* and *LAPACKE_zhgeqz_work*.

4.19.276 LAPACKE_chpcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *ap,
                           const armpl_int_t *ipiv, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpcon* and *LAPACKE_zhpcon*. It also exists with a native Fortran interface as *chpcon*.

4.19.277 LAPACKE_chpcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_singlecomplex_t *ap,
                                const armpl_int_t *ipiv, float anorm,
                                float *rcond, armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpcon_work* and *LAPACKE_zhpcon_work*.

4.19.278 LAPACKE_chpev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_singlecomplex_t *ap, float *w,
                          armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpev* and *LAPACKE_zhpev*. It also exists with a native Fortran interface as *chpev*.

4.19.279 LAPACKE_chpev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n,
                               armpl_singlecomplex_t *ap, float *w,
                               armpl_singlecomplex_t *z, armpl_int_t ldz,
                               armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpev_work* and *LAPACKE_zhpev_work*.

4.19.280 LAPACKE_chpevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *ap, float *w,
                           armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpevd* and *LAPACKE_zhpevd*. It also exists with a native Fortran interface as *chpevd*.

4.19.281 LAPACKE_chpevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *ap, float *w,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpevd_work* and *LAPACKE_zhpevd_work*.

4.19.282 LAPACKE_chpevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n,
                           armpl_singlecomplex_t *ap, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, armpl_singlecomplex_t *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.283 LAPACKE_chpevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *ap, float vl, float vu,
                                armpl_int_t il, armpl_int_t iu, float abstol,
                                armpl_int_t *m, float *w,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work, float *rwork,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpevx_work* and *LAPACKE_zhpevx_work*.

4.19.284 LAPACKE_chpgst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpgst(armpl_int_t matrix_layout, armpl_int_t itype,
                           char uplo, armpl_int_t n,
                           armpl_singlecomplex_t *ap,
                           const armpl_singlecomplex_t *bp);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgst* and *LAPACKE_zhpgst*. It also exists with a native Fortran interface as *chpgst*.

4.19.285 LAPACKE_chpgst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpgst_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *ap,
                                const armpl_singlecomplex_t *bp);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgst_work* and *LAPACKE_zhpgst_work*.

4.19.286 LAPACKE_chpgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpgv(armpl_int_t matrix_layout, armpl_int_t itype,
                          char jobz, char uplo, armpl_int_t n,
                          armpl_singlecomplex_t *ap,
                          armpl_singlecomplex_t *bp, float *w,
                          armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgv* and *LAPACKE_zhpgv*. It also exists with a native Fortran interface as *chpgv*.

4.19.287 LAPACKE_chpgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpgv_work(armpl_int_t matrix_layout, armpl_int_t itype,
                               char jobz, char uplo, armpl_int_t n,
                               armpl_singlecomplex_t *ap,
                               armpl_singlecomplex_t *bp, float *w,
                               armpl_singlecomplex_t *z, armpl_int_t ldz,
                               armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgv_work* and *LAPACKE_zhpgv_work*.

4.19.288 LAPACKE_chpgvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpgvd(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char uplo, armpl_int_t n,
                           armpl_singlecomplex_t *ap,
                           armpl_singlecomplex_t *bp, float *w,
                           armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgvd* and *LAPACKE_zhpgvd*. It also exists with a native Fortran interface as *chpgvd*.

4.19.289 LAPACKE_chpgvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpgvd_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *ap,
                                armpl_singlecomplex_t *bp, float *w,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgvd_work* and *LAPACKE_zhpgvd_work*.

4.19.290 LAPACKE_chpgvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpgvx(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char range, char uplo, armpl_int_t n,
                           armpl_singlecomplex_t *ap,
                           armpl_singlecomplex_t *bp, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, armpl_singlecomplex_t *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgvx* and *LAPACKE_zhpgvx*. It also exists with a native Fortran interface as *chpgvx*.

4.19.291 LAPACKE_chpgvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpgvx_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char range, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *ap,
                                armpl_singlecomplex_t *bp, float vl, float vu,
                                armpl_int_t il, armpl_int_t iu, float abstol,
                                armpl_int_t *m, float *w,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work, float *rwork,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.292 LAPACKE_chprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           const armpl_singlecomplex_t *afp,
                           const armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
```

(continues on next page)

(continued from previous page)

```
                                armpl_singlecomplex_t *x, armpl_int_t ldx,
                                float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chprfs* and *LAPACKE_zhprfs*. It also exists with a native Fortran interface as *chprfs*.

4.19.293 LAPACKE_chprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                const armpl_singlecomplex_t *afp,
                                const armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chprfs_work* and *LAPACKE_zhprfs_work*.

4.19.294 LAPACKE_chpsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_singlecomplex_t *ap,
                          armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpsv* and *LAPACKE_zhpsv*. It also exists with a native Fortran interface as *chpsv*.

4.19.295 LAPACKE_chpsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_singlecomplex_t *ap, armpl_int_t *ipiv,
                               armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpsv_work* and *LAPACKE_zhpsv_work*.

4.19.296 LAPACKE_chpsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           armpl_singlecomplex_t *afp, armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpsvx* and *LAPACKE_zhpsvx*. It also exists with a native Fortran interface as *chpsvx*.

4.19.297 LAPACKE_chpsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chpsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                armpl_singlecomplex_t *afp, armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpsvx_work* and *LAPACKE_zhpsvx_work*.

4.19.298 LAPACKE_chptrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chptrd(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *ap, float *d,
                           float *e, armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrd* and *LAPACKE_zhptrd*. It also exists with a native Fortran interface as *chptrd*.

4.19.299 LAPACKE_chptrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chptrd_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *ap,
                                float *d, float *e,
                                armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrd_work* and *LAPACKE_zhptrd_work*.

4.19.300 LAPACKE_chptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *ap,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrf* and *LAPACKE_zhptrf*. It also exists with a native Fortran interface as *chptrf*.

4.19.301 LAPACKE_chptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *ap,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrf_work* and *LAPACKE_zhptrf_work*.

4.19.302 LAPACKE_chptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *ap,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptri* and *LAPACKE_zhptri*. It also exists with a native Fortran interface as *chptri*.

4.19.303 LAPACKE_chptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *ap,
                                const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptri_work* and *LAPACKE_zhptri_work*.

4.19.304 LAPACKE_chptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrs* and *LAPACKE_zhptrs*. It also exists with a native Fortran interface as *chptrs*.

4.19.305 LAPACKE_chptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrs_work* and *LAPACKE_zhptrs_work*.

4.19.306 LAPACKE_chsein

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chsein(armpl_int_t matrix_layout, char job, char eigsrc,
                           char initv, const armpl_int_t *select,
                           armpl_int_t n, const armpl_singlecomplex_t *h,
                           armpl_int_t ldh, armpl_singlecomplex_t *w,
                           armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                           armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t mm, armpl_int_t *m,
                           armpl_int_t *ifaill, armpl_int_t *ifailr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chsein*, *LAPACKE_dhsein*, *LAPACKE_shsein* and *LAPACKE_zhsein*. It also exists with a native Fortran interface as *chsein*.

4.19.307 LAPACKE_chsein_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chsein_work(armpl_int_t matrix_layout, char job,
                                char eigsrc, char initv,
                                const armpl_int_t *select, armpl_int_t n,
                                const armpl_singlecomplex_t *h,
                                armpl_int_t ldh, armpl_singlecomplex_t *w,
                                armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                                armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                                armpl_int_t mm, armpl_int_t *m,
                                armpl_singlecomplex_t *work, float *rwork,
                                armpl_int_t *ifaill, armpl_int_t *ifailr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chsein_work*, *LAPACKE_dhsein_work*, *LAPACKE_shsein_work* and *LAPACKE_zhsein_work*.

4.19.308 LAPACKE_chseqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chseqr(armpl_int_t matrix_layout, char job, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           armpl_singlecomplex_t *h, armpl_int_t ldh,
                           armpl_singlecomplex_t *w, armpl_singlecomplex_t *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chseqr*, *LAPACKE_dhseqr*, *LAPACKE_shseqr* and *LAPACKE_zhseqr*. It also exists with a native Fortran interface as *chseqr*.

4.19.309 LAPACKE_chseqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_chseqr_work(armpl_int_t matrix_layout, char job,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, armpl_singlecomplex_t *h,
                                armpl_int_t ldh, armpl_singlecomplex_t *w,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chseqr_work*, *LAPACKE_dhseqr_work*, *LAPACKE_shseqr_work* and *LAPACKE_zhseqr_work*.

4.19.310 LAPACKE_clacgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacgv(armpl_int_t n, armpl_singlecomplex_t *x,
                           armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacgv* and *LAPACKE_zlacgv*. It also exists with a native Fortran interface as *clacgv*.

4.19.311 LAPACKE_clacgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacgv_work(armpl_int_t n, armpl_singlecomplex_t *x,
                                armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacgv_work* and *LAPACKE_zlacgv_work*.

4.19.312 LAPACKE_clacn2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacn2(armpl_int_t n, armpl_singlecomplex_t *v,
                           armpl_singlecomplex_t *x, float *est,
                           armpl_int_t *kase, armpl_int_t *isave);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacn2*, *LAPACKE_dlacn2*, *LAPACKE_slacn2* and *LAPACKE_zlacn2*. It also exists with a native Fortran interface as *clacn2*.

4.19.313 LAPACKE_clacn2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacn2_work(armpl_int_t n, armpl_singlecomplex_t *v,
                                armpl_singlecomplex_t *x, float *est,
                                armpl_int_t *kase, armpl_int_t *isave);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacn2_work*, *LAPACKE_dlacn2_work*, *LAPACKE_slacn2_work* and *LAPACKE_zlacn2_work*.

4.19.314 LAPACKE_clacp2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacp2(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n, const float *a,
                           armpl_int_t lda, armpl_singlecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacp2* and *LAPACKE_zlacp2*. It also exists with a native Fortran interface as *clacp2*.

4.19.315 LAPACKE_clacp2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacp2_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n, const float *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacp2_work* and *LAPACKE_zlacp2_work*.

4.19.316 LAPACKE_clacpy

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacpy(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacpy*, *LAPACKE_dlacpy*, *LAPACKE_slacpy* and *LAPACKE_zlacpy*. It also exists with a native Fortran interface as *clacpy*.

4.19.317 LAPACKE_clacpy_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacpy_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacpy_work*, *LAPACKE_dlacpy_work*, *LAPACKE_slacpy_work* and *LAPACKE_zlacpy_work*.

4.19.318 LAPACKE_clacrm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacrm(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, const float *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacrm* and *LAPACKE_zlacrm*. It also exists with a native Fortran interface as *clacrm*.

4.19.319 LAPACKE_clacrm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clacrm_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda, const float *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *c,
                                armpl_int_t ldc, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacrm_work* and *LAPACKE_zlacrm_work*.

4.19.320 LAPACKE_clag2z

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clag2z(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const armpl_singlecomplex_t *sa,
                           armpl_int_t ldsa, armpl_doublecomplex_t *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clag2z*. It also exists with a native Fortran interface as *clag2z*.

4.19.321 LAPACKE_clag2z_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clag2z_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n,
                                const armpl_singlecomplex_t *sa,
                                armpl_int_t ldsa, armpl_doublecomplex_t *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clag2z_work*.

4.19.328 LAPACKE_clange

Syntax

```
#include "armpl.h"

float LAPACKE_clange(armpl_int_t matrix_layout, char norm, armpl_int_t m,
                     armpl_int_t n, const armpl_singlecomplex_t *a,
                     armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clange*, *LAPACKE_dlange*, *LAPACKE_slange* and *LAPACKE_zlange*. It also exists with a native Fortran interface as *clange*.

4.19.329 LAPACKE_clange_work

Syntax

```
#include "armpl.h"

float LAPACKE_clange_work(armpl_int_t matrix_layout, char norm, armpl_int_t m,
                          armpl_int_t n, const armpl_singlecomplex_t *a,
                          armpl_int_t lda, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clange_work*, *LAPACKE_dlange_work*, *LAPACKE_slange_work* and *LAPACKE_zlange_work*.

4.19.330 LAPACKE_clanhe

Syntax

```
#include "armpl.h"

float LAPACKE_clanhe(armpl_int_t matrix_layout, char norm, char uplo,
                     armpl_int_t n, const armpl_singlecomplex_t *a,
                     armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clanhe* and *LAPACKE_zlanhe*. It also exists with a native Fortran interface as *clanhe*.

4.19.331 LAPACKE_clanhe_work

Syntax

```
#include "armpl.h"

float LAPACKE_clanhe_work(armpl_int_t matrix_layout, char norm, char uplo,
                          armpl_int_t n, const armpl_singlecomplex_t *a,
                          armpl_int_t lda, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clanhe_work* and *LAPACKE_zlanhe_work*.

4.19.332 LAPACKE_clansy

Syntax

```
#include "armpl.h"

float LAPACKE_clansy(armpl_int_t matrix_layout, char norm, char uplo,
                     armpl_int_t n, const armpl_singlecomplex_t *a,
                     armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clansy*, *LAPACKE_dlansy*, *LAPACKE_slansy* and *LAPACKE_zlansy*. It also exists with a native Fortran interface as *clansy*.

4.19.333 LAPACKE_clansy_work

Syntax

```
#include "armpl.h"

float LAPACKE_clansy_work(armpl_int_t matrix_layout, char norm, char uplo,
                          armpl_int_t n, const armpl_singlecomplex_t *a,
                          armpl_int_t lda, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clansy_work*, *LAPACKE_dlansy_work*, *LAPACKE_slansy_work* and *LAPACKE_zlansy_work*.

4.19.334 LAPACKE_clantr

Syntax

```
#include "armpl.h"

float LAPACKE_clantr(armpl_int_t matrix_layout, char norm, char uplo,
                     char diag, armpl_int_t m, armpl_int_t n,
                     const armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clantr*, *LAPACKE_dlantr*, *LAPACKE_slantr* and *LAPACKE_zlantr*. It also exists with a native Fortran interface as *clantr*.

4.19.335 LAPACKE_clantr_work

Syntax

```
#include "armpl.h"

float LAPACKE_clantr_work(armpl_int_t matrix_layout, char norm, char uplo,
                          char diag, armpl_int_t m, armpl_int_t n,
                          const armpl_singlecomplex_t *a, armpl_int_t lda,
                          float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clantr_work*, *LAPACKE_dlantr_work*, *LAPACKE_slantr_work* and *LAPACKE_zlantr_work*.

4.19.336 LAPACKE_clapmr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clapmr(armpl_int_t matrix_layout, armpl_int_t forwrd,
                           armpl_int_t m, armpl_int_t n,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmr*, *LAPACKE_dlapmr*, *LAPACKE_slapmr* and *LAPACKE_zlapmr*. It also exists with a native Fortran interface as *clapmr*.

4.19.337 LAPACKE_clapmr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clapmr_work(armpl_int_t matrix_layout, armpl_int_t forwrd,
                                armpl_int_t m, armpl_int_t n,
                                armpl_singlecomplex_t *x, armpl_int_t ldx,
                                armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmr_work*, *LAPACKE_dlapmr_work*, *LAPACKE_slapmr_work* and *LAPACKE_zlapmr_work*.

4.19.338 LAPACKE_clapmt

4.19.339 LAPACKE_clapmt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clapmt_work(armpl_int_t matrix_layout, armpl_int_t forwrd,
                                armpl_int_t m, armpl_int_t n,
                                armpl_singlecomplex_t *x, armpl_int_t ldx,
                                armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmt_work*, *LAPACKE_dlapmt_work*, *LAPACKE_slapmt_work* and *LAPACKE_zlapmt_work*.

4.19.340 LAPACKE_clarcm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarcm(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const float *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarcm* and *LAPACKE_zlarcm*. It also exists with a native Fortran interface as *clarcm*.

4.19.341 LAPACKE_clarcm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarcm_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *c,
                                armpl_int_t ldc, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarcm_work* and *LAPACKE_zlarcm_work*.

4.19.342 LAPACKE_clarfb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarfb(armpl_int_t matrix_layout, char side, char trans,
                           char direct, char storev, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           const armpl_singlecomplex_t *v, armpl_int_t ldv,
                           const armpl_singlecomplex_t *t, armpl_int_t ldt,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfb*, *LAPACKE_dlarfb*, *LAPACKE_slarfb* and *LAPACKE_zlarfb*. It also exists with a native Fortran interface as *clarfb*.

4.19.343 LAPACKE_clarfb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarfb_work(armpl_int_t matrix_layout, char side,
                                char trans, char direct, char storev,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                const armpl_singlecomplex_t *v,
                                armpl_int_t ldv,
                                const armpl_singlecomplex_t *t,
                                armpl_int_t ldt, armpl_singlecomplex_t *c,
                                armpl_int_t ldc, armpl_singlecomplex_t *work,
                                armpl_int_t ldwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfb_work*, *LAPACKE_dlarfb_work*, *LAPACKE_slarfb_work* and *LAPACKE_zlarfb_work*.

4.19.344 LAPACKE_clarfg

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarfg(armpl_int_t n, armpl_singlecomplex_t *alpha,
                           armpl_singlecomplex_t *x, armpl_int_t incx,
                           armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfg*, *LAPACKE_dlarfg*, *LAPACKE_slarfg* and *LAPACKE_zlarfg*. It also exists with a native Fortran interface as *clarfg*.

4.19.345 LAPACKE_clarfg_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarfg_work(armpl_int_t n, armpl_singlecomplex_t *alpha,
                                armpl_singlecomplex_t *x, armpl_int_t incx,
                                armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfg_work*, *LAPACKE_dlarfg_work*, *LAPACKE_slarfg_work* and *LAPACKE_zlarfg_work*.

4.19.346 LAPACKE_clarft

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarft(armpl_int_t matrix_layout, char direct,
                           char storev, armpl_int_t n, armpl_int_t k,
                           const armpl_singlecomplex_t *v, armpl_int_t ldv,
                           const armpl_singlecomplex_t *tau,
                           armpl_singlecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarft*, *LAPACKE_dlarft*, *LAPACKE_slarft* and *LAPACKE_zlarft*. It also exists with a native Fortran interface as *clarft*.

4.19.347 LAPACKE_clarft_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarft_work(armpl_int_t matrix_layout, char direct,
                                char storev, armpl_int_t n, armpl_int_t k,
                                const armpl_singlecomplex_t *v,
                                armpl_int_t ldv,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarft_work*, *LAPACKE_dlarft_work*, *LAPACKE_slarft_work* and *LAPACKE_zlarft_work*.

4.19.348 LAPACKE_clarfx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarfx(armpl_int_t matrix_layout, char side,
                           armpl_int_t m, armpl_int_t n,
                           const armpl_singlecomplex_t *v,
                           armpl_singlecomplex_t tau,
                           armpl_singlecomplex_t *c, armpl_int_t ldc,
                           armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfx*, *LAPACKE_dlarfx*, *LAPACKE_slarfx* and *LAPACKE_zlarfx*. It also exists with a native Fortran interface as *clarfx*.

4.19.349 LAPACKE_clarfx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarfx_work(armpl_int_t matrix_layout, char side,
                                armpl_int_t m, armpl_int_t n,
                                const armpl_singlecomplex_t *v,
                                armpl_singlecomplex_t tau,
                                armpl_singlecomplex_t *c, armpl_int_t ldc,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfx_work*, *LAPACKE_dlarfx_work*, *LAPACKE_slarfx_work* and *LAPACKE_zlarfx_work*.

4.19.350 LAPACKE_clarnv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarnv(armpl_int_t idist, armpl_int_t *iseed,
                           armpl_int_t n, armpl_singlecomplex_t *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarnv*, *LAPACKE_dlarnv*, *LAPACKE_slarnv* and *LAPACKE_zlarnv*. It also exists with a native Fortran interface as *clarnv*.

4.19.351 LAPACKE_clarnv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clarnv_work(armpl_int_t idist, armpl_int_t *iseed,
                                armpl_int_t n, armpl_singlecomplex_t *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarnv_work*, *LAPACKE_dlarnv_work*, *LAPACKE_slarnv_work* and *LAPACKE_zlarnv_work*.

4.19.352 LAPACKE_clascl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clascl(armpl_int_t matrix_layout, char type,
                           armpl_int_t kl, armpl_int_t ku, float cfrom,
                           float cto, armpl_int_t m, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clascl*, *LAPACKE_dlascl*, *LAPACKE_slascl* and *LAPACKE_zlascl*. It also exists with a native Fortran interface as *clascl*.

4.19.353 LAPACKE_clascl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clascl_work(armpl_int_t matrix_layout, char type,
                                armpl_int_t kl, armpl_int_t ku, float cfrom,
                                float cto, armpl_int_t m, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clascl_work*, *LAPACKE_dlascl_work*, *LAPACKE_slascl_work* and *LAPACKE_zlascl_work*.

4.19.354 LAPACKE_claset

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_claset(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n,
                           armpl_singlecomplex_t alpha,
                           armpl_singlecomplex_t beta,
                           armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claset*, *LAPACKE_dlaset*, *LAPACKE_slaset* and *LAPACKE_zlaset*. It also exists with a native Fortran interface as *claset*.

4.19.355 LAPACKE_claset_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_claset_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n,
                                armpl_singlecomplex_t alpha,
                                armpl_singlecomplex_t beta,
                                armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claset_work*, *LAPACKE_dlaset_work*, *LAPACKE_slaset_work* and *LAPACKE_zlaset_work*.

4.19.356 LAPACKE_classq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_classq(armpl_int_t n, armpl_singlecomplex_t *x,
                           armpl_int_t incx, float *scale, float *sumsq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_classq*, *LAPACKE_dlassq*, *LAPACKE_slassq* and *LAPACKE_zlassq*. It also exists with a native Fortran interface as *classq*.

4.19.357 LAPACKE_classq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_classq_work(armpl_int_t n, armpl_singlecomplex_t *x,
                                armpl_int_t incx, float *scale,
                                float *sumsq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_classq_work*, *LAPACKE_dlassq_work*, *LAPACKE_slassq_work* and *LAPACKE_zlassq_work*.

4.19.358 LAPACKE_claswp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_claswp(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_int_t k1, armpl_int_t k2,
                           const armpl_int_t *ipiv, armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claswp*, *LAPACKE_dlaswp*, *LAPACKE_slaswp* and *LAPACKE_zlaswp*. It also exists with a native Fortran interface as *claswp*.

4.19.359 LAPACKE_claswp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_claswp_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_int_t k1, armpl_int_t k2,
                                const armpl_int_t *ipiv, armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claswp_work*, *LAPACKE_dlaswp_work*, *LAPACKE_slaswp_work* and *LAPACKE_zlaswp_work*.

4.19.360 LAPACKE_clatms

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.361 LAPACKE_clatms_work

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.362 LAPACKE_clauum

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clauum(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clauum*, *LAPACKE_dlauum*, *LAPACKE_slauum* and *LAPACKE_zlauum*. It also exists with a native Fortran interface as *clauum*.

4.19.363 LAPACKE_clauum_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_clauum_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clauum_work*, *LAPACKE_dlauum_work*, *LAPACKE_slauum_work* and *LAPACKE_zlauum_work*.

4.19.364 LAPACKE_cpbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd,
                           const armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbcon*, *LAPACKE_dpbcon*, *LAPACKE_spbcon* and *LAPACKE_zpbcon*. It also exists with a native Fortran interface as *cpbcon*.

4.19.365 LAPACKE_cpbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, float anorm, float *rcond,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbcon_work*, *LAPACKE_dpbcon_work*, *LAPACKE_spbcon_work* and *LAPACKE_zpbcon_work*.

4.19.366 LAPACKE_cpbequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbequ(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd,
                           const armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           float *s, float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbequ*, *LAPACKE_dpbequ*, *LAPACKE_spbequ* and *LAPACKE_zpbequ*. It also exists with a native Fortran interface as *cpbequ*.

4.19.367 LAPACKE_cpbequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbequ_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, float *s, float *scond,
                                float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.368 LAPACKE_cpbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           const armpl_singlecomplex_t *afb,
                           armpl_int_t ldafb, const armpl_singlecomplex_t *b,
                           armpl_int_t ldb, armpl_singlecomplex_t *x,
                           armpl_int_t ldx, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbrfs*, *LAPACKE_dpbrfs*, *LAPACKE_spbrfs* and *LAPACKE_zpbrfs*. It also exists with a native Fortran interface as *cpbrfs*.

4.19.369 LAPACKE_cpbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab,
                                const armpl_singlecomplex_t *afb,
                                armpl_int_t ldafb,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.370 LAPACKE_cpbstf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbstf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kb,
                           armpl_singlecomplex_t *bb, armpl_int_t ldbb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbstf*, *LAPACKE_dpbstf*, *LAPACKE_spbstf* and *LAPACKE_zpbstf*. It also exists with a native Fortran interface as *cpbstf*.

4.19.371 LAPACKE_cpbstf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbstf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kb,
                                armpl_singlecomplex_t *bb, armpl_int_t ldbb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbstf_work*, *LAPACKE_dpbstf_work*, *LAPACKE_spbstf_work* and *LAPACKE_zpbstf_work*.

4.19.372 LAPACKE_cpbsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t kd, armpl_int_t nrhs,
                          armpl_singlecomplex_t *ab, armpl_int_t ldab,
                          armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsv*, *LAPACKE_dpbsv*, *LAPACKE_spbsv* and *LAPACKE_zpbsv*. It also exists with a native Fortran interface as *cpbsv*.

4.19.373 LAPACKE_cpbsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t kd,
                               armpl_int_t nrhs, armpl_singlecomplex_t *ab,
                               armpl_int_t ldab, armpl_singlecomplex_t *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsv_work*, *LAPACKE_dpbsv_work*, *LAPACKE_spbsv_work* and *LAPACKE_zpbsv_work*.

4.19.374 LAPACKE_cpbsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           armpl_singlecomplex_t *afb, armpl_int_t ldafb,
                           char *equed, float *s, armpl_singlecomplex_t *b,
                           armpl_int_t ldb, armpl_singlecomplex_t *x,
                           armpl_int_t ldx, float *rcond, float *ferr,
                           float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsvx*, *LAPACKE_dpbsvx*, *LAPACKE_spbsvx* and *LAPACKE_zpbsvx*. It also exists with a native Fortran interface as *cpbsvx*.

4.19.375 LAPACKE_cpbsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs, armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, armpl_singlecomplex_t *afb,
                                armpl_int_t ldafb, char *equed, float *s,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *x, armpl_int_t ldx,
```

(continues on next page)

(continued from previous page)

```
                                    float *rcond, float *ferr, float *berr,
                                    armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsvx_work*, *LAPACKE_dpbsvx_work*, *LAPACKE_spbsvx_work* and *LAPACKE_zpbsvx_work*.

4.19.376 LAPACKE_cpbtrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbtrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd,
                           armpl_singlecomplex_t *ab, armpl_int_t ldab);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrf*, *LAPACKE_dpbtrf*, *LAPACKE_spbtrf* and *LAPACKE_zpbtrf*. It also exists with a native Fortran interface as *cpbtrf*.

4.19.377 LAPACKE_cpbtrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbtrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_singlecomplex_t *ab, armpl_int_t ldab);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrf_work*, *LAPACKE_dpbtrf_work*, *LAPACKE_spbtrf_work* and *LAPACKE_zpbtrf_work*.

4.19.378 LAPACKE_cpbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbtrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrs*, *LAPACKE_dpbtrs*, *LAPACKE_spbtrs* and *LAPACKE_zpbtrs*. It also exists with a native Fortran interface as *cpbtrs*.

4.19.379 LAPACKE_cpbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpbtrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, armpl_singlecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrs_work*, *LAPACKE_dpbtrs_work*, *LAPACKE_spbtrs_work* and *LAPACKE_zpbtrs_work*.

4.19.380 LAPACKE_cpftrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpftrf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrf*, *LAPACKE_dpftrf*, *LAPACKE_spftrf* and *LAPACKE_zpftrf*. It also exists with a native Fortran interface as *cpftrf*.

4.19.381 LAPACKE_cpftrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpftrf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrf_work*, *LAPACKE_dpftrf_work*, *LAPACKE_spftrf_work* and *LAPACKE_zpftrf_work*.

4.19.382 LAPACKE_cpftri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpftri(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftri*, *LAPACKE_dpftri*, *LAPACKE_spftri* and *LAPACKE_zpftri*. It also exists with a native Fortran interface as *cpftri*.

4.19.383 LAPACKE_cpftri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpftri_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                armpl_singlecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftri_work*, *LAPACKE_dpftri_work*, *LAPACKE_spftri_work* and *LAPACKE_zpftri_work*.

4.19.384 LAPACKE_cpftrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpftrs(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrs*, *LAPACKE_dpftrs*, *LAPACKE_spftrs* and *LAPACKE_zpftrs*. It also exists with a native Fortran interface as *cpftrs*.

4.19.385 LAPACKE_cpftrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpftrs_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrs_work*, *LAPACKE_dpftrs_work*, *LAPACKE_spftrs_work* and *LAPACKE_zpftrs_work*.

4.19.386 LAPACKE_cpocon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpocon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.387 LAPACKE_cpocon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpocon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda, float anorm, float *rcond,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.388 LAPACKE_cpoequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpoequ(armpl_int_t matrix_layout, armpl_int_t n,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           float *s, float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.389 LAPACKE_cpoequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpoequ_work(armpl_int_t matrix_layout, armpl_int_t n,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, float *s, float *scond,
                                float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.390 LAPACKE_cpoequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpoequb(armpl_int_t matrix_layout, armpl_int_t n,
                            const armpl_singlecomplex_t *a, armpl_int_t lda,
                            float *s, float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.392 LAPACKE_cporfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cporfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *af, armpl_int_t ldaf,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfs*, *LAPACKE_dporfs*, *LAPACKE_sporfs* and *LAPACKE_zporfs*. It also exists with a native Fortran interface as *cporfs*.

4.19.393 LAPACKE_cporfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cporfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *af,
                                armpl_int_t ldaf,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.394 LAPACKE_cporfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cporfsx(armpl_int_t matrix_layout, char uplo, char equed,
                            armpl_int_t n, armpl_int_t nrhs,
                            const armpl_singlecomplex_t *a, armpl_int_t lda,
                            const armpl_singlecomplex_t *af, armpl_int_t ldaf,
                            const float *s, const armpl_singlecomplex_t *b,
                            armpl_int_t ldb, armpl_singlecomplex_t *x,
                            armpl_int_t ldx, float *rcond, float *berr,
                            armpl_int_t n_err_bnds, float *err_bnds_norm,
                            float *err_bnds_comp, armpl_int_t nparams,
                            float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfsx*, *LAPACKE_dporfsx*, *LAPACKE_sporfsx* and *LAPACKE_zporfsx*. It also exists with a native Fortran interface as *cporfsx*.

4.19.395 LAPACKE_cporfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cporfsx_work(armpl_int_t matrix_layout, char uplo,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const armpl_singlecomplex_t *a,
                                 armpl_int_t lda,
                                 const armpl_singlecomplex_t *af,
                                 armpl_int_t ldaf, const float *s,
                                 const armpl_singlecomplex_t *b,
                                 armpl_int_t ldb, armpl_singlecomplex_t *x,
                                 armpl_int_t ldx, float *rcond, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, armpl_singlecomplex_t *work,
                                 float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.396 LAPACKE_cposv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cposv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_singlecomplex_t *a,
                          armpl_int_t lda, armpl_singlecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposv*, *LAPACKE_dposv*, *LAPACKE_sposv* and *LAPACKE_zposv*. It also exists with a native Fortran interface as *cposv*.

4.19.397 LAPACKE_cposv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cposv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposv_work*, *LAPACKE_dposv_work*, *LAPACKE_sposv_work* and *LAPACKE_zposv_work*.

4.19.398 LAPACKE_cposvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cposvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *af, armpl_int_t ldaf,
                           char *equed, float *s, armpl_singlecomplex_t *b,
                           armpl_int_t ldb, armpl_singlecomplex_t *x,
                           armpl_int_t ldx, float *rcond, float *ferr,
                           float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposvx*, *LAPACKE_dposvx*, *LAPACKE_sposvx* and *LAPACKE_zposvx*. It also exists with a native Fortran interface as *cposvx*.

4.19.399 LAPACKE_cposvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cposvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *af, armpl_int_t ldaf,
                                char *equed, float *s,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *x, armpl_int_t ldx,
                                float *rcond, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.400 LAPACKE_cposvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cposvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs,
                            armpl_singlecomplex_t *a, armpl_int_t lda,
                            armpl_singlecomplex_t *af, armpl_int_t ldaf,
                            char *equed, float *s, armpl_singlecomplex_t *b,
                            armpl_int_t ldb, armpl_singlecomplex_t *x,
                            armpl_int_t ldx, float *rcond, float *rpvgrw,
                            float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposvxx*, *LAPACKE_dposvxx*, *LAPACKE_sposvxx* and *LAPACKE_zposvxx*. It also exists with a native Fortran interface as *cposvxx*.

4.19.401 LAPACKE_cposvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cposvxx_work(armpl_int_t matrix_layout, char fact,
                                 char uplo, armpl_int_t n, armpl_int_t nrhs,
                                 armpl_singlecomplex_t *a, armpl_int_t lda,
                                 armpl_singlecomplex_t *af, armpl_int_t ldaf,
                                 char *equed, float *s,

4.19.402 LAPACKE_cpotrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpotrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf*, *LAPACKE_dpotrf*, *LAPACKE_spotrf* and *LAPACKE_zpotrf*. It also exists with a native Fortran interface as *cpotrf*.

4.19.403 LAPACKE_cpotrf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpotrf2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_singlecomplex_t *a,
                            armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf2*, *LAPACKE_dpotrf2*, *LAPACKE_spotrf2* and *LAPACKE_zpotrf2*. It also exists with a native Fortran interface as *cpotrf2*.

4.19.404 LAPACKE_cpotrf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpotrf2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_singlecomplex_t *a,
                                 armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf2_work*, *LAPACKE_dpotrf2_work*, *LAPACKE_spotrf2_work* and *LAPACKE_zpotrf2_work*.

4.19.405 LAPACKE_cpotrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpotrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf_work*, *LAPACKE_dpotrf_work*, *LAPACKE_spotrf_work* and *LAPACKE_zpotrf_work*.

4.19.406 LAPACKE_cpotri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpotri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotri*, *LAPACKE_dpotri*, *LAPACKE_spotri* and *LAPACKE_zpotri*. It also exists with a native Fortran interface as *cpotri*.

4.19.407 LAPACKE_cpotri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpotri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotri_work*, *LAPACKE_dpotri_work*, *LAPACKE_spotri_work* and *LAPACKE_zpotri_work*.

4.19.408 LAPACKE_cpotrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpotrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrs*, *LAPACKE_dpotrs*, *LAPACKE_spotrs* and *LAPACKE_zpotrs*. It also exists with a native Fortran interface as *cpotrs*.

4.19.409 LAPACKE_cpotrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpotrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrs_work*, *LAPACKE_dpotrs_work*, *LAPACKE_spotrs_work* and *LAPACKE_zpotrs_work*.

4.19.410 LAPACKE_cppcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cppcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *ap,
                           float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppcon*, *LAPACKE_dppcon*, *LAPACKE_sppcon* and *LAPACKE_zppcon*. It also exists with a native Fortran interface as *cppcon*.

4.19.411 LAPACKE_cppcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cppcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_singlecomplex_t *ap, float anorm,
                                float *rcond, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppcon_work*, *LAPACKE_dppcon_work*, *LAPACKE_sppcon_work* and *LAPACKE_zppcon_work*.

4.19.412 LAPACKE_cppequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cppequ(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *ap,
                           float *s, float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppequ*, *LAPACKE_dppequ*, *LAPACKE_sppequ* and *LAPACKE_zppequ*. It also exists with a native Fortran interface as *cppequ*.

4.19.413 LAPACKE_cppequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cppequ_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_singlecomplex_t *ap, float *s,
                                float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppequ_work*, *LAPACKE_dppequ_work*, *LAPACKE_sppequ_work* and *LAPACKE_zppequ_work*.

4.19.414 LAPACKE_cpprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           const armpl_singlecomplex_t *afp,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpprfs*, *LAPACKE_dpprfs*, *LAPACKE_spprfs* and *LAPACKE_zpprfs*. It also exists with a native Fortran interface as *cpprfs*.

4.19.415 LAPACKE_cpprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                const armpl_singlecomplex_t *afp,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpprfs_work*, *LAPACKE_dpprfs_work*, *LAPACKE_spprfs_work* and *LAPACKE_zpprfs_work*.

4.19.416 LAPACKE_cppsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cppsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_singlecomplex_t *ap,
                          armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsv*, *LAPACKE_dppsv*, *LAPACKE_sppsv* and *LAPACKE_zppsv*. It also exists with a native Fortran interface as *cppsv*.

4.19.417 LAPACKE_cppsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cppsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_singlecomplex_t *ap,
                               armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsv_work*, *LAPACKE_dppsv_work*, *LAPACKE_sppsv_work* and *LAPACKE_zppsv_work*.

4.19.418 LAPACKE_cppsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cppsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_singlecomplex_t *ap,
                           armpl_singlecomplex_t *afp, char *equed, float *s,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsvx*, *LAPACKE_dppsvx*, *LAPACKE_sppsvx* and *LAPACKE_zppsvx*. It also exists with a native Fortran interface as *cppsvx*.

4.19.419 LAPACKE_cppsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cppsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                armpl_singlecomplex_t *ap,
                                armpl_singlecomplex_t *afp, char *equed,
                                float *s, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsvx_work*, *LAPACKE_dppsvx_work*, *LAPACKE_sppsvx_work* and *LAPACKE_zppsvx_work*.

4.19.420 LAPACKE_cpptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrf*, *LAPACKE_dpptrf*, *LAPACKE_spptrf* and *LAPACKE_zpptrf*. It also exists with a native Fortran interface as *cpptrf*.

4.19.421 LAPACKE_cpptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrf_work*, *LAPACKE_dpptrf_work*, *LAPACKE_spptrf_work* and *LAPACKE_zpptrf_work*.

4.19.422 LAPACKE_cpptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptri*, *LAPACKE_dpptri*, *LAPACKE_spptri* and *LAPACKE_zpptri*. It also exists with a native Fortran interface as *cpptri*.

4.19.423 LAPACKE_cpptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptri_work*, *LAPACKE_dpptri_work*, *LAPACKE_spptri_work* and *LAPACKE_zpptri_work*.

4.19.424 LAPACKE_cpptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrs*, *LAPACKE_dpptrs*, *LAPACKE_spptrs* and *LAPACKE_zpptrs*. It also exists with a native Fortran interface as *cpptrs*.

4.19.425 LAPACKE_cpptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrs_work*, *LAPACKE_dpptrs_work*, *LAPACKE_spptrs_work* and *LAPACKE_zpptrs_work*.

4.19.426 LAPACKE_cpstrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpstrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *piv,
                           armpl_int_t *rank, float tol);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpstrf*, *LAPACKE_dpstrf*, *LAPACKE_spstrf* and *LAPACKE_zpstrf*. It also exists with a native Fortran interface as *cpstrf*.

4.19.427 LAPACKE_cpstrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpstrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *piv,
                                armpl_int_t *rank, float tol, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpstrf_work*, *LAPACKE_dpstrf_work*, *LAPACKE_spstrf_work* and *LAPACKE_zpstrf_work*.

4.19.428 LAPACKE_cptcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cptcon(armpl_int_t n, const float *d,
                           const armpl_singlecomplex_t *e, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptcon*, *LAPACKE_dptcon*, *LAPACKE_sptcon* and *LAPACKE_zptcon*. It also exists with a native Fortran interface as *cptcon*.

4.19.429 LAPACKE_cptcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cptcon_work(armpl_int_t n, const float *d,
                                const armpl_singlecomplex_t *e, float anorm,
                                float *rcond, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptcon_work*, *LAPACKE_dptcon_work*, *LAPACKE_sptcon_work* and *LAPACKE_zptcon_work*.

4.19.430 LAPACKE_cpteqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpteqr(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, float *d, float *e,
                           armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpteqr*, *LAPACKE_dpteqr*, *LAPACKE_spteqr* and *LAPACKE_zpteqr*. It also exists with a native Fortran interface as *cpteqr*.

4.19.431 LAPACKE_cpteqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpteqr_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, float *d, float *e,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpteqr_work*, *LAPACKE_dpteqr_work*, *LAPACKE_spteqr_work* and *LAPACKE_zpteqr_work*.

4.19.432 LAPACKE_cptrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cptrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *d,
                           const armpl_singlecomplex_t *e, const float *df,
                           const armpl_singlecomplex_t *ef,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptrfs*, *LAPACKE_dptrfs*, *LAPACKE_sptrfs* and *LAPACKE_zptrfs*. It also exists with a native Fortran interface as *cptrfs*.

4.19.433 LAPACKE_cptrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cptrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *d,
                                const armpl_singlecomplex_t *e,
                                const float *df,
                                const armpl_singlecomplex_t *ef,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptrfs_work*, *LAPACKE_dptrfs_work*, *LAPACKE_sptrfs_work* and *LAPACKE_zptrfs_work*.

4.19.434 LAPACKE_cptsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cptsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, float *d,
                          armpl_singlecomplex_t *e, armpl_singlecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsv*, *LAPACKE_dptsv*, *LAPACKE_sptsv* and *LAPACKE_zptsv*. It also exists with a native Fortran interface as *cptsv*.

4.19.435 LAPACKE_cptsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cptsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, float *d,
                               armpl_singlecomplex_t *e,
                               armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsv_work*, *LAPACKE_dptsv_work*, *LAPACKE_sptsv_work* and *LAPACKE_zptsv_work*.

4.19.436 LAPACKE_cptsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cptsvx(armpl_int_t matrix_layout, char fact,
                           armpl_int_t n, armpl_int_t nrhs, const float *d,
                           const armpl_singlecomplex_t *e, float *df,
                           armpl_singlecomplex_t *ef,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.437 LAPACKE_cptsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cptsvx_work(armpl_int_t matrix_layout, char fact,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *d,
                                const armpl_singlecomplex_t *e, float *df,
                                armpl_singlecomplex_t *ef,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsvx_work*, *LAPACKE_dptsvx_work*, *LAPACKE_sptsvx_work* and *LAPACKE_zptsvx_work*.

4.19.438 LAPACKE_cpttrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpttrf(armpl_int_t n, float *d,
                           armpl_singlecomplex_t *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrf*, *LAPACKE_dpttrf*, *LAPACKE_spttrf* and *LAPACKE_zpttrf*. It also exists with a native Fortran interface as *cpttrf*.

4.19.439 LAPACKE_cpttrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpttrf_work(armpl_int_t n, float *d,
                                armpl_singlecomplex_t *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrf_work*, *LAPACKE_dpttrf_work*, *LAPACKE_spttrf_work* and *LAPACKE_zpttrf_work*.

4.19.440 LAPACKE_cpttrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpttrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *d,
                           const armpl_singlecomplex_t *e,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrs*, *LAPACKE_dpttrs*, *LAPACKE_spttrs* and *LAPACKE_zpttrs*. It also exists with a native Fortran interface as *cpttrs*.

4.19.441 LAPACKE_cpttrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cpttrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *d,
                                const armpl_singlecomplex_t *e,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrs_work*, *LAPACKE_dpttrs_work*, *LAPACKE_spttrs_work* and *LAPACKE_zpttrs_work*.

4.19.442 LAPACKE_cspcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cspcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *ap,
                           const armpl_int_t *ipiv, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspcon*, *LAPACKE_dspcon*, *LAPACKE_sspcon* and *LAPACKE_zspcon*. It also exists with a native Fortran interface as *cspcon*.

4.19.443 LAPACKE_cspcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cspcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_singlecomplex_t *ap,
                                const armpl_int_t *ipiv, float anorm,
                                float *rcond, armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspcon_work*, *LAPACKE_dspcon_work*, *LAPACKE_sspcon_work* and *LAPACKE_zspcon_work*.

4.19.444 LAPACKE_csprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           const armpl_singlecomplex_t *afp,
                           const armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csprfs*, *LAPACKE_dsprfs*, *LAPACKE_ssprfs* and *LAPACKE_zsprfs*. It also exists with a native Fortran interface as *csprfs*.

4.19.445 LAPACKE_csprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                const armpl_singlecomplex_t *afp,
                                const armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.446 LAPACKE_cspsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cspsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_singlecomplex_t *ap,
                          armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsv*, *LAPACKE_dspsv*, *LAPACKE_sspsv* and *LAPACKE_zspsv*. It also exists with a native Fortran interface as *cspsv*.

4.19.447 LAPACKE_cspsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cspsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_singlecomplex_t *ap, armpl_int_t *ipiv,
                               armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsv_work*, *LAPACKE_dspsv_work*, *LAPACKE_sspsv_work* and *LAPACKE_zspsv_work*.

4.19.448 LAPACKE_cspsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cspsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           armpl_singlecomplex_t *afp, armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.449 LAPACKE_cspsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cspsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                armpl_singlecomplex_t *afp, armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsvx_work*, *LAPACKE_dspsvx_work*, *LAPACKE_sspsvx_work* and *LAPACKE_zspsvx_work*.

4.19.450 LAPACKE_csptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *ap,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrf*, *LAPACKE_dsptrf*, *LAPACKE_ssptrf* and *LAPACKE_zsptrf*. It also exists with a native Fortran interface as *csptrf*.

4.19.451 LAPACKE_csptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *ap,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrf_work*, *LAPACKE_dsptrf_work*, *LAPACKE_ssptrf_work* and *LAPACKE_zsptrf_work*.

4.19.452 LAPACKE_csptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *ap,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptri*, *LAPACKE_dsptri*, *LAPACKE_ssptri* and *LAPACKE_zsptri*. It also exists with a native Fortran interface as *csptri*.

4.19.453 LAPACKE_csptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *ap,
                                const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptri_work*, *LAPACKE_dsptri_work*, *LAPACKE_ssptri_work* and *LAPACKE_zsptri_work*.

4.19.454 LAPACKE_csptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrs*, *LAPACKE_dsptrs*, *LAPACKE_ssptrs* and *LAPACKE_zsptrs*. It also exists with a native Fortran interface as *csptrs*.

4.19.455 LAPACKE_csptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrs_work*, *LAPACKE_dsptrs_work*, *LAPACKE_ssptrs_work* and *LAPACKE_zsptrs_work*.

4.19.456 LAPACKE_cstedc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cstedc(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, float *d, float *e,
                           armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstedc*, *LAPACKE_dstedc*, *LAPACKE_sstedc* and *LAPACKE_zstedc*. It also exists with a native Fortran interface as *cstedc*.

4.19.457 LAPACKE_cstedc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cstedc_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, float *d, float *e,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstedc_work*, *LAPACKE_dstedc_work*, *LAPACKE_sstedc_work* and *LAPACKE_zstedc_work*.

4.19.458 LAPACKE_cstegr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cstegr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, float *d, float *e, float vl,
                           float vu, armpl_int_t il, armpl_int_t iu,
                           float abstol, armpl_int_t *m, float *w,
                           armpl_singlecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstegr*, *LAPACKE_dstegr*, *LAPACKE_sstegr* and *LAPACKE_zstegr*. It also exists with a native Fortran interface as *cstegr*.

4.19.459 LAPACKE_cstegr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cstegr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, float *d, float *e,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, float abstol, armpl_int_t *m,
                                float *w, armpl_singlecomplex_t *z,
                                armpl_int_t ldz, armpl_int_t *isuppz,
                                float *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstegr_work*, *LAPACKE_dstegr_work*, *LAPACKE_sstegr_work* and *LAPACKE_zstegr_work*.

4.19.460 LAPACKE_cstein

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cstein(armpl_int_t matrix_layout, armpl_int_t n,
                           const float *d, const float *e, armpl_int_t m,
                           const float *w, const armpl_int_t *iblock,
                           const armpl_int_t *isplit,
                           armpl_singlecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *ifailv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstein*, *LAPACKE_dstein*, *LAPACKE_sstein* and *LAPACKE_zstein*. It also exists with a native Fortran interface as *cstein*.

4.19.461 LAPACKE_cstein_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cstein_work(armpl_int_t matrix_layout, armpl_int_t n,
                                const float *d, const float *e, armpl_int_t m,
                                const float *w, const armpl_int_t *iblock,
                                const armpl_int_t *isplit,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                float *work, armpl_int_t *iwork,
                                armpl_int_t *ifailv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstein_work*, *LAPACKE_dstein_work*, *LAPACKE_sstein_work* and *LAPACKE_zstein_work*.

4.19.462 LAPACKE_cstemr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cstemr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, float *d, float *e, float vl,
                           float vu, armpl_int_t il, armpl_int_t iu,
                           armpl_int_t *m, float *w, armpl_singlecomplex_t *z,
                           armpl_int_t ldz, armpl_int_t nzc,
                           armpl_int_t *isuppz, armpl_int_t *tryrac);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstemr*, *LAPACKE_dstemr*, *LAPACKE_sstemr* and *LAPACKE_zstemr*. It also exists with a native Fortran interface as *cstemr*.

4.19.463 LAPACKE_cstemr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cstemr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, float *d, float *e,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, armpl_int_t *m, float *w,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_int_t nzc, armpl_int_t *isuppz,
                                armpl_int_t *tryrac, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.464 LAPACKE_csteqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csteqr(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, float *d, float *e,
                           armpl_singlecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csteqr*, *LAPACKE_dsteqr*, *LAPACKE_ssteqr* and *LAPACKE_zsteqr*. It also exists with a native Fortran interface as *csteqr*.

4.19.465 LAPACKE_csteqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csteqr_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, float *d, float *e,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csteqr_work*, *LAPACKE_dsteqr_work*, *LAPACKE_ssteqr_work* and *LAPACKE_zsteqr_work*.

4.19.466 LAPACKE_csycon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csycon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, const armpl_int_t *ipiv,
                           float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon*, *LAPACKE_dsycon*, *LAPACKE_ssycon* and *LAPACKE_zsycon*. It also exists with a native Fortran interface as *csycon*.

4.19.467 LAPACKE_csycon_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csycon_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, const armpl_singlecomplex_t *a,
                             armpl_int_t lda, const armpl_singlecomplex_t *e,
                             const armpl_int_t *ipiv, float anorm,
                             float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_3*, *LAPACKE_dsycon_3*, *LAPACKE_ssycon_3* and *LAPACKE_zsycon_3*. It also exists with a native Fortran interface as *csycon_3*.

4.19.468 LAPACKE_csycon_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csycon_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n,
                                  const armpl_singlecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_singlecomplex_t *e,
                                  const armpl_int_t *ipiv, float anorm,
                                  float *rcond, armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_3_work*, *LAPACKE_dsycon_3_work*, *LAPACKE_ssycon_3_work* and *LAPACKE_zsycon_3_work*.

4.19.469 LAPACKE_csycon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csycon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                float anorm, float *rcond,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_work*, *LAPACKE_dsycon_work*, *LAPACKE_ssycon_work* and *LAPACKE_zsycon_work*.

4.19.470 LAPACKE_csyconv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyconv(armpl_int_t matrix_layout, char uplo, char way,
                            armpl_int_t n, armpl_singlecomplex_t *a,
                            armpl_int_t lda, const armpl_int_t *ipiv,
                            armpl_singlecomplex_t *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyconv*, *LAPACKE_dsyconv*, *LAPACKE_ssyconv* and *LAPACKE_zsyconv*. It also exists with a native Fortran interface as *csyconv*.

4.19.471 LAPACKE_csyconv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyconv_work(armpl_int_t matrix_layout, char uplo,
                                 char way, armpl_int_t n,
                                 armpl_singlecomplex_t *a, armpl_int_t lda,
                                 const armpl_int_t *ipiv,
                                 armpl_singlecomplex_t *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyconv_work*, *LAPACKE_dsyconv_work*, *LAPACKE_ssyconv_work* and *LAPACKE_zsyconv_work*.

4.19.472 LAPACKE_csyequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyequb(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, const armpl_singlecomplex_t *a,
                            armpl_int_t lda, float *s, float *scond,
                            float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyequb*, *LAPACKE_dsyequb*, *LAPACKE_ssyequb* and *LAPACKE_zsyequb*. It also exists with a native Fortran interface as *csyequb*.

4.19.473 LAPACKE_csyequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyequb_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n,
                                 const armpl_singlecomplex_t *a,
                                 armpl_int_t lda, float *s, float *scond,
                                 float *amax, armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyequb_work*, *LAPACKE_dsyequb_work*, *LAPACKE_ssyequb_work* and *LAPACKE_zsyequb_work*.

4.19.474 LAPACKE_csyr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyr(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                         armpl_singlecomplex_t alpha,
                         const armpl_singlecomplex_t *x, armpl_int_t incx,
                         armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyr* and *LAPACKE_zsyr*. It also exists with a native Fortran interface as *csyr*.

4.19.475 LAPACKE_csyr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyr_work(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_singlecomplex_t alpha,
                              const armpl_singlecomplex_t *x,
                              armpl_int_t incx, armpl_singlecomplex_t *a,
                              armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyr_work* and *LAPACKE_zsyr_work*.

4.19.476 LAPACKE_csyrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *af, armpl_int_t ldaf,
                           const armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyrfs*, *LAPACKE_dsyrfs*, *LAPACKE_ssyrfs* and *LAPACKE_zsyrfs*. It also exists with a native Fortran interface as *csyrfs*.

4.19.477 LAPACKE_csyrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
```

(continues on next page)

(continued from previous page)

```
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *af,
                                armpl_int_t ldaf, const armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyrfs_work*, *LAPACKE_dsyrfs_work*, *LAPACKE_ssyrfs_work* and *LAPACKE_zsyrfs_work*.

4.19.478 LAPACKE_csyrfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyrfsx(armpl_int_t matrix_layout, char uplo, char equed,
                            armpl_int_t n, armpl_int_t nrhs,
                            const armpl_singlecomplex_t *a, armpl_int_t lda,
                            const armpl_singlecomplex_t *af, armpl_int_t ldaf,
                            const armpl_int_t *ipiv, const float *s,
                            const armpl_singlecomplex_t *b, armpl_int_t ldb,
                            armpl_singlecomplex_t *x, armpl_int_t ldx,
                            float *rcond, float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyrfsx*, *LAPACKE_dsyrfsx*, *LAPACKE_ssyrfsx* and *LAPACKE_zsyrfsx*. It also exists with a native Fortran interface as *csyrfsx*.

4.19.479 LAPACKE_csyrfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyrfsx_work(armpl_int_t matrix_layout, char uplo,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const armpl_singlecomplex_t *a,
                                 armpl_int_t lda,
                                 const armpl_singlecomplex_t *af,
                                 armpl_int_t ldaf, const armpl_int_t *ipiv,
                                 const float *s,
                                 const armpl_singlecomplex_t *b,
                                 armpl_int_t ldb, armpl_singlecomplex_t *x,
                                 armpl_int_t ldx, float *rcond, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, armpl_singlecomplex_t *work,
                                 float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyrfsx_work*, *LAPACKE_dsyrfsx_work*, *LAPACKE_ssyrfsx_work* and *LAPACKE_zsyrfsx_work*.

4.19.480 LAPACKE_csysv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_singlecomplex_t *a,
                          armpl_int_t lda, armpl_int_t *ipiv,
                          armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv*, *LAPACKE_dsysv*, *LAPACKE_ssysv* and *LAPACKE_zsysv*. It also exists with a native Fortran interface as *csysv*.

4.19.481 LAPACKE_csysv_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysv_aa(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             armpl_singlecomplex_t *a, armpl_int_t lda,
                             armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                             armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_aa*, *LAPACKE_dsysv_aa*, *LAPACKE_ssysv_aa* and *LAPACKE_zsysv_aa*. It also exists with a native Fortran interface as *csysv_aa*.

4.19.482 LAPACKE_csysv_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysv_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs,
                                    armpl_singlecomplex_t *a, armpl_int_t lda,
                                    armpl_singlecomplex_t *tb,
```

(continues on next page)

(continued from previous page)

```
                                    armpl_int_t ltb, armpl_int_t *ipiv,
                                    armpl_int_t *ipiv2,
                                    armpl_singlecomplex_t *b,
                                    armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.483 LAPACKE_csysv_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysv_aa_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  armpl_singlecomplex_t *a, armpl_int_t lda,
                                  armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                                  armpl_int_t ldb,
                                  armpl_singlecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_aa_work*, *LAPACKE_dsysv_aa_work*, *LAPACKE_ssysv_aa_work* and *LAPACKE_zsysv_aa_work*.

4.19.484 LAPACKE_csysv_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysv_rk(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             armpl_singlecomplex_t *a, armpl_int_t lda,
                             armpl_singlecomplex_t *e, armpl_int_t *ipiv,
                             armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rk*, *LAPACKE_dsysv_rk*, *LAPACKE_ssysv_rk* and *LAPACKE_zsysv_rk*. It also exists with a native Fortran interface as *csysv_rk*.

4.19.485 LAPACKE_csysv_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysv_rk_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  armpl_singlecomplex_t *a, armpl_int_t lda,
                                  armpl_singlecomplex_t *e, armpl_int_t *ipiv,
                                  armpl_singlecomplex_t *b, armpl_int_t ldb,
                                  armpl_singlecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rk_work*, *LAPACKE_dsysv_rk_work*, *LAPACKE_ssysv_rk_work* and *LAPACKE_zsysv_rk_work*.

4.19.486 LAPACKE_csysv_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysv_rook(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rook*, *LAPACKE_dsysv_rook*, *LAPACKE_ssysv_rook* and *LAPACKE_zsysv_rook*. It also exists with a native Fortran interface as *csysv_rook*.

4.19.487 LAPACKE_csysv_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysv_rook_work(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs,
                                    armpl_singlecomplex_t *a, armpl_int_t lda,
                                    armpl_int_t *ipiv,
                                    armpl_singlecomplex_t *b, armpl_int_t ldb,
                                    armpl_singlecomplex_t *work,
                                    armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rook_work*, *LAPACKE_dsysv_rook_work*, *LAPACKE_ssysv_rook_work* and *LAPACKE_zsysv_rook_work*.

4.19.488 LAPACKE_csysv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                               armpl_int_t ldb, armpl_singlecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_work*, *LAPACKE_dsysv_work*, *LAPACKE_ssysv_work* and *LAPACKE_zsysv_work*.

4.19.489 LAPACKE_csysvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, const armpl_singlecomplex_t *b,
                           armpl_int_t ldb, armpl_singlecomplex_t *x,
                           armpl_int_t ldx, float *rcond, float *ferr,
                           float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvx*, *LAPACKE_dsysvx*, *LAPACKE_ssysvx* and *LAPACKE_zsysvx*. It also exists with a native Fortran interface as *csysvx*.

4.19.490 LAPACKE_csysvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *af,
                                armpl_int_t ldaf, armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvx_work*, *LAPACKE_dsysvx_work*, *LAPACKE_ssysvx_work* and *LAPACKE_zsysvx_work*.

4.19.491 LAPACKE_csysvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs,
                            armpl_singlecomplex_t *a, armpl_int_t lda,
                            armpl_singlecomplex_t *af, armpl_int_t ldaf,
                            armpl_int_t *ipiv, char *equed, float *s,
                            armpl_singlecomplex_t *b, armpl_int_t ldb,
                            armpl_singlecomplex_t *x, armpl_int_t ldx,
                            float *rcond, float *rpvgrw, float *berr,
                            armpl_int_t n_err_bnds, float *err_bnds_norm,
                            float *err_bnds_comp, armpl_int_t nparams,
                            float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvxx*, *LAPACKE_dsysvxx*, *LAPACKE_ssysvxx* and *LAPACKE_zsysvxx*. It also exists with a native Fortran interface as *csysvxx*.

4.19.492 LAPACKE_csysvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csysvxx_work(armpl_int_t matrix_layout, char fact,
                                 char uplo, armpl_int_t n, armpl_int_t nrhs,
                                 armpl_singlecomplex_t *a, armpl_int_t lda,
                                 armpl_singlecomplex_t *af, armpl_int_t ldaf,
                                 armpl_int_t *ipiv, char *equed, float *s,
                                 armpl_singlecomplex_t *b, armpl_int_t ldb,
                                 armpl_singlecomplex_t *x, armpl_int_t ldx,
                                 float *rcond, float *rpvgrw, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, armpl_singlecomplex_t *work,
                                 float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvxx_work*, *LAPACKE_dsysvxx_work*, *LAPACKE_ssysvxx_work* and *LAPACKE_zsysvxx_work*.

4.19.493 LAPACKE_csyswapr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyswapr(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_singlecomplex_t *a,
                             armpl_int_t lda, armpl_int_t i1,
                             armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyswapr*, *LAPACKE_dsyswapr*, *LAPACKE_ssyswapr* and *LAPACKE_zsyswapr*. It also exists with a native Fortran interface as *csyswapr*.

4.19.494 LAPACKE_csyswapr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csyswapr_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_singlecomplex_t *a,
                                  armpl_int_t lda, armpl_int_t i1,
                                  armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyswapr_work*, *LAPACKE_dsyswapr_work*, *LAPACKE_ssyswapr_work* and *LAPACKE_zsyswapr_work*.

4.19.495 LAPACKE_csytrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf*, *LAPACKE_dsytrf*, *LAPACKE_ssytrf* and *LAPACKE_zsytrf*. It also exists with a native Fortran interface as *csytrf*.

4.19.496 LAPACKE_csytrf_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrf_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_singlecomplex_t *a,
                              armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa*, *LAPACKE_dsytrf_aa*, *LAPACKE_ssytrf_aa* and *LAPACKE_zsytrf_aa*. It also exists with a native Fortran interface as *csytrf_aa*.

4.19.497 LAPACKE_csytrf_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrf_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_singlecomplex_t *a,
                                     armpl_int_t lda,
                                     armpl_singlecomplex_t *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa_2stage*, *LAPACKE_dsytrf_aa_2stage*, *LAPACKE_ssytrf_aa_2stage* and *LAPACKE_zsytrf_aa_2stage*. It also exists with a native Fortran interface as *csytrf_aa_2stage*.

4.19.498 LAPACKE_csytrf_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrf_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_singlecomplex_t *a,
                                   armpl_int_t lda, armpl_int_t *ipiv,
                                   armpl_singlecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa_work*, *LAPACKE_dsytrf_aa_work*, *LAPACKE_ssytrf_aa_work* and *LAPACKE_zsytrf_aa_work*.

4.19.499 LAPACKE_csytrf_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrf_rk(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_singlecomplex_t *a,
                              armpl_int_t lda, armpl_singlecomplex_t *e,
                              armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rk*, *LAPACKE_dsytrf_rk*, *LAPACKE_ssytrf_rk* and *LAPACKE_zsytrf_rk*. It also exists with a native Fortran interface as *csytrf_rk*.

4.19.500 LAPACKE_csytrf_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrf_rk_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_singlecomplex_t *a,
                                   armpl_int_t lda, armpl_singlecomplex_t *e,
                                   armpl_int_t *ipiv,
                                   armpl_singlecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.501 LAPACKE_csytrf_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrf_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rook*, *LAPACKE_dsytrf_rook*, *LAPACKE_ssytrf_rook* and *LAPACKE_zsytrf_rook*. It also exists with a native Fortran interface as *csytrf_rook*.

4.19.502 LAPACKE_csytrf_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrf_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_singlecomplex_t *a,
                                     armpl_int_t lda, armpl_int_t *ipiv,
                                     armpl_singlecomplex_t *work,
                                     armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rook_work*, *LAPACKE_dsytrf_rook_work*, *LAPACKE_ssytrf_rook_work* and *LAPACKE_zsytrf_rook_work*.

4.19.503 LAPACKE_csytrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_work*, *LAPACKE_dsytrf_work*, *LAPACKE_ssytrf_work* and *LAPACKE_zsytrf_work*.

4.19.504 LAPACKE_csytri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri*, *LAPACKE_dsytri*, *LAPACKE_ssytri* and *LAPACKE_zsytri*. It also exists with a native Fortran interface as *csytri*.

4.19.505 LAPACKE_csytri2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytri2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_singlecomplex_t *a,
                            armpl_int_t lda, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2*, *LAPACKE_dsytri2*, *LAPACKE_ssytri2* and *LAPACKE_zsytri2*. It also exists with a native Fortran interface as *csytri2*.

4.19.506 LAPACKE_csytri2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytri2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, const armpl_int_t *ipiv,
                                 armpl_singlecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2_work*, *LAPACKE_dsytri2_work*, *LAPACKE_ssytri2_work* and *LAPACKE_zsytri2_work*.

4.19.507 LAPACKE_csytri2x

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytri2x(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_singlecomplex_t *a,
                             armpl_int_t lda, const armpl_int_t *ipiv,
                             armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2x*, *LAPACKE_dsytri2x*, *LAPACKE_ssytri2x* and *LAPACKE_zsytri2x*. It also exists with a native Fortran interface as *csytri2x*.

4.19.508 LAPACKE_csytri2x_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytri2x_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_singlecomplex_t *a,
                                  armpl_int_t lda, const armpl_int_t *ipiv,
                                  armpl_singlecomplex_t *work,
                                  armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.509 LAPACKE_csytri_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytri_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_singlecomplex_t *a,
                             armpl_int_t lda, const armpl_singlecomplex_t *e,
                             const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri_3*, *LAPACKE_dsytri_3*, *LAPACKE_ssytri_3* and *LAPACKE_zsytri_3*. It also exists with a native Fortran interface as *csytri_3*.

4.19.510 LAPACKE_csytri_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytri_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_singlecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_singlecomplex_t *e,
                                  const armpl_int_t *ipiv,
```

(continues on next page)

(continued from previous page)

```
                                    armpl_singlecomplex_t *work,
                                    armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri_3_work*, *LAPACKE_dsytri_3_work*, *LAPACKE_ssytri_3_work* and *LAPACKE_zsytri_3_work*.

4.19.511 LAPACKE_csytri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.512 LAPACKE_csytrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
```

(continues on next page)

(continued from previous page)

4.19.515 LAPACKE_csytrs_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrs_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             const armpl_singlecomplex_t *a, armpl_int_t lda,
                             const armpl_singlecomplex_t *e,
                             const armpl_int_t *ipiv,
                             armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_3*, *LAPACKE_dsytrs_3*, *LAPACKE_ssytrs_3* and *LAPACKE_zsytrs_3*. It also exists with a native Fortran interface as *csytrs_3*.

4.19.516 LAPACKE_csytrs_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrs_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  const armpl_singlecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_singlecomplex_t *e,
                                  const armpl_int_t *ipiv,
                                  armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_3_work*, *LAPACKE_dsytrs_3_work*, *LAPACKE_ssytrs_3_work* and *LAPACKE_zsytrs_3_work*.

4.19.517 LAPACKE_csytrs_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrs_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_int_t nrhs,
                              const armpl_singlecomplex_t *a, armpl_int_t lda,
                              const armpl_int_t *ipiv,
                              armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa*, *LAPACKE_dsytrs_aa*, *LAPACKE_ssytrs_aa* and *LAPACKE_zsytrs_aa*. It also exists with a native Fortran interface as *csytrs_aa*.

4.19.518 LAPACKE_csytrs_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrs_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     armpl_singlecomplex_t *a,
                                     armpl_int_t lda,
                                     armpl_singlecomplex_t *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2,
                                     armpl_singlecomplex_t *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa_2stage*, *LAPACKE_dsytrs_aa_2stage*, *LAPACKE_ssytrs_aa_2stage* and *LAPACKE_zsytrs_aa_2stage*. It also exists with a native Fortran interface as *csytrs_aa_2stage*.

4.19.519 LAPACKE_csytrs_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrs_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_int_t nrhs,
                                   const armpl_singlecomplex_t *a,
                                   armpl_int_t lda, const armpl_int_t *ipiv,
                                   armpl_singlecomplex_t *b, armpl_int_t ldb,
                                   armpl_singlecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa_work*, *LAPACKE_dsytrs_aa_work*, *LAPACKE_ssytrs_aa_work* and *LAPACKE_zsytrs_aa_work*.

4.19.520 LAPACKE_csytrs_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrs_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_rook*, *LAPACKE_dsytrs_rook*, *LAPACKE_ssytrs_rook* and *LAPACKE_zsytrs_rook*. It also exists with a native Fortran interface as *csytrs_rook*.

4.19.521 LAPACKE_csytrs_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrs_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     const armpl_singlecomplex_t *a,
                                     armpl_int_t lda, const armpl_int_t *ipiv,
```

(continues on next page)

(continued from previous page)

```
                                        armpl_singlecomplex_t *b,
                                        armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_rook_work*, *LAPACKE_dsytrs_rook_work*, *LAPACKE_ssytrs_rook_work* and *LAPACKE_zsytrs_rook_work*.

4.19.522 LAPACKE_csytrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_csytrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_work*, *LAPACKE_dsytrs_work*, *LAPACKE_ssytrs_work* and *LAPACKE_zsytrs_work*.

4.19.523 LAPACKE_ctbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctbcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           const armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbcon*, *LAPACKE_dtbcon*, *LAPACKE_stbcon* and *LAPACKE_ztbcon*. It also exists with a native Fortran interface as *ctbcon*.

4.19.524 LAPACKE_ctbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctbcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                armpl_int_t kd,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, float *rcond,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbcon_work*, *LAPACKE_dtbcon_work*, *LAPACKE_stbcon_work* and *LAPACKE_ztbcon_work*.

4.19.525 LAPACKE_ctbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctbrfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           armpl_int_t nrhs, const armpl_singlecomplex_t *ab,
                           armpl_int_t ldab, const armpl_singlecomplex_t *b,
                           armpl_int_t ldb, const armpl_singlecomplex_t *x,
                           armpl_int_t ldx, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbrfs*, *LAPACKE_dtbrfs*, *LAPACKE_stbrfs* and *LAPACKE_ztbrfs*. It also exists with a native Fortran interface as *ctbrfs*.

4.19.526 LAPACKE_ctbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctbrfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t kd, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb,
                                const armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbrfs_work*, *LAPACKE_dtbrfs_work*, *LAPACKE_stbrfs_work* and *LAPACKE_ztbrfs_work*.

4.19.527 LAPACKE_ctbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctbtrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           armpl_int_t nrhs, const armpl_singlecomplex_t *ab,
                           armpl_int_t ldab, armpl_singlecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbtrs*, *LAPACKE_dtbtrs*, *LAPACKE_stbtrs* and *LAPACKE_ztbtrs*. It also exists with a native Fortran interface as *ctbtrs*.

4.19.528 LAPACKE_ctbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctbtrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t kd, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, armpl_singlecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbtrs_work*, *LAPACKE_dtbtrs_work*, *LAPACKE_stbtrs_work* and *LAPACKE_ztbtrs_work*.

4.19.529 LAPACKE_ctfsm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctfsm(armpl_int_t matrix_layout, char transr, char side,
                          char uplo, char trans, char diag, armpl_int_t m,
                          armpl_int_t n, armpl_singlecomplex_t alpha,
                          const armpl_singlecomplex_t *a,
                          armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfsm*, *LAPACKE_dtfsm*, *LAPACKE_stfsm* and *LAPACKE_ztfsm*. It also exists with a native Fortran interface as *ctfsm*.

4.19.530 LAPACKE_ctfsm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctfsm_work(armpl_int_t matrix_layout, char transr,
                               char side, char uplo, char trans, char diag,
                               armpl_int_t m, armpl_int_t n,
                               armpl_singlecomplex_t alpha,
                               const armpl_singlecomplex_t *a,
                               armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfsm_work*, *LAPACKE_dtfsm_work*, *LAPACKE_stfsm_work* and *LAPACKE_ztfsm_work*.

4.19.531 LAPACKE_ctftri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctftri(armpl_int_t matrix_layout, char transr, char uplo,
                           char diag, armpl_int_t n,
                           armpl_singlecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctftri*, *LAPACKE_dtftri*, *LAPACKE_stftri* and *LAPACKE_ztftri*. It also exists with a native Fortran interface as *ctftri*.

4.19.532 LAPACKE_ctftri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctftri_work(armpl_int_t matrix_layout, char transr,
                                char uplo, char diag, armpl_int_t n,
                                armpl_singlecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctftri_work*, *LAPACKE_dtftri_work*, *LAPACKE_stftri_work* and *LAPACKE_ztftri_work*.

4.19.533 LAPACKE_ctfttp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctfttp(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *arf,
                           armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttp*, *LAPACKE_dtfttp*, *LAPACKE_stfttp* and *LAPACKE_ztfttp*. It also exists with a native Fortran interface as *ctfttp*.

4.19.534 LAPACKE_ctfttp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctfttp_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                const armpl_singlecomplex_t *arf,
                                armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.535 LAPACKE_ctfttr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctfttr(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *arf,
                           armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttr*, *LAPACKE_dtfttr*, *LAPACKE_stfttr* and *LAPACKE_ztfttr*. It also exists with a native Fortran interface as *ctfttr*.

4.19.536 LAPACKE_ctfttr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctfttr_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                const armpl_singlecomplex_t *arf,
                                armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.537 LAPACKE_ctgevc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgevc(armpl_int_t matrix_layout, char side, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const armpl_singlecomplex_t *s, armpl_int_t lds,
                           const armpl_singlecomplex_t *p, armpl_int_t ldp,
                           armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                           armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t mm, armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgevc*, *LAPACKE_dtgevc*, *LAPACKE_stgevc* and *LAPACKE_ztgevc*. It also exists with a native Fortran interface as *ctgevc*.

4.19.538 LAPACKE_ctgevc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgevc_work(armpl_int_t matrix_layout, char side,
                                char howmny, const armpl_int_t *select,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t n, const armpl_singlecomplex_t *s,
                                armpl_int_t lds,
                                const armpl_singlecomplex_t *p,
                                armpl_int_t ldp, armpl_singlecomplex_t *vl,
                                armpl_int_t ldvl, armpl_singlecomplex_t *vr,
                                armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgevc_work*, *LAPACKE_dtgevc_work*, *LAPACKE_stgevc_work* and *LAPACKE_ztgevc_work*.

4.19.539 LAPACKE_ctgexc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgexc(armpl_int_t matrix_layout, armpl_int_t wantq,
                           armpl_int_t wantz, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *q, armpl_int_t ldq,
                           armpl_singlecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t ifst, armpl_int_t ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgexc*, *LAPACKE_dtgexc*, *LAPACKE_stgexc* and *LAPACKE_ztgexc*. It also exists with a native Fortran interface as *ctgexc*.

4.19.540 LAPACKE_ctgexc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgexc_work(armpl_int_t matrix_layout, armpl_int_t wantq,
                                armpl_int_t wantz, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *q, armpl_int_t ldq,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_int_t ifst, armpl_int_t ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgexc_work*, *LAPACKE_dtgexc_work*, *LAPACKE_stgexc_work* and *LAPACKE_ztgexc_work*.

4.19.541 LAPACKE_ctgsen

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgsen(armpl_int_t matrix_layout, armpl_int_t ijob,
                           armpl_int_t wantq, armpl_int_t wantz,
                           const armpl_int_t *select, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *alpha,
                           armpl_singlecomplex_t *beta,
                           armpl_singlecomplex_t *q, armpl_int_t ldq,
                           armpl_singlecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *m, float *pl, float *pr, float *dif);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsen*, *LAPACKE_dtgsen*, *LAPACKE_stgsen* and *LAPACKE_ztgsen*. It also exists with a native Fortran interface as *ctgsen*.

4.19.542 LAPACKE_ctgsen_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgsen_work(armpl_int_t matrix_layout, armpl_int_t ijob,
                                armpl_int_t wantq, armpl_int_t wantz,
                                const armpl_int_t *select, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *alpha,
                                armpl_singlecomplex_t *beta,
                                armpl_singlecomplex_t *q, armpl_int_t ldq,
                                armpl_singlecomplex_t *z, armpl_int_t ldz,
                                armpl_int_t *m, float *pl, float *pr,
                                float *dif, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.543 LAPACKE_ctgsja

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgsja(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t p,
                           armpl_int_t n, armpl_int_t k, armpl_int_t l,
```

(continues on next page)

(continued from previous page)

```
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                float tola, float tolb, float *alpha, float *beta,
                                armpl_singlecomplex_t *u, armpl_int_t ldu,
                                armpl_singlecomplex_t *v, armpl_int_t ldv,
                                armpl_singlecomplex_t *q, armpl_int_t ldq,
                                armpl_int_t *ncycle);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsja*, *LAPACKE_dtgsja*, *LAPACKE_stgsja* and *LAPACKE_ztgsja*. It also exists with a native Fortran interface as *ctgsja*.

4.19.544 LAPACKE_ctgsja_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgsja_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n, armpl_int_t k,
                                armpl_int_t l, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, float tola, float tolb,
                                float *alpha, float *beta,
                                armpl_singlecomplex_t *u, armpl_int_t ldu,
                                armpl_singlecomplex_t *v, armpl_int_t ldv,
                                armpl_singlecomplex_t *q, armpl_int_t ldq,
                                armpl_singlecomplex_t *work,
                                armpl_int_t *ncycle);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsja_work*, *LAPACKE_dtgsja_work*, *LAPACKE_stgsja_work* and *LAPACKE_ztgsja_work*.

4.19.545 LAPACKE_ctgsna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgsna(armpl_int_t matrix_layout, char job, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           const armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                           const armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                           float *s, float *dif, armpl_int_t mm,
                           armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsna*, *LAPACKE_dtgsna*, *LAPACKE_stgsna* and *LAPACKE_ztgsna*. It also exists with a native Fortran interface as *ctgsna*.

4.19.546 LAPACKE_ctgsna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgsna_work(armpl_int_t matrix_layout, char job,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb,
                                const armpl_singlecomplex_t *vl,
                                armpl_int_t ldvl,
                                const armpl_singlecomplex_t *vr,
                                armpl_int_t ldvr, float *s, float *dif,
                                armpl_int_t mm, armpl_int_t *m,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsna_work*, *LAPACKE_dtgsna_work*, *LAPACKE_stgsna_work* and *LAPACKE_ztgsna_work*.

4.19.547 LAPACKE_ctgsyl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgsyl(armpl_int_t matrix_layout, char trans,
                           armpl_int_t ijob, armpl_int_t m, armpl_int_t n,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *c, armpl_int_t ldc,
                           const armpl_singlecomplex_t *d, armpl_int_t ldd,
                           const armpl_singlecomplex_t *e, armpl_int_t lde,
                           armpl_singlecomplex_t *f, armpl_int_t ldf,
                           float *scale, float *dif);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsyl*, *LAPACKE_dtgsyl*, *LAPACKE_stgsyl* and *LAPACKE_ztgsyl*. It also exists with a native Fortran interface as *ctgsyl*.

4.19.548 LAPACKE_ctgsyl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctgsyl_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t ijob, armpl_int_t m,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *c,
                                armpl_int_t ldc,
                                const armpl_singlecomplex_t *d,
                                armpl_int_t ldd,
                                const armpl_singlecomplex_t *e,
                                armpl_int_t lde, armpl_singlecomplex_t *f,
                                armpl_int_t ldf, float *scale, float *dif,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsyl_work*, *LAPACKE_dtgsyl_work*, *LAPACKE_stgsyl_work* and *LAPACKE_ztgsyl_work*.

4.19.549 LAPACKE_ctpcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n,
                           const armpl_singlecomplex_t *ap, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpcon*, *LAPACKE_dtpcon*, *LAPACKE_stpcon* and *LAPACKE_ztpcon*. It also exists with a native Fortran interface as *ctpcon*.

4.19.550 LAPACKE_ctpcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                const armpl_singlecomplex_t *ap, float *rcond,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpcon_work*, *LAPACKE_dtpcon_work*, *LAPACKE_stpcon_work* and *LAPACKE_ztpcon_work*.

4.19.551 LAPACKE_ctpmqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpmqrt(armpl_int_t matrix_layout, char side, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t k,
                            armpl_int_t l, armpl_int_t nb,
                            const armpl_singlecomplex_t *v, armpl_int_t ldv,
                            const armpl_singlecomplex_t *t, armpl_int_t ldt,
                            armpl_singlecomplex_t *a, armpl_int_t lda,
                            armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpmqrt*, *LAPACKE_dtpmqrt*, *LAPACKE_stpmqrt* and *LAPACKE_ztpmqrt*. It also exists with a native Fortran interface as *ctpmqrt*.

4.19.552 LAPACKE_ctpmqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpmqrt_work(armpl_int_t matrix_layout, char side,
                                 char trans, armpl_int_t m, armpl_int_t n,
                                 armpl_int_t k, armpl_int_t l, armpl_int_t nb,
                                 const armpl_singlecomplex_t *v,
                                 armpl_int_t ldv,
                                 const armpl_singlecomplex_t *t,
                                 armpl_int_t ldt, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, armpl_singlecomplex_t *b,
                                 armpl_int_t ldb,
                                 armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpmqrt_work*, *LAPACKE_dtpmqrt_work*, *LAPACKE_stpmqrt_work* and *LAPACKE_ztpmqrt_work*.

4.19.553 LAPACKE_ctpqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpqrt(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t l, armpl_int_t nb,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.554 LAPACKE_ctpqrt2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpqrt2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_int_t l,
                            armpl_singlecomplex_t *a, armpl_int_t lda,
                            armpl_singlecomplex_t *b, armpl_int_t ldb,
                            armpl_singlecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.555 LAPACKE_ctpqrt2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpqrt2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t l,
                                 armpl_singlecomplex_t *a, armpl_int_t lda,
                                 armpl_singlecomplex_t *b, armpl_int_t ldb,
                                 armpl_singlecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.556 LAPACKE_ctpqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpqrt_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t l, armpl_int_t nb,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_singlecomplex_t *t, armpl_int_t ldt,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.557 LAPACKE_ctprfb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctprfb(armpl_int_t matrix_layout, char side, char trans,
                           char direct, char storev, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, armpl_int_t l,
                           const armpl_singlecomplex_t *v, armpl_int_t ldv,
                           const armpl_singlecomplex_t *t, armpl_int_t ldt,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfb*, *LAPACKE_dtprfb*, *LAPACKE_stprfb* and *LAPACKE_ztprfb*. It also exists with a native Fortran interface as *ctprfb*.

4.19.558 LAPACKE_ctprfb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctprfb_work(armpl_int_t matrix_layout, char side,
                                char trans, char direct, char storev,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                armpl_int_t l, const armpl_singlecomplex_t *v,
                                armpl_int_t ldv,
                                const armpl_singlecomplex_t *t,
                                armpl_int_t ldt, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *work,
                                armpl_int_t ldwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfb_work*, *LAPACKE_dtprfb_work*, *LAPACKE_stprfb_work* and *LAPACKE_ztprfb_work*.

4.19.559 LAPACKE_ctprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctprfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           const armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfs*, *LAPACKE_dtprfs*, *LAPACKE_stprfs* and *LAPACKE_ztprfs*. It also exists with a native Fortran interface as *ctprfs*.

4.19.560 LAPACKE_ctprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctprfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb,
                                const armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfs_work*, *LAPACKE_dtprfs_work*, *LAPACKE_stprfs_work* and *LAPACKE_ztprfs_work*.

4.19.561 LAPACKE_ctptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctptri(armpl_int_t matrix_layout, char uplo, char diag,
                           armpl_int_t n, armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptri*, *LAPACKE_dtptri*, *LAPACKE_stptri* and *LAPACKE_ztptri*. It also exists with a native Fortran interface as *ctptri*.

4.19.562 LAPACKE_ctptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctptri_work(armpl_int_t matrix_layout, char uplo,
                                char diag, armpl_int_t n,
                                armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptri_work*, *LAPACKE_dtptri_work*, *LAPACKE_stptri_work* and *LAPACKE_ztptri_work*.

4.19.563 LAPACKE_ctptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctptrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *ap,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptrs*, *LAPACKE_dtptrs*, *LAPACKE_stptrs* and *LAPACKE_ztptrs*. It also exists with a native Fortran interface as *ctptrs*.

4.19.564 LAPACKE_ctptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctptrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ap,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptrs_work*, *LAPACKE_dtptrs_work*, *LAPACKE_stptrs_work* and *LAPACKE_ztptrs_work*.

4.19.565 LAPACKE_ctpttf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpttf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *ap,
                           armpl_singlecomplex_t *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttf*, *LAPACKE_dtpttf*, *LAPACKE_stpttf* and *LAPACKE_ztpttf*. It also exists with a native Fortran interface as *ctpttf*.

4.19.566 LAPACKE_ctpttf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpttf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                const armpl_singlecomplex_t *ap,
                                armpl_singlecomplex_t *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttf_work*, *LAPACKE_dtpttf_work*, *LAPACKE_stpttf_work* and *LAPACKE_ztpttf_work*.

4.19.567 LAPACKE_ctpttr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpttr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *ap,
                           armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttr*, *LAPACKE_dtpttr*, *LAPACKE_stpttr* and *LAPACKE_ztpttr*. It also exists with a native Fortran interface as *ctpttr*.

4.19.568 LAPACKE_ctpttr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctpttr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_singlecomplex_t *ap,
                                armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttr_work*, *LAPACKE_dtpttr_work*, *LAPACKE_stpttr_work* and *LAPACKE_ztpttr_work*.

4.19.569 LAPACKE_ctrcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrcon*, *LAPACKE_dtrcon*, *LAPACKE_strcon* and *LAPACKE_ztrcon*. It also exists with a native Fortran interface as *ctrcon*.

4.19.570 LAPACKE_ctrcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, float *rcond,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrcon_work*, *LAPACKE_dtrcon_work*, *LAPACKE_strcon_work* and *LAPACKE_ztrcon_work*.

4.19.571 LAPACKE_ctrevc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrevc(armpl_int_t matrix_layout, char side, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           armpl_singlecomplex_t *t, armpl_int_t ldt,
                           armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                           armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t mm, armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrevc*, *LAPACKE_dtrevc*, *LAPACKE_strevc* and *LAPACKE_ztrevc*. It also exists with a native Fortran interface as *ctrevc*.

4.19.572 LAPACKE_ctrevc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrevc_work(armpl_int_t matrix_layout, char side,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, armpl_singlecomplex_t *t,
                                armpl_int_t ldt, armpl_singlecomplex_t *vl,
                                armpl_int_t ldvl, armpl_singlecomplex_t *vr,
                                armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrevc_work*, *LAPACKE_dtrevc_work*, *LAPACKE_strevc_work* and *LAPACKE_ztrevc_work*.

4.19.573 LAPACKE_ctrexc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrexc(armpl_int_t matrix_layout, char compq,
                           armpl_int_t n, armpl_singlecomplex_t *t,
                           armpl_int_t ldt, armpl_singlecomplex_t *q,
                           armpl_int_t ldq, armpl_int_t ifst,
                           armpl_int_t ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrexc*, *LAPACKE_dtrexc*, *LAPACKE_strexc* and *LAPACKE_ztrexc*. It also exists with a native Fortran interface as *ctrexc*.

4.19.574 LAPACKE_ctrexc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrexc_work(armpl_int_t matrix_layout, char compq,
                                armpl_int_t n, armpl_singlecomplex_t *t,
                                armpl_int_t ldt, armpl_singlecomplex_t *q,
                                armpl_int_t ldq, armpl_int_t ifst,
                                armpl_int_t ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrexc_work*, *LAPACKE_dtrexc_work*, *LAPACKE_strexc_work* and *LAPACKE_ztrexc_work*.

4.19.575 LAPACKE_ctrrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrrfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           const armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrrfs*, *LAPACKE_dtrrfs*, *LAPACKE_strrfs* and *LAPACKE_ztrrfs*. It also exists with a native Fortran interface as *ctrrfs*.

4.19.576 LAPACKE_ctrrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrrfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs,
```

(continues on next page)

(continued from previous page)

```
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb,
                                const armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrrfs_work*, *LAPACKE_dtrrfs_work*, *LAPACKE_strrfs_work* and *LAPACKE_ztrrfs_work*.

4.19.577 LAPACKE_ctrsen

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrsen(armpl_int_t matrix_layout, char job, char compq,
                           const armpl_int_t *select, armpl_int_t n,
                           armpl_singlecomplex_t *t, armpl_int_t ldt,
                           armpl_singlecomplex_t *q, armpl_int_t ldq,
                           armpl_singlecomplex_t *w, armpl_int_t *m, float *s,
                           float *sep);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsen*, *LAPACKE_dtrsen*, *LAPACKE_strsen* and *LAPACKE_ztrsen*. It also exists with a native Fortran interface as *ctrsen*.

4.19.578 LAPACKE_ctrsen_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrsen_work(armpl_int_t matrix_layout, char job,
                                char compq, const armpl_int_t *select,
                                armpl_int_t n, armpl_singlecomplex_t *t,
                                armpl_int_t ldt, armpl_singlecomplex_t *q,
                                armpl_int_t ldq, armpl_singlecomplex_t *w,
                                armpl_int_t *m, float *s, float *sep,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsen_work*, *LAPACKE_dtrsen_work*, *LAPACKE_strsen_work* and *LAPACKE_ztrsen_work*.

4.19.579 LAPACKE_ctrsna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrsna(armpl_int_t matrix_layout, char job, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const armpl_singlecomplex_t *t, armpl_int_t ldt,
                           const armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                           const armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                           float *s, float *sep, armpl_int_t mm,
                           armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsna*, *LAPACKE_dtrsna*, *LAPACKE_strsna* and *LAPACKE_ztrsna*. It also exists with a native Fortran interface as *ctrsna*.

4.19.580 LAPACKE_ctrsna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrsna_work(armpl_int_t matrix_layout, char job,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, const armpl_singlecomplex_t *t,
                                armpl_int_t ldt,
                                const armpl_singlecomplex_t *vl,
                                armpl_int_t ldvl,
                                const armpl_singlecomplex_t *vr,
                                armpl_int_t ldvr, float *s, float *sep,
                                armpl_int_t mm, armpl_int_t *m,
                                armpl_singlecomplex_t *work,
                                armpl_int_t ldwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsna_work*, *LAPACKE_dtrsna_work*, *LAPACKE_strsna_work* and *LAPACKE_ztrsna_work*.

4.19.581 LAPACKE_ctrsyl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrsyl(armpl_int_t matrix_layout, char trana, char tranb,
                           armpl_int_t isgn, armpl_int_t m, armpl_int_t n,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *c, armpl_int_t ldc,
                           float *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsyl*, *LAPACKE_dtrsyl*, *LAPACKE_strsyl* and *LAPACKE_ztrsyl*. It also exists with a native Fortran interface as *ctrsyl*.

4.19.582 LAPACKE_ctrsyl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrsyl_work(armpl_int_t matrix_layout, char trana,
                                char tranb, armpl_int_t isgn, armpl_int_t m,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *c,
                                armpl_int_t ldc, float *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsyl_work*, *LAPACKE_dtrsyl_work*, *LAPACKE_strsyl_work* and *LAPACKE_ztrsyl_work*.

4.19.583 LAPACKE_ctrtri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrtri(armpl_int_t matrix_layout, char uplo, char diag,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtri*, *LAPACKE_dtrtri*, *LAPACKE_strtri* and *LAPACKE_ztrtri*. It also exists with a native Fortran interface as *ctrtri*.

4.19.584 LAPACKE_ctrtri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrtri_work(armpl_int_t matrix_layout, char uplo,
                                char diag, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtri_work*, *LAPACKE_dtrtri_work*, *LAPACKE_strtri_work* and *LAPACKE_ztrtri_work*.

4.19.585 LAPACKE_ctrtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrtrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtrs*, *LAPACKE_dtrtrs*, *LAPACKE_strtrs* and *LAPACKE_ztrtrs*. It also exists with a native Fortran interface as *ctrtrs*.

4.19.586 LAPACKE_ctrtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrtrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtrs_work*, *LAPACKE_dtrtrs_work*, *LAPACKE_strtrs_work* and *LAPACKE_ztrtrs_work*.

4.19.587 LAPACKE_ctrttf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrttf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttf*, *LAPACKE_dtrttf*, *LAPACKE_strttf* and *LAPACKE_ztrttf*. It also exists with a native Fortran interface as *ctrttf*.

4.19.588 LAPACKE_ctrttf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrttf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttf_work*, *LAPACKE_dtrttf_work*, *LAPACKE_strttf_work* and *LAPACKE_ztrttf_work*.

4.19.589 LAPACKE_ctrttp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrttp(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttp*, *LAPACKE_dtrttp*, *LAPACKE_strttp* and *LAPACKE_ztrttp*. It also exists with a native Fortran interface as *ctrttp*.

4.19.590 LAPACKE_ctrttp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctrttp_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttp_work*, *LAPACKE_dtrttp_work*, *LAPACKE_strttp_work* and *LAPACKE_ztrttp_work*.

4.19.591 LAPACKE_ctzrzf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctzrzf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctzrzf*, *LAPACKE_dtzrzf*, *LAPACKE_stzrzf* and *LAPACKE_ztzrzf*. It also exists with a native Fortran interface as *ctzrzf*.

4.19.592 LAPACKE_ctzrzf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ctzrzf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctzrzf_work*, *LAPACKE_dtzrzf_work*, *LAPACKE_stzrzf_work* and *LAPACKE_ztzrzf_work*.

4.19.593 LAPACKE_cunbdb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunbdb(armpl_int_t matrix_layout, char trans, char signs,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           armpl_singlecomplex_t *x11, armpl_int_t ldx11,
                           armpl_singlecomplex_t *x12, armpl_int_t ldx12,
```

(continues on next page)

(continued from previous page)

```
                                armpl_singlecomplex_t *x21, armpl_int_t ldx21,
                                armpl_singlecomplex_t *x22, armpl_int_t ldx22,
                                float *theta, float *phi,
                                armpl_singlecomplex_t *taup1,
                                armpl_singlecomplex_t *taup2,
                                armpl_singlecomplex_t *tauq1,
                                armpl_singlecomplex_t *tauq2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunbdb* and *LAPACKE_zunbdb*. It also exists with a native Fortran interface as *cunbdb*.

4.19.594 LAPACKE_cunbdb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunbdb_work(armpl_int_t matrix_layout, char trans,
                                char signs, armpl_int_t m, armpl_int_t p,
                                armpl_int_t q, armpl_singlecomplex_t *x11,
                                armpl_int_t ldx11, armpl_singlecomplex_t *x12,
                                armpl_int_t ldx12, armpl_singlecomplex_t *x21,
                                armpl_int_t ldx21, armpl_singlecomplex_t *x22,
                                armpl_int_t ldx22, float *theta, float *phi,
                                armpl_singlecomplex_t *taup1,
                                armpl_singlecomplex_t *taup2,
                                armpl_singlecomplex_t *tauq1,
                                armpl_singlecomplex_t *tauq2,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunbdb_work* and *LAPACKE_zunbdb_work*.

4.19.595 LAPACKE_cuncsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cuncsd(armpl_int_t matrix_layout, char jobu1, char jobu2,
                           char jobv1t, char jobv2t, char trans, char signs,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           armpl_singlecomplex_t *x11, armpl_int_t ldx11,
                           armpl_singlecomplex_t *x12, armpl_int_t ldx12,
                           armpl_singlecomplex_t *x21, armpl_int_t ldx21,
                           armpl_singlecomplex_t *x22, armpl_int_t ldx22,
                           float *theta, armpl_singlecomplex_t *u1,
                           armpl_int_t ldu1, armpl_singlecomplex_t *u2,
                           armpl_int_t ldu2, armpl_singlecomplex_t *v1t,
                           armpl_int_t ldv1t, armpl_singlecomplex_t *v2t,
                           armpl_int_t ldv2t);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cuncsd* and *LAPACKE_zuncsd*. It also exists with a native Fortran interface as *cuncsd*.

4.19.596 LAPACKE_cuncsd2by1

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cuncsd2by1(armpl_int_t matrix_layout, char jobu1,
                               char jobu2, char jobv1t, armpl_int_t m,
                               armpl_int_t p, armpl_int_t q,
                               armpl_singlecomplex_t *x11, armpl_int_t ldx11,
                               armpl_singlecomplex_t *x21, armpl_int_t ldx21,
                               float *theta, armpl_singlecomplex_t *u1,
                               armpl_int_t ldu1, armpl_singlecomplex_t *u2,
                               armpl_int_t ldu2, armpl_singlecomplex_t *v1t,
                               armpl_int_t ldv1t);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

                                armpl_singlecomplex_t *x12, armpl_int_t ldx12,
                                armpl_singlecomplex_t *x21, armpl_int_t ldx21,
                                armpl_singlecomplex_t *x22, armpl_int_t ldx22,
                                float *theta, armpl_singlecomplex_t *u1,
                                armpl_int_t ldu1, armpl_singlecomplex_t *u2,
                                armpl_int_t ldu2, armpl_singlecomplex_t *v1t,
                                armpl_int_t ldv1t, armpl_singlecomplex_t *v2t,
                                armpl_int_t ldv2t,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cuncsd_work* and *LAPACKE_zuncsd_work*.

4.19.599 LAPACKE_cungbr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungbr(armpl_int_t matrix_layout, char vect,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungbr* and *LAPACKE_zungbr*. It also exists with a native Fortran interface as *cungbr*.

4.19.600 LAPACKE_cungbr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungbr_work(armpl_int_t matrix_layout, char vect,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungbr_work* and *LAPACKE_zungbr_work*.

4.19.601 LAPACKE_cunghr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunghr(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t ilo, armpl_int_t ihi,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunghr* and *LAPACKE_zunghr*. It also exists with a native Fortran interface as *cunghr*.

4.19.602 LAPACKE_cunghr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunghr_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunghr_work* and *LAPACKE_zunghr_work*.

4.19.603 LAPACKE_cunglq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunglq(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunglq* and *LAPACKE_zunglq*. It also exists with a native Fortran interface as *cunglq*.

4.19.604 LAPACKE_cunglq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunglq_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunglq_work* and *LAPACKE_zunglq_work*.

4.19.605 LAPACKE_cungql

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungql(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungql* and *LAPACKE_zungql*. It also exists with a native Fortran interface as *cungql*.

4.19.606 LAPACKE_cungql_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungql_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungql_work* and *LAPACKE_zungql_work*.

4.19.607 LAPACKE_cungqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungqr(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungqr* and *LAPACKE_zungqr*. It also exists with a native Fortran interface as *cungqr*.

4.19.608 LAPACKE_cungqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungqr_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungqr_work* and *LAPACKE_zungqr_work*.

4.19.609 LAPACKE_cungrq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungrq(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungrq* and *LAPACKE_zungrq*. It also exists with a native Fortran interface as *cungrq*.

4.19.610 LAPACKE_cungrq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungrq_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungrq_work* and *LAPACKE_zungrq_work*.

4.19.611 LAPACKE_cungtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungtr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda,
                           const armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungtr* and *LAPACKE_zungtr*. It also exists with a native Fortran interface as *cungtr*.

4.19.612 LAPACKE_cungtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cungtr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungtr_work* and *LAPACKE_zungtr_work*.

4.19.613 LAPACKE_cunmbr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmbr(armpl_int_t matrix_layout, char vect, char side,
                           char trans, armpl_int_t m, armpl_int_t n,
                           armpl_int_t k, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, const armpl_singlecomplex_t *tau,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmbr* and *LAPACKE_zunmbr*. It also exists with a native Fortran interface as *cunmbr*.

4.19.614 LAPACKE_cunmbr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmbr_work(armpl_int_t matrix_layout, char vect,
                                char side, char trans, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *c, armpl_int_t ldc,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmbr_work* and *LAPACKE_zunmbr_work*.

4.19.615 LAPACKE_cunmhr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmhr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t ilo,
                           armpl_int_t ihi, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, const armpl_singlecomplex_t *tau,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmhr* and *LAPACKE_zunmhr*. It also exists with a native Fortran interface as *cunmhr*.

4.19.616 LAPACKE_cunmhr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmhr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *c, armpl_int_t ldc,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmhr_work* and *LAPACKE_zunmhr_work*.

4.19.617 LAPACKE_cunmlq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmlq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmlq* and *LAPACKE_zunmlq*. It also exists with a native Fortran interface as *cunmlq*.

4.19.618 LAPACKE_cunmlq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmlq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *c, armpl_int_t ldc,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmlq_work* and *LAPACKE_zunmlq_work*.

4.19.619 LAPACKE_cunmql

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmql(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmql* and *LAPACKE_zunmql*. It also exists with a native Fortran interface as *cunmql*.

4.19.620 LAPACKE_cunmql_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmql_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *c, armpl_int_t ldc,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmql_work* and *LAPACKE_zunmql_work*.

4.19.621 LAPACKE_cunmqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmqr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmqr* and *LAPACKE_zunmqr*. It also exists with a native Fortran interface as *cunmqr*.

4.19.622 LAPACKE_cunmqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmqr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *c, armpl_int_t ldc,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmqr_work* and *LAPACKE_zunmqr_work*.

4.19.623 LAPACKE_cunmrq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmrq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmrq* and *LAPACKE_zunmrq*. It also exists with a native Fortran interface as *cunmrq*.

4.19.624 LAPACKE_cunmrq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmrq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
```

(continues on next page)

(continued from previous page)

```
                                armpl_singlecomplex_t *c, armpl_int_t ldc,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmrq_work* and *LAPACKE_zunmrq_work*.

4.19.625 LAPACKE_cunmrz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmrz(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           armpl_int_t l, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, const armpl_singlecomplex_t *tau,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmrz* and *LAPACKE_zunmrz*. It also exists with a native Fortran interface as *cunmrz*.

4.19.626 LAPACKE_cunmrz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmrz_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, armpl_int_t l,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *c, armpl_int_t ldc,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmrz_work* and *LAPACKE_zunmrz_work*.

4.19.627 LAPACKE_cunmtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmtr(armpl_int_t matrix_layout, char side, char uplo,
                           char trans, armpl_int_t m, armpl_int_t n,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *tau,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmtr* and *LAPACKE_zunmtr*. It also exists with a native Fortran interface as *cunmtr*.

4.19.628 LAPACKE_cunmtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cunmtr_work(armpl_int_t matrix_layout, char side,
                                char uplo, char trans, armpl_int_t m,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *c, armpl_int_t ldc,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.629 LAPACKE_cupgtr

4.19.630 LAPACKE_cupgtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cupgtr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_singlecomplex_t *ap,
                                const armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *q, armpl_int_t ldq,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

```
                                    double *b12d, double *b12e, double *b21d,
                                    double *b21e, double *b22d, double *b22e,
                                    double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbbcsd_work*, *LAPACKE_dbbcsd_work*, *LAPACKE_sbbcsd_work* and *LAPACKE_zbbcsd_work*.

4.19.635 LAPACKE_dbdsdc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dbdsdc(armpl_int_t matrix_layout, char uplo, char compq,
                           armpl_int_t n, double *d, double *e, double *u,
                           armpl_int_t ldu, double *vt, armpl_int_t ldvt,
                           double *q, armpl_int_t *iq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dbdsdc* and *LAPACKE_sbdsdc*. It also exists with a native Fortran interface as *dbdsdc*.

4.19.636 LAPACKE_dbdsdc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dbdsdc_work(armpl_int_t matrix_layout, char uplo,
                                char compq, armpl_int_t n, double *d,
                                double *e, double *u, armpl_int_t ldu,
                                double *vt, armpl_int_t ldvt, double *q,
                                armpl_int_t *iq, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dbdsdc_work* and *LAPACKE_sbdsdc_work*.

4.19.637 LAPACKE_dbdsqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dbdsqr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t ncvt, armpl_int_t nru,
                           armpl_int_t ncc, double *d, double *e, double *vt,
                           armpl_int_t ldvt, double *u, armpl_int_t ldu,
                           double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbdsqr*, *LAPACKE_dbdsqr*, *LAPACKE_sbdsqr* and *LAPACKE_zbdsqr*. It also exists with a native Fortran interface as *dbdsqr*.

4.19.638 LAPACKE_dbdsqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dbdsqr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t ncvt,
                                armpl_int_t nru, armpl_int_t ncc, double *d,
                                double *e, double *vt, armpl_int_t ldvt,
                                double *u, armpl_int_t ldu, double *c,
                                armpl_int_t ldc, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbdsqr_work*, *LAPACKE_dbdsqr_work*, *LAPACKE_sbdsqr_work* and *LAPACKE_zbdsqr_work*.

4.19.639 LAPACKE_dbdsvdx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dbdsvdx(armpl_int_t matrix_layout, char uplo, char jobz,
                            char range, armpl_int_t n, double *d, double *e,
                            double vl, double vu, armpl_int_t il,
                            armpl_int_t iu, armpl_int_t *ns, double *s,
                            double *z, armpl_int_t ldz, armpl_int_t *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dbdsvdx* and *LAPACKE_sbdsvdx*. It also exists with a native Fortran interface as *dbdsvdx*.

4.19.640 LAPACKE_dbdsvdx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dbdsvdx_work(armpl_int_t matrix_layout, char uplo,
                                 char jobz, char range, armpl_int_t n,
                                 double *d, double *e, double vl, double vu,
                                 armpl_int_t il, armpl_int_t iu,
                                 armpl_int_t *ns, double *s, double *z,
                                 armpl_int_t ldz, double *work,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dbdsvdx_work* and *LAPACKE_sbdsvdx_work*.

4.19.641 LAPACKE_ddisna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ddisna(char job, armpl_int_t m, armpl_int_t n,
                           const double *d, double *sep);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ddisna* and *LAPACKE_sdisna*. It also exists with a native Fortran interface as *ddisna*.

4.19.642 LAPACKE_ddisna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ddisna_work(char job, armpl_int_t m, armpl_int_t n,
                                const double *d, double *sep);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ddisna_work* and *LAPACKE_sdisna_work*.

4.19.643 LAPACKE_dgbbrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbbrd(armpl_int_t matrix_layout, char vect,
                           armpl_int_t m, armpl_int_t n, armpl_int_t ncc,
                           armpl_int_t kl, armpl_int_t ku, double *ab,
                           armpl_int_t ldab, double *d, double *e, double *q,
                           armpl_int_t ldq, double *pt, armpl_int_t ldpt,
                           double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbbrd*, *LAPACKE_dgbbrd*, *LAPACKE_sgbbrd* and *LAPACKE_zgbbrd*. It also exists with a native Fortran interface as *dgbbrd*.

4.19.644 LAPACKE_dgbbrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbbrd_work(armpl_int_t matrix_layout, char vect,
                                armpl_int_t m, armpl_int_t n, armpl_int_t ncc,
                                armpl_int_t kl, armpl_int_t ku, double *ab,
                                armpl_int_t ldab, double *d, double *e,
                                double *q, armpl_int_t ldq, double *pt,
                                armpl_int_t ldpt, double *c, armpl_int_t ldc,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbbrd_work*, *LAPACKE_dgbbrd_work*, *LAPACKE_sgbbrd_work* and *LAPACKE_zgbbrd_work*.

4.19.645 LAPACKE_dgbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbcon(armpl_int_t matrix_layout, char norm,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           const double *ab, armpl_int_t ldab,
                           const armpl_int_t *ipiv, double anorm,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbcon*, *LAPACKE_dgbcon*, *LAPACKE_sgbcon* and *LAPACKE_zgbcon*. It also exists with a native Fortran interface as *dgbcon*.

4.19.646 LAPACKE_dgbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbcon_work(armpl_int_t matrix_layout, char norm,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                const double *ab, armpl_int_t ldab,
                                const armpl_int_t *ipiv, double anorm,
                                double *rcond, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbcon_work*, *LAPACKE_dgbcon_work*, *LAPACKE_sgbcon_work* and *LAPACKE_zgbcon_work*.

4.19.647 LAPACKE_dgbequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbequ(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           const double *ab, armpl_int_t ldab, double *r,
                           double *c, double *rowcnd, double *colcnd,
                           double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequ*, *LAPACKE_dgbequ*, *LAPACKE_sgbequ* and *LAPACKE_zgbequ*. It also exists with a native Fortran interface as *dgbequ*.

4.19.648 LAPACKE_dgbequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbequ_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                const double *ab, armpl_int_t ldab, double *r,
                                double *c, double *rowcnd, double *colcnd,
                                double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequ_work*, *LAPACKE_dgbequ_work*, *LAPACKE_sgbequ_work* and *LAPACKE_zgbequ_work*.

4.19.649 LAPACKE_dgbequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbequb(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            const double *ab, armpl_int_t ldab, double *r,
                            double *c, double *rowcnd, double *colcnd,
                            double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequb*, *LAPACKE_dgbequb*, *LAPACKE_sgbequb* and *LAPACKE_zgbequb*. It also exists with a native Fortran interface as *dgbequb*.

4.19.650 LAPACKE_dgbequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbequb_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku, const double *ab,
                                 armpl_int_t ldab, double *r, double *c,
                                 double *rowcnd, double *colcnd,
                                 double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequb_work*, *LAPACKE_dgbequb_work*, *LAPACKE_sgbequb_work* and *LAPACKE_zgbequb_work*.

4.19.651 LAPACKE_dgbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbrfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, const double *ab,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldab, const double *afb,
                                armpl_int_t ldafb, const armpl_int_t *ipiv,
                                const double *b, armpl_int_t ldb, double *x,
                                armpl_int_t ldx, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbrfs*, *LAPACKE_dgbrfs*, *LAPACKE_sgbrfs* and *LAPACKE_zgbrfs*. It also exists with a native Fortran interface as *dgbrfs*.

4.19.652 LAPACKE_dgbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbrfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                armpl_int_t nrhs, const double *ab,
                                armpl_int_t ldab, const double *afb,
                                armpl_int_t ldafb, const armpl_int_t *ipiv,
                                const double *b, armpl_int_t ldb, double *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.653 LAPACKE_dgbrfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbrfsx(armpl_int_t matrix_layout, char trans, char equed,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            armpl_int_t nrhs, const double *ab,
                            armpl_int_t ldab, const double *afb,
                            armpl_int_t ldafb, const armpl_int_t *ipiv,
                            const double *r, const double *c, const double *b,
                            armpl_int_t ldb, double *x, armpl_int_t ldx,
                            double *rcond, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbrfsx*, *LAPACKE_dgbrfsx*, *LAPACKE_sgbrfsx* and *LAPACKE_zgbrfsx*. It also exists with a native Fortran interface as *dgbrfsx*.

4.19.654 LAPACKE_dgbrfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbrfsx_work(armpl_int_t matrix_layout, char trans,
                                 char equed, armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku, armpl_int_t nrhs,
                                 const double *ab, armpl_int_t ldab,
                                 const double *afb, armpl_int_t ldafb,
                                 const armpl_int_t *ipiv, const double *r,
                                 const double *c, const double *b,
                                 armpl_int_t ldb, double *x, armpl_int_t ldx,
                                 double *rcond, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.655 LAPACKE_dgbsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t kl, armpl_int_t ku, armpl_int_t nrhs,
                          double *ab, armpl_int_t ldab, armpl_int_t *ipiv,
                          double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsv*, *LAPACKE_dgbsv*, *LAPACKE_sgbsv* and *LAPACKE_zgbsv*. It also exists with a native Fortran interface as *dgbsv*.

4.19.656 LAPACKE_dgbsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t kl, armpl_int_t ku,
                               armpl_int_t nrhs, double *ab, armpl_int_t ldab,
                               armpl_int_t *ipiv, double *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsv_work*, *LAPACKE_dgbsv_work*, *LAPACKE_sgbsv_work* and *LAPACKE_zgbsv_work*.

4.19.657 LAPACKE_dgbsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbsvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, double *ab, armpl_int_t ldab,
                           double *afb, armpl_int_t ldafb, armpl_int_t *ipiv,
                           char *equed, double *r, double *c, double *b,
                           armpl_int_t ldb, double *x, armpl_int_t ldx,
                           double *rcond, double *ferr, double *berr,
                           double *rpivot);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvx*, *LAPACKE_dgbsvx*, *LAPACKE_sgbsvx* and *LAPACKE_zgbsvx*. It also exists with a native Fortran interface as *dgbsvx*.

4.19.658 LAPACKE_dgbsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbsvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t kl,
                                armpl_int_t ku, armpl_int_t nrhs, double *ab,
                                armpl_int_t ldab, double *afb,
                                armpl_int_t ldafb, armpl_int_t *ipiv,
                                char *equed, double *r, double *c, double *b,
                                armpl_int_t ldb, double *x, armpl_int_t ldx,
                                double *rcond, double *ferr, double *berr,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.659 LAPACKE_dgbsvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbsvxx(armpl_int_t matrix_layout, char fact, char trans,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            armpl_int_t nrhs, double *ab, armpl_int_t ldab,
                            double *afb, armpl_int_t ldafb, armpl_int_t *ipiv,
                            char *equed, double *r, double *c, double *b,
                            armpl_int_t ldb, double *x, armpl_int_t ldx,
                            double *rcond, double *rpvgrw, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvxx*, *LAPACKE_dgbsvxx*, *LAPACKE_sgbsvxx* and *LAPACKE_zgbsvxx*. It also exists with a native Fortran interface as *dgbsvxx*.

4.19.660 LAPACKE_dgbsvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbsvxx_work(armpl_int_t matrix_layout, char fact,
                                 char trans, armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku, armpl_int_t nrhs, double *ab,
                                 armpl_int_t ldab, double *afb,
                                 armpl_int_t ldafb, armpl_int_t *ipiv,
                                 char *equed, double *r, double *c, double *b,
                                 armpl_int_t ldb, double *x, armpl_int_t ldx,
                                 double *rcond, double *rpvgrw, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvxx_work*, *LAPACKE_dgbsvxx_work*, *LAPACKE_sgbsvxx_work* and *LAPACKE_zgbsvxx_work*.

4.19.661 LAPACKE_dgbtrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbtrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           double *ab, armpl_int_t ldab, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrf*, *LAPACKE_dgbtrf*, *LAPACKE_sgbtrf* and *LAPACKE_zgbtrf*. It also exists with a native Fortran interface as *dgbtrf*.

4.19.662 LAPACKE_dgbtrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbtrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                double *ab, armpl_int_t ldab,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrf_work*, *LAPACKE_dgbtrf_work*, *LAPACKE_sgbtrf_work* and *LAPACKE_zgbtrf_work*.

4.19.663 LAPACKE_dgbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbtrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, const double *ab,
                           armpl_int_t ldab, const armpl_int_t *ipiv,
                           double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrs*, *LAPACKE_dgbtrs*, *LAPACKE_sgbtrs* and *LAPACKE_zgbtrs*. It also exists with a native Fortran interface as *dgbtrs*.

4.19.664 LAPACKE_dgbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgbtrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                armpl_int_t nrhs, const double *ab,
                                armpl_int_t ldab, const armpl_int_t *ipiv,
                                double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrs_work*, *LAPACKE_dgbtrs_work*, *LAPACKE_sgbtrs_work* and *LAPACKE_zgbtrs_work*.

4.19.665 LAPACKE_dgebak

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgebak(armpl_int_t matrix_layout, char job, char side,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           const double *scale, armpl_int_t m, double *v,
                           armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebak*, *LAPACKE_dgebak*, *LAPACKE_sgebak* and *LAPACKE_zgebak*. It also exists with a native Fortran interface as *dgebak*.

4.19.666 LAPACKE_dgebak_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgebak_work(armpl_int_t matrix_layout, char job,
                                char side, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, const double *scale,
                                armpl_int_t m, double *v, armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebak_work*, *LAPACKE_dgebak_work*, *LAPACKE_sgebak_work* and *LAPACKE_zgebak_work*.

4.19.667 LAPACKE_dgebal

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgebal(armpl_int_t matrix_layout, char job, armpl_int_t n,
                           double *a, armpl_int_t lda, armpl_int_t *ilo,
                           armpl_int_t *ihi, double *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebal*, *LAPACKE_dgebal*, *LAPACKE_sgebal* and *LAPACKE_zgebal*. It also exists with a native Fortran interface as *dgebal*.

4.19.668 LAPACKE_dgebal_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgebal_work(armpl_int_t matrix_layout, char job,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                armpl_int_t *ilo, armpl_int_t *ihi,
                                double *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebal_work*, *LAPACKE_dgebal_work*, *LAPACKE_sgebal_work* and *LAPACKE_zgebal_work*.

4.19.669 LAPACKE_dgebrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgebrd(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *d, double *e, double *tauq, double *taup);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebrd*, *LAPACKE_dgebrd*, *LAPACKE_sgebrd* and *LAPACKE_zgebrd*. It also exists with a native Fortran interface as *dgebrd*.

4.19.670 LAPACKE_dgebrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgebrd_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *d, double *e, double *tauq,
                                double *taup, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebrd_work*, *LAPACKE_dgebrd_work*, *LAPACKE_sgebrd_work* and *LAPACKE_zgebrd_work*.

4.19.671 LAPACKE_dgecon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgecon(armpl_int_t matrix_layout, char norm,
                           armpl_int_t n, const double *a, armpl_int_t lda,
                           double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgecon*, *LAPACKE_dgecon*, *LAPACKE_sgecon* and *LAPACKE_zgecon*. It also exists with a native Fortran interface as *dgecon*.

4.19.672 LAPACKE_dgecon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgecon_work(armpl_int_t matrix_layout, char norm,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, double anorm, double *rcond,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgecon_work*, *LAPACKE_dgecon_work*, *LAPACKE_sgecon_work* and *LAPACKE_zgecon_work*.

4.19.673 LAPACKE_dgeequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeequ(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const double *a, armpl_int_t lda,
                           double *r, double *c, double *rowcnd,
                           double *colcnd, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequ*, *LAPACKE_dgeequ*, *LAPACKE_sgeequ* and *LAPACKE_zgeequ*. It also exists with a native Fortran interface as *dgeequ*.

4.19.674 LAPACKE_dgeequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeequ_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, double *r, double *c,
                                double *rowcnd, double *colcnd,
                                double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequ_work*, *LAPACKE_dgeequ_work*, *LAPACKE_sgeequ_work* and *LAPACKE_zgeequ_work*.

4.19.675 LAPACKE_dgeequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeequb(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, const double *a, armpl_int_t lda,
                            double *r, double *c, double *rowcnd,
                            double *colcnd, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequb*, *LAPACKE_dgeequb*, *LAPACKE_sgeequb* and *LAPACKE_zgeequb*. It also exists with a native Fortran interface as *dgeequb*.

4.19.676 LAPACKE_dgeequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeequb_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, const double *a,
                                 armpl_int_t lda, double *r, double *c,
                                 double *rowcnd, double *colcnd,
                                 double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequb_work*, *LAPACKE_dgeequb_work*, *LAPACKE_sgeequb_work* and *LAPACKE_zgeequb_work*.

4.19.677 LAPACKE_dgees

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgees(armpl_int_t matrix_layout, char jobvs, char sort,
                          LAPACK_D_SELECT2 select, armpl_int_t n, double *a,
                          armpl_int_t lda, armpl_int_t *sdim, double *wr,
                          double *wi, double *vs, armpl_int_t ldvs);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgees*, *LAPACKE_dgees*, *LAPACKE_sgees* and *LAPACKE_zgees*. It also exists with a native Fortran interface as *dgees*.

4.19.678 LAPACKE_dgees_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgees_work(armpl_int_t matrix_layout, char jobvs,
                               char sort, LAPACK_D_SELECT2 select,
                               armpl_int_t n, double *a, armpl_int_t lda,
                               armpl_int_t *sdim, double *wr, double *wi,
                               double *vs, armpl_int_t ldvs, double *work,
                               armpl_int_t lwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgees_work*, *LAPACKE_dgees_work*, *LAPACKE_sgees_work* and *LAPACKE_zgees_work*.

4.19.679 LAPACKE_dgeesx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeesx(armpl_int_t matrix_layout, char jobvs, char sort,
                           LAPACK_D_SELECT2 select, char sense, armpl_int_t n,
                           double *a, armpl_int_t lda, armpl_int_t *sdim,
```

(continues on next page)

(continued from previous page)

```
                                double *wr, double *wi, double *vs,
                                armpl_int_t ldvs, double *rconde, double *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeesx*, *LAPACKE_dgeesx*, *LAPACKE_sgeesx* and *LAPACKE_zgeesx*. It also exists with a native Fortran interface as *dgeesx*.

4.19.680 LAPACKE_dgeesx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeesx_work(armpl_int_t matrix_layout, char jobvs,
                                char sort, LAPACK_D_SELECT2 select,
                                char sense, armpl_int_t n, double *a,
                                armpl_int_t lda, armpl_int_t *sdim,
                                double *wr, double *wi, double *vs,
                                armpl_int_t ldvs, double *rconde,
                                double *rcondv, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeesx_work*, *LAPACKE_dgeesx_work*, *LAPACKE_sgeesx_work* and *LAPACKE_zgeesx_work*.

4.19.681 LAPACKE_dgeev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeev(armpl_int_t matrix_layout, char jobvl, char jobvr,
                          armpl_int_t n, double *a, armpl_int_t lda,
                          double *wr, double *wi, double *vl,
                          armpl_int_t ldvl, double *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeev*, *LAPACKE_dgeev*, *LAPACKE_sgeev* and *LAPACKE_zgeev*. It also exists with a native Fortran interface as *dgeev*.

4.19.682 LAPACKE_dgeev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeev_work(armpl_int_t matrix_layout, char jobvl,
                               char jobvr, armpl_int_t n, double *a,
                               armpl_int_t lda, double *wr, double *wi,
                               double *vl, armpl_int_t ldvl, double *vr,
                               armpl_int_t ldvr, double *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeev_work*, *LAPACKE_dgeev_work*, *LAPACKE_sgeev_work* and *LAPACKE_zgeev_work*.

4.19.683 LAPACKE_dgeevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeevx(armpl_int_t matrix_layout, char balanc, char jobvl,
                           char jobvr, char sense, armpl_int_t n, double *a,
                           armpl_int_t lda, double *wr, double *wi,
                           double *vl, armpl_int_t ldvl, double *vr,
                           armpl_int_t ldvr, armpl_int_t *ilo,
                           armpl_int_t *ihi, double *scale, double *abnrm,
                           double *rconde, double *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeevx*, *LAPACKE_dgeevx*, *LAPACKE_sgeevx* and *LAPACKE_zgeevx*. It also exists with a native Fortran interface as *dgeevx*.

4.19.684 LAPACKE_dgeevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeevx_work(armpl_int_t matrix_layout, char balanc,
                                char jobvl, char jobvr, char sense,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *wr, double *wi, double *vl,
                                armpl_int_t ldvl, double *vr,
                                armpl_int_t ldvr, armpl_int_t *ilo,
                                armpl_int_t *ihi, double *scale,
                                double *abnrm, double *rconde, double *rcondv,
                                double *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeevx_work*, *LAPACKE_dgeevx_work*, *LAPACKE_sgeevx_work* and *LAPACKE_zgeevx_work*.

4.19.685 LAPACKE_dgehrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgehrd(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t ilo, armpl_int_t ihi, double *a,
                           armpl_int_t lda, double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.686 LAPACKE_dgehrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgehrd_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi, double *a,
                                armpl_int_t lda, double *tau, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.687 LAPACKE_dgejsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgejsv(armpl_int_t matrix_layout, char joba, char jobu,
                           char jobv, char jobr, char jobt, char jobp,
                           armpl_int_t m, armpl_int_t n, double *a,
                           armpl_int_t lda, double *sva, double *u,
                           armpl_int_t ldu, double *v, armpl_int_t ldv,
                           double *stat, armpl_int_t *istat);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgejsv*, *LAPACKE_dgejsv*, *LAPACKE_sgejsv* and *LAPACKE_zgejsv*. It also exists with a native Fortran interface as *dgejsv*.

4.19.688 LAPACKE_dgejsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgejsv_work(armpl_int_t matrix_layout, char joba,
                                char jobu, char jobv, char jobr, char jobt,
                                char jobp, armpl_int_t m, armpl_int_t n,
                                double *a, armpl_int_t lda, double *sva,
                                double *u, armpl_int_t ldu, double *v,
                                armpl_int_t ldv, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.689 LAPACKE_dgelq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelq(armpl_int_t matrix_layout, armpl_int_t m,
                          armpl_int_t n, double *a, armpl_int_t lda,
                          double *t, armpl_int_t tsize);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq*, *LAPACKE_dgelq*, *LAPACKE_sgelq* and *LAPACKE_zgelq*. It also exists with a native Fortran interface as *dgelq*.

4.19.690 LAPACKE_dgelq2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelq2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq2*, *LAPACKE_dgelq2*, *LAPACKE_sgelq2* and *LAPACKE_zgelq2*. It also exists with a native Fortran interface as *dgelq2*.

4.19.691 LAPACKE_dgelq2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelq2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *tau, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq2_work*, *LAPACKE_dgelq2_work*, *LAPACKE_sgelq2_work* and *LAPACKE_zgelq2_work*.

4.19.692 LAPACKE_dgelq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelq_work(armpl_int_t matrix_layout, armpl_int_t m,
                               armpl_int_t n, double *a, armpl_int_t lda,
                               double *t, armpl_int_t tsize, double *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq_work*, *LAPACKE_dgelq_work*, *LAPACKE_sgelq_work* and *LAPACKE_zgelq_work*.

4.19.693 LAPACKE_dgelqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelqf*, *LAPACKE_dgelqf*, *LAPACKE_sgelqf* and *LAPACKE_zgelqf*. It also exists with a native Fortran interface as *dgelqf*.

4.19.694 LAPACKE_dgelqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *tau, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelqf_work*, *LAPACKE_dgelqf_work*, *LAPACKE_sgelqf_work* and *LAPACKE_zgelqf_work*.

4.19.695 LAPACKE_dgels

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgels(armpl_int_t matrix_layout, char trans,
                          armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                          double *a, armpl_int_t lda, double *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgels*, *LAPACKE_dgels*, *LAPACKE_sgels* and *LAPACKE_zgels*. It also exists with a native Fortran interface as *dgels*.

4.19.696 LAPACKE_dgels_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgels_work(armpl_int_t matrix_layout, char trans,
                               armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                               double *a, armpl_int_t lda, double *b,
                               armpl_int_t ldb, double *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgels_work*, *LAPACKE_dgels_work*, *LAPACKE_sgels_work* and *LAPACKE_zgels_work*.

4.19.697 LAPACKE_dgelsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelsd(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs, double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb,
                           double *s, double rcond, armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsd*, *LAPACKE_dgelsd*, *LAPACKE_sgelsd* and *LAPACKE_zgelsd*. It also exists with a native Fortran interface as *dgelsd*.

4.19.698 LAPACKE_dgelsd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelsd_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs, double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                double *s, double rcond, armpl_int_t *rank,
                                double *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsd_work*, *LAPACKE_dgelsd_work*, *LAPACKE_sgelsd_work* and *LAPACKE_zgelsd_work*.

4.19.699 LAPACKE_dgelss

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelss(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs, double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb,
                           double *s, double rcond, armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelss*, *LAPACKE_dgelss*, *LAPACKE_sgelss* and *LAPACKE_zgelss*. It also exists with a native Fortran interface as *dgelss*.

4.19.700 LAPACKE_dgelss_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelss_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs, double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                double *s, double rcond, armpl_int_t *rank,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelss_work*, *LAPACKE_dgelss_work*, *LAPACKE_sgelss_work* and *LAPACKE_zgelss_work*.

4.19.701 LAPACKE_dgelsy

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelsy(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs, double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb,
                           armpl_int_t *jpvt, double rcond,
                           armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsy*, *LAPACKE_dgelsy*, *LAPACKE_sgelsy* and *LAPACKE_zgelsy*. It also exists with a native Fortran interface as *dgelsy*.

4.19.702 LAPACKE_dgelsy_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgelsy_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs, double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                armpl_int_t *jpvt, double rcond,
                                armpl_int_t *rank, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsy_work*, *LAPACKE_dgelsy_work*, *LAPACKE_sgelsy_work* and *LAPACKE_zgelsy_work*.

4.19.703 LAPACKE_dgemlq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgemlq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const double *a, armpl_int_t lda, const double *t,
                           armpl_int_t tsize, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemlq*, *LAPACKE_dgemlq*, *LAPACKE_sgemlq* and *LAPACKE_zgemlq*. It also exists with a native Fortran interface as *dgemlq*.

4.19.704 LAPACKE_dgemlq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgemlq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const double *a,
                                armpl_int_t lda, const double *t,
                                armpl_int_t tsize, double *c, armpl_int_t ldc,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemlq_work*, *LAPACKE_dgemlq_work*, *LAPACKE_sgemlq_work* and *LAPACKE_zgemlq_work*.

4.19.705 LAPACKE_dgemqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgemqr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const double *a, armpl_int_t lda, const double *t,
                           armpl_int_t tsize, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqr*, *LAPACKE_dgemqr*, *LAPACKE_sgemqr* and *LAPACKE_zgemqr*. It also exists with a native Fortran interface as *dgemqr*.

4.19.706 LAPACKE_dgemqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgemqr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const double *a,
                                armpl_int_t lda, const double *t,
                                armpl_int_t tsize, double *c, armpl_int_t ldc,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqr_work*, *LAPACKE_dgemqr_work*, *LAPACKE_sgemqr_work* and *LAPACKE_zgemqr_work*.

4.19.707 LAPACKE_dgemqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgemqrt(armpl_int_t matrix_layout, char side, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t k,
                            armpl_int_t nb, const double *v, armpl_int_t ldv,
                            const double *t, armpl_int_t ldt, double *c,
                            armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqrt*, *LAPACKE_dgemqrt*, *LAPACKE_sgemqrt* and *LAPACKE_zgemqrt*. It also exists with a native Fortran interface as *dgemqrt*.

4.19.708 LAPACKE_dgemqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgemqrt_work(armpl_int_t matrix_layout, char side,
                                 char trans, armpl_int_t m, armpl_int_t n,
                                 armpl_int_t k, armpl_int_t nb,
                                 const double *v, armpl_int_t ldv,
```

(continued from previous page)

```
                                const double *t, armpl_int_t ldt, double *c,
                                armpl_int_t ldc, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqrt_work*, *LAPACKE_dgemqrt_work*, *LAPACKE_sgemqrt_work* and *LAPACKE_zgemqrt_work*.

4.19.709 LAPACKE_dgeqlf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqlf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqlf*, *LAPACKE_dgeqlf*, *LAPACKE_sgeqlf* and *LAPACKE_zgeqlf*. It also exists with a native Fortran interface as *dgeqlf*.

4.19.710 LAPACKE_dgeqlf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqlf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *tau, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqlf_work*, *LAPACKE_dgeqlf_work*, *LAPACKE_sgeqlf_work* and *LAPACKE_zgeqlf_work*.

4.19.711 LAPACKE_dgeqp3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqp3(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           armpl_int_t *jpvt, double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqp3*, *LAPACKE_dgeqp3*, *LAPACKE_sgeqp3* and *LAPACKE_zgeqp3*. It also exists with a native Fortran interface as *dgeqp3*.

4.19.712 LAPACKE_dgeqp3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqp3_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                armpl_int_t *jpvt, double *tau, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqp3_work*, *LAPACKE_dgeqp3_work*, *LAPACKE_sgeqp3_work* and *LAPACKE_zgeqp3_work*.

4.19.713 LAPACKE_dgeqpf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqpf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           armpl_int_t *jpvt, double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqpf*, *LAPACKE_dgeqpf*, *LAPACKE_sgeqpf* and *LAPACKE_zgeqpf*.

4.19.714 LAPACKE_dgeqpf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqpf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                armpl_int_t *jpvt, double *tau,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqpf_work*, *LAPACKE_dgeqpf_work*, *LAPACKE_sgeqpf_work* and *LAPACKE_zgeqpf_work*.

4.19.715 LAPACKE_dgeqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqr(armpl_int_t matrix_layout, armpl_int_t m,
                          armpl_int_t n, double *a, armpl_int_t lda,
                          double *t, armpl_int_t tsize);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr*, *LAPACKE_dgeqr*, *LAPACKE_sgeqr* and *LAPACKE_zgeqr*. It also exists with a native Fortran interface as *dgeqr*.

4.19.716 LAPACKE_dgeqr2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqr2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr2*, *LAPACKE_dgeqr2*, *LAPACKE_sgeqr2* and *LAPACKE_zgeqr2*. It also exists with a native Fortran interface as *dgeqr2*.

4.19.717 LAPACKE_dgeqr2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqr2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *tau, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr2_work*, *LAPACKE_dgeqr2_work*, *LAPACKE_sgeqr2_work* and *LAPACKE_zgeqr2_work*.

4.19.718 LAPACKE_dgeqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqr_work(armpl_int_t matrix_layout, armpl_int_t m,
                               armpl_int_t n, double *a, armpl_int_t lda,
                               double *t, armpl_int_t tsize, double *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr_work*, *LAPACKE_dgeqr_work*, *LAPACKE_sgeqr_work* and *LAPACKE_zgeqr_work*.

4.19.719 LAPACKE_dgeqrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrf*, *LAPACKE_dgeqrf*, *LAPACKE_sgeqrf* and *LAPACKE_zgeqrf*. It also exists with a native Fortran interface as *dgeqrf*.

4.19.720 LAPACKE_dgeqrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *tau, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrf_work*, *LAPACKE_dgeqrf_work*, *LAPACKE_sgeqrf_work* and *LAPACKE_zgeqrf_work*.

4.19.721 LAPACKE_dgeqrfp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrfp(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, double *a, armpl_int_t lda,
                            double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrfp*, *LAPACKE_dgeqrfp*, *LAPACKE_sgeqrfp* and *LAPACKE_zgeqrfp*. It also exists with a native Fortran interface as *dgeqrfp*.

4.19.722 LAPACKE_dgeqrfp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrfp_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, double *a, armpl_int_t lda,
                                 double *tau, double *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrfp_work*, *LAPACKE_dgeqrfp_work*, *LAPACKE_sgeqrfp_work* and *LAPACKE_zgeqrfp_work*.

4.19.723 LAPACKE_dgeqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrt(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nb, double *a,
                           armpl_int_t lda, double *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt*, *LAPACKE_dgeqrt*, *LAPACKE_sgeqrt* and *LAPACKE_zgeqrt*. It also exists with a native Fortran interface as *dgeqrt*.

4.19.724 LAPACKE_dgeqrt2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrt2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, double *a, armpl_int_t lda,
                            double *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt2*, *LAPACKE_dgeqrt2*, *LAPACKE_sgeqrt2* and *LAPACKE_zgeqrt2*. It also exists with a native Fortran interface as *dgeqrt2*.

4.19.725 LAPACKE_dgeqrt2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrt2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, double *a, armpl_int_t lda,
                                 double *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt2_work*, *LAPACKE_dgeqrt2_work*, *LAPACKE_sgeqrt2_work* and *LAPACKE_zgeqrt2_work*.

4.19.726 LAPACKE_dgeqrt3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrt3(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, double *a, armpl_int_t lda,
                            double *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt3*, *LAPACKE_dgeqrt3*, *LAPACKE_sgeqrt3* and *LAPACKE_zgeqrt3*. It also exists with a native Fortran interface as *dgeqrt3*.

4.19.727 LAPACKE_dgeqrt3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrt3_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, double *a, armpl_int_t lda,
                                 double *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt3_work*, *LAPACKE_dgeqrt3_work*, *LAPACKE_sgeqrt3_work* and *LAPACKE_zgeqrt3_work*.

4.19.728 LAPACKE_dgeqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgeqrt_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nb, double *a,
                                armpl_int_t lda, double *t, armpl_int_t ldt,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt_work*, *LAPACKE_dgeqrt_work*, *LAPACKE_sgeqrt_work* and *LAPACKE_zgeqrt_work*.

4.19.729 LAPACKE_dgerfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgerfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const double *a,
                           armpl_int_t lda, const double *af,
                           armpl_int_t ldaf, const armpl_int_t *ipiv,
                           const double *b, armpl_int_t ldb, double *x,
                           armpl_int_t ldx, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfs*, *LAPACKE_dgerfs*, *LAPACKE_sgerfs* and *LAPACKE_zgerfs*. It also exists with a native Fortran interface as *dgerfs*.

4.19.730 LAPACKE_dgerfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgerfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *a, armpl_int_t lda,
                                const double *af, armpl_int_t ldaf,
                                const armpl_int_t *ipiv, const double *b,
                                armpl_int_t ldb, double *x, armpl_int_t ldx,
                                double *ferr, double *berr, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.731 LAPACKE_dgerfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgerfsx(armpl_int_t matrix_layout, char trans, char equed,
                            armpl_int_t n, armpl_int_t nrhs, const double *a,
                            armpl_int_t lda, const double *af,
                            armpl_int_t ldaf, const armpl_int_t *ipiv,
                            const double *r, const double *c, const double *b,
                            armpl_int_t ldb, double *x, armpl_int_t ldx,
                            double *rcond, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfsx*, *LAPACKE_dgerfsx*, *LAPACKE_sgerfsx* and *LAPACKE_zgerfsx*. It also exists with a native Fortran interface as *dgerfsx*.

4.19.732 LAPACKE_dgerfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgerfsx_work(armpl_int_t matrix_layout, char trans,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const double *a, armpl_int_t lda,
                                 const double *af, armpl_int_t ldaf,
                                 const armpl_int_t *ipiv, const double *r,
                                 const double *c, const double *b,
                                 armpl_int_t ldb, double *x, armpl_int_t ldx,
                                 double *rcond, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfsx_work*, *LAPACKE_dgerfsx_work*, *LAPACKE_sgerfsx_work* and *LAPACKE_zgerfsx_work*.

4.19.733 LAPACKE_dgerqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgerqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerqf*, *LAPACKE_dgerqf*, *LAPACKE_sgerqf* and *LAPACKE_zgerqf*. It also exists with a native Fortran interface as *dgerqf*.

4.19.734 LAPACKE_dgerqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgerqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *tau, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerqf_work*, *LAPACKE_dgerqf_work*, *LAPACKE_sgerqf_work* and *LAPACKE_zgerqf_work*.

4.19.735 LAPACKE_dgesdd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesdd(armpl_int_t matrix_layout, char jobz,
                           armpl_int_t m, armpl_int_t n, double *a,
                           armpl_int_t lda, double *s, double *u,
                           armpl_int_t ldu, double *vt, armpl_int_t ldvt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesdd*, *LAPACKE_dgesdd*, *LAPACKE_sgesdd* and *LAPACKE_zgesdd*. It also exists with a native Fortran interface as *dgesdd*.

4.19.736 LAPACKE_dgesdd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesdd_work(armpl_int_t matrix_layout, char jobz,
                                armpl_int_t m, armpl_int_t n, double *a,
                                armpl_int_t lda, double *s, double *u,
                                armpl_int_t ldu, double *vt, armpl_int_t ldvt,
                                double *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesdd_work*, *LAPACKE_dgesdd_work*, *LAPACKE_sgesdd_work* and *LAPACKE_zgesdd_work*.

4.19.737 LAPACKE_dgesv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, double *a, armpl_int_t lda,
                          armpl_int_t *ipiv, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesv*, *LAPACKE_dgesv*, *LAPACKE_sgesv* and *LAPACKE_zgesv*. It also exists with a native Fortran interface as *dgesv*.

4.19.738 LAPACKE_dgesv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, double *a, armpl_int_t lda,
                               armpl_int_t *ipiv, double *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesv_work*, *LAPACKE_dgesv_work*, *LAPACKE_sgesv_work* and *LAPACKE_zgesv_work*.

4.19.739 LAPACKE_dgesvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesvd(armpl_int_t matrix_layout, char jobu, char jobvt,
                           armpl_int_t m, armpl_int_t n, double *a,
                           armpl_int_t lda, double *s, double *u,
                           armpl_int_t ldu, double *vt, armpl_int_t ldvt,
                           double *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvd*, *LAPACKE_dgesvd*, *LAPACKE_sgesvd* and *LAPACKE_zgesvd*. It also exists with a native Fortran interface as *dgesvd*.

4.19.740 LAPACKE_dgesvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesvd_work(armpl_int_t matrix_layout, char jobu,
                                char jobvt, armpl_int_t m, armpl_int_t n,
                                double *a, armpl_int_t lda, double *s,
                                double *u, armpl_int_t ldu, double *vt,
                                armpl_int_t ldvt, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvd_work*, *LAPACKE_dgesvd_work*, *LAPACKE_sgesvd_work* and *LAPACKE_zgesvd_work*.

4.19.741 LAPACKE_dgesvdx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesvdx(armpl_int_t matrix_layout, char jobu, char jobvt,
                            char range, armpl_int_t m, armpl_int_t n,
                            double *a, armpl_int_t lda, double vl, double vu,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t il, armpl_int_t iu, armpl_int_t *ns,
                                double *s, double *u, armpl_int_t ldu, double *vt,
                                armpl_int_t ldvt, armpl_int_t *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvdx*, *LAPACKE_dgesvdx*, *LAPACKE_sgesvdx* and *LAPACKE_zgesvdx*. It also exists with a native Fortran interface as *dgesvdx*.

4.19.742 LAPACKE_dgesvdx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesvdx_work(armpl_int_t matrix_layout, char jobu,
                                 char jobvt, char range, armpl_int_t m,
                                 armpl_int_t n, double *a, armpl_int_t lda,
                                 double vl, double vu, armpl_int_t il,
                                 armpl_int_t iu, armpl_int_t *ns, double *s,
                                 double *u, armpl_int_t ldu, double *vt,
                                 armpl_int_t ldvt, double *work,
                                 armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvdx_work*, *LAPACKE_dgesvdx_work*, *LAPACKE_sgesvdx_work* and *LAPACKE_zgesvdx_work*.

4.19.743 LAPACKE_dgesvj

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesvj(armpl_int_t matrix_layout, char joba, char jobu,
                           char jobv, armpl_int_t m, armpl_int_t n, double *a,
                           armpl_int_t lda, double *sva, armpl_int_t mv,
                           double *v, armpl_int_t ldv, double *stat);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvj*, *LAPACKE_dgesvj*, *LAPACKE_sgesvj* and *LAPACKE_zgesvj*. It also exists with a native Fortran interface as *dgesvj*.

4.19.744 LAPACKE_dgesvj_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesvj_work(armpl_int_t matrix_layout, char joba,
                                char jobu, char jobv, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *sva, armpl_int_t mv, double *v,
                                armpl_int_t ldv, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.745 LAPACKE_dgesvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t nrhs, double *a,
                           armpl_int_t lda, double *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, char *equed, double *r,
                           double *c, double *b, armpl_int_t ldb, double *x,
                           armpl_int_t ldx, double *rcond, double *ferr,
                           double *berr, double *rpivot);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.747 LAPACKE_dgesvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesvxx(armpl_int_t matrix_layout, char fact, char trans,
                            armpl_int_t n, armpl_int_t nrhs, double *a,
                            armpl_int_t lda, double *af, armpl_int_t ldaf,
                            armpl_int_t *ipiv, char *equed, double *r,
                            double *c, double *b, armpl_int_t ldb, double *x,
                            armpl_int_t ldx, double *rcond, double *rpvgrw,
                            double *berr, armpl_int_t n_err_bnds,
                            double *err_bnds_norm, double *err_bnds_comp,
                            armpl_int_t nparams, double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvxx*, *LAPACKE_dgesvxx*, *LAPACKE_sgesvxx* and *LAPACKE_zgesvxx*. It also exists with a native Fortran interface as *dgesvxx*.

4.19.748 LAPACKE_dgesvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgesvxx_work(armpl_int_t matrix_layout, char fact,
                                 char trans, armpl_int_t n, armpl_int_t nrhs,
                                 double *a, armpl_int_t lda, double *af,
                                 armpl_int_t ldaf, armpl_int_t *ipiv,
                                 char *equed, double *r, double *c, double *b,
                                 armpl_int_t ldb, double *x, armpl_int_t ldx,
                                 double *rcond, double *rpvgrw, double *berr,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t n_err_bnds,
                                double *err_bnds_norm, double *err_bnds_comp,
                                armpl_int_t nparams, double *params,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvxx_work*, *LAPACKE_dgesvxx_work*, *LAPACKE_sgesvxx_work* and *LAPACKE_zgesvxx_work*.

4.19.749 LAPACKE_dgetf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetf2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetf2*, *LAPACKE_dgetf2*, *LAPACKE_sgetf2* and *LAPACKE_zgetf2*. It also exists with a native Fortran interface as *dgetf2*.

4.19.750 LAPACKE_dgetf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetf2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetf2_work*, *LAPACKE_dgetf2_work*, *LAPACKE_sgetf2_work* and *LAPACKE_zgetf2_work*.

4.19.751 LAPACKE_dgetrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf*, *LAPACKE_dgetrf*, *LAPACKE_sgetrf* and *LAPACKE_zgetrf*. It also exists with a native Fortran interface as *dgetrf*.

4.19.752 LAPACKE_dgetrf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetrf2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, double *a, armpl_int_t lda,
                            armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.753 LAPACKE_dgetrf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetrf2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, double *a, armpl_int_t lda,
                                 armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf2_work*, *LAPACKE_dgetrf2_work*, *LAPACKE_sgetrf2_work* and *LAPACKE_zgetrf2_work*.

4.19.754 LAPACKE_dgetrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf_work*, *LAPACKE_dgetrf_work*, *LAPACKE_sgetrf_work* and *LAPACKE_zgetrf_work*.

4.19.755 LAPACKE_dgetri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetri(armpl_int_t matrix_layout, armpl_int_t n,
                           double *a, armpl_int_t lda,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetri*, *LAPACKE_dgetri*, *LAPACKE_sgetri* and *LAPACKE_zgetri*. It also exists with a native Fortran interface as *dgetri*.

4.19.756 LAPACKE_dgetri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetri_work(armpl_int_t matrix_layout, armpl_int_t n,
                                double *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetri_work*, *LAPACKE_dgetri_work*, *LAPACKE_sgetri_work* and *LAPACKE_zgetri_work*.

4.19.757 LAPACKE_dgetrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const double *a,
                           armpl_int_t lda, const armpl_int_t *ipiv,
                           double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrs*, *LAPACKE_dgetrs*, *LAPACKE_sgetrs* and *LAPACKE_zgetrs*. It also exists with a native Fortran interface as *dgetrs*.

4.19.758 LAPACKE_dgetrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrs_work*, *LAPACKE_dgetrs_work*, *LAPACKE_sgetrs_work* and *LAPACKE_zgetrs_work*.

4.19.759 LAPACKE_dgetsls

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetsls(armpl_int_t matrix_layout, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                            double *a, armpl_int_t lda, double *b,
                            armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetsls*, *LAPACKE_dgetsls*, *LAPACKE_sgetsls* and *LAPACKE_zgetsls*. It also exists with a native Fortran interface as *dgetsls*.

4.19.760 LAPACKE_dgetsls_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgetsls_work(armpl_int_t matrix_layout, char trans,
                                 armpl_int_t m, armpl_int_t n,
                                 armpl_int_t nrhs, double *a, armpl_int_t lda,
                                 double *b, armpl_int_t ldb, double *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetsls_work*, *LAPACKE_dgetsls_work*, *LAPACKE_sgetsls_work* and *LAPACKE_zgetsls_work*.

4.19.761 LAPACKE_dggbak

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggbak(armpl_int_t matrix_layout, char job, char side,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           const double *lscale, const double *rscale,
                           armpl_int_t m, double *v, armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbak*, *LAPACKE_dggbak*, *LAPACKE_sggbak* and *LAPACKE_zggbak*. It also exists with a native Fortran interface as *dggbak*.

4.19.762 LAPACKE_dggbak_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggbak_work(armpl_int_t matrix_layout, char job,
                                char side, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, const double *lscale,
                                const double *rscale, armpl_int_t m,
                                double *v, armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbak_work*, *LAPACKE_dggbak_work*, *LAPACKE_sggbak_work* and *LAPACKE_zggbak_work*.

4.19.763 LAPACKE_dggbal

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggbal(armpl_int_t matrix_layout, char job, armpl_int_t n,
                           double *a, armpl_int_t lda, double *b,
                           armpl_int_t ldb, armpl_int_t *ilo,
                           armpl_int_t *ihi, double *lscale, double *rscale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbal*, *LAPACKE_dggbal*, *LAPACKE_sggbal* and *LAPACKE_zggbal*. It also exists with a native Fortran interface as *dggbal*.

4.19.764 LAPACKE_dggbal_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggbal_work(armpl_int_t matrix_layout, char job,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *b, armpl_int_t ldb, armpl_int_t *ilo,
                                armpl_int_t *ihi, double *lscale,
                                double *rscale, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbal_work*, *LAPACKE_dggbal_work*, *LAPACKE_sggbal_work* and *LAPACKE_zggbal_work*.

4.19.765 LAPACKE_dgges

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgges(armpl_int_t matrix_layout, char jobvsl, char jobvsr,
                          char sort, LAPACK_D_SELECT3 selctg, armpl_int_t n,
                          double *a, armpl_int_t lda, double *b,
                          armpl_int_t ldb, armpl_int_t *sdim, double *alphar,
                          double *alphai, double *beta, double *vsl,
                          armpl_int_t ldvsl, double *vsr, armpl_int_t ldvsr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgges*, *LAPACKE_dgges*, *LAPACKE_sgges* and *LAPACKE_zgges*. It also exists with a native Fortran interface as *dgges*.

4.19.766 LAPACKE_dgges3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgges3(armpl_int_t matrix_layout, char jobvsl,
                           char jobvsr, char sort, LAPACK_D_SELECT3 selctg,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *b, armpl_int_t ldb, armpl_int_t *sdim,
                           double *alphar, double *alphai, double *beta,
                           double *vsl, armpl_int_t ldvsl, double *vsr,
                           armpl_int_t ldvsr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgges3*, *LAPACKE_dgges3*, *LAPACKE_sgges3* and *LAPACKE_zgges3*. It also exists with a native Fortran interface as *dgges3*.

4.19.767 LAPACKE_dgges3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgges3_work(armpl_int_t matrix_layout, char jobvsl,
                                char jobvsr, char sort,
                                LAPACK_D_SELECT3 selctg, armpl_int_t n,
                                double *a, armpl_int_t lda, double *b,
                                armpl_int_t ldb, armpl_int_t *sdim,
                                double *alphar, double *alphai, double *beta,
                                double *vsl, armpl_int_t ldvsl, double *vsr,
                                armpl_int_t ldvsr, double *work,
                                armpl_int_t lwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.768 LAPACKE_dgges_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgges_work(armpl_int_t matrix_layout, char jobvsl,
                               char jobvsr, char sort,
                               LAPACK_D_SELECT3 selctg, armpl_int_t n,
                               double *a, armpl_int_t lda, double *b,
                               armpl_int_t ldb, armpl_int_t *sdim,
                               double *alphar, double *alphai, double *beta,
                               double *vsl, armpl_int_t ldvsl, double *vsr,
                               armpl_int_t ldvsr, double *work,
                               armpl_int_t lwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.771 LAPACKE_dggev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggev(armpl_int_t matrix_layout, char jobvl, char jobvr,
                          armpl_int_t n, double *a, armpl_int_t lda,
                          double *b, armpl_int_t ldb, double *alphar,
                          double *alphai, double *beta, double *vl,
                          armpl_int_t ldvl, double *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.772 LAPACKE_dggev3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggev3(armpl_int_t matrix_layout, char jobvl, char jobvr,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *b, armpl_int_t ldb, double *alphar,
                           double *alphai, double *beta, double *vl,
                           armpl_int_t ldvl, double *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev3*, *LAPACKE_dggev3*, *LAPACKE_sggev3* and *LAPACKE_zggev3*. It also exists with a native Fortran interface as *dggev3*.

4.19.773 LAPACKE_dggev3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggev3_work(armpl_int_t matrix_layout, char jobvl,
                                char jobvr, armpl_int_t n, double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                double *alphar, double *alphai, double *beta,
                                double *vl, armpl_int_t ldvl, double *vr,
                                armpl_int_t ldvr, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev3_work*, *LAPACKE_dggev3_work*, *LAPACKE_sggev3_work* and *LAPACKE_zggev3_work*.

4.19.774 LAPACKE_dggev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggev_work(armpl_int_t matrix_layout, char jobvl,
                               char jobvr, armpl_int_t n, double *a,
                               armpl_int_t lda, double *b, armpl_int_t ldb,
                               double *alphar, double *alphai, double *beta,
                               double *vl, armpl_int_t ldvl, double *vr,
                               armpl_int_t ldvr, double *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev_work*, *LAPACKE_dggev_work*, *LAPACKE_sggev_work* and *LAPACKE_zggev_work*.

4.19.775 LAPACKE_dggevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggevx(armpl_int_t matrix_layout, char balanc, char jobvl,
                           char jobvr, char sense, armpl_int_t n, double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb,
                           double *alphar, double *alphai, double *beta,
                           double *vl, armpl_int_t ldvl, double *vr,
                           armpl_int_t ldvr, armpl_int_t *ilo,
                           armpl_int_t *ihi, double *lscale, double *rscale,
                           double *abnrm, double *bbnrm, double *rconde,
                           double *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggevx*, *LAPACKE_dggevx*, *LAPACKE_sggevx* and *LAPACKE_zggevx*. It also exists with a native Fortran interface as *dggevx*.

4.19.776 LAPACKE_dggevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggevx_work(armpl_int_t matrix_layout, char balanc,
                                char jobvl, char jobvr, char sense,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *b, armpl_int_t ldb, double *alphar,
                                double *alphai, double *beta, double *vl,
                                armpl_int_t ldvl, double *vr,
                                armpl_int_t ldvr, armpl_int_t *ilo,
                                armpl_int_t *ihi, double *lscale,
                                double *rscale, double *abnrm, double *bbnrm,
                                double *rconde, double *rcondv, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggevx_work*, *LAPACKE_dggevx_work*, *LAPACKE_sggevx_work* and *LAPACKE_zggevx_work*.

4.19.777 LAPACKE_dggglm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggglm(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t m, armpl_int_t p, double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb,
                           double *d, double *x, double *y);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggglm*, *LAPACKE_dggglm*, *LAPACKE_sggglm* and *LAPACKE_zggglm*. It also exists with a native Fortran interface as *dggglm*.

4.19.778 LAPACKE_dggglm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggglm_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t m, armpl_int_t p, double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                double *d, double *x, double *y, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggglm_work*, *LAPACKE_dggglm_work*, *LAPACKE_sggglm_work* and *LAPACKE_zggglm_work*.

4.19.779 LAPACKE_dgghd3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgghd3(armpl_int_t matrix_layout, char compq, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           double *a, armpl_int_t lda, double *b,
                           armpl_int_t ldb, double *q, armpl_int_t ldq,
                           double *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghd3*, *LAPACKE_dgghd3*, *LAPACKE_sgghd3* and *LAPACKE_zgghd3*. It also exists with a native Fortran interface as *dgghd3*.

4.19.780 LAPACKE_dgghd3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgghd3_work(armpl_int_t matrix_layout, char compq,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, double *a, armpl_int_t lda,
                                double *b, armpl_int_t ldb, double *q,
                                armpl_int_t ldq, double *z, armpl_int_t ldz,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghd3_work*, *LAPACKE_dgghd3_work*, *LAPACKE_sgghd3_work* and *LAPACKE_zgghd3_work*.

4.19.781 LAPACKE_dgghrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgghrd(armpl_int_t matrix_layout, char compq, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           double *a, armpl_int_t lda, double *b,
                           armpl_int_t ldb, double *q, armpl_int_t ldq,
                           double *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghrd*, *LAPACKE_dgghrd*, *LAPACKE_sgghrd* and *LAPACKE_zgghrd*. It also exists with a native Fortran interface as *dgghrd*.

4.19.782 LAPACKE_dgghrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgghrd_work(armpl_int_t matrix_layout, char compq,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, double *a, armpl_int_t lda,
                                double *b, armpl_int_t ldb, double *q,
                                armpl_int_t ldq, double *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghrd_work*, *LAPACKE_dgghrd_work*, *LAPACKE_sgghrd_work* and *LAPACKE_zgghrd_work*.

4.19.783 LAPACKE_dgglse

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgglse(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t p, double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb,
                           double *c, double *d, double *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgglse*, *LAPACKE_dgglse*, *LAPACKE_sgglse* and *LAPACKE_zgglse*. It also exists with a native Fortran interface as *dgglse*.

4.19.784 LAPACKE_dgglse_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgglse_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t p, double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                double *c, double *d, double *x, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgglse_work*, *LAPACKE_dgglse_work*, *LAPACKE_sgglse_work* and *LAPACKE_zgglse_work*.

4.19.785 LAPACKE_dggqrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggqrf(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t m, armpl_int_t p, double *a,
                           armpl_int_t lda, double *taua, double *b,
                           armpl_int_t ldb, double *taub);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggqrf*, *LAPACKE_dggqrf*, *LAPACKE_sggqrf* and *LAPACKE_zggqrf*. It also exists with a native Fortran interface as *dggqrf*.

4.19.786 LAPACKE_dggqrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggqrf_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t m, armpl_int_t p, double *a,
                                armpl_int_t lda, double *taua, double *b,
                                armpl_int_t ldb, double *taub, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggqrf_work*, *LAPACKE_dggqrf_work*, *LAPACKE_sggqrf_work* and *LAPACKE_zggqrf_work*.

4.19.787 LAPACKE_dggrqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggrqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t p, armpl_int_t n, double *a,
                           armpl_int_t lda, double *taua, double *b,
                           armpl_int_t ldb, double *taub);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggrqf*, *LAPACKE_dggrqf*, *LAPACKE_sggrqf* and *LAPACKE_zggrqf*. It also exists with a native Fortran interface as *dggrqf*.

4.19.788 LAPACKE_dggrqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggrqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n, double *a,
                                armpl_int_t lda, double *taua, double *b,
                                armpl_int_t ldb, double *taub, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.789 LAPACKE_dggsvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggsvd(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t n,
                           armpl_int_t p, armpl_int_t *k, armpl_int_t *l,
                           double *a, armpl_int_t lda, double *b,
                           armpl_int_t ldb, double *alpha, double *beta,
                           double *u, armpl_int_t ldu, double *v,
                           armpl_int_t ldv, double *q, armpl_int_t ldq,
                           armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd*, *LAPACKE_dggsvd*, *LAPACKE_sggsvd* and *LAPACKE_zggsvd*.

4.19.790 LAPACKE_dggsvd3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggsvd3(armpl_int_t matrix_layout, char jobu, char jobv,
                            char jobq, armpl_int_t m, armpl_int_t n,
                            armpl_int_t p, armpl_int_t *k, armpl_int_t *l,
                            double *a, armpl_int_t lda, double *b,
                            armpl_int_t ldb, double *alpha, double *beta,
                            double *u, armpl_int_t ldu, double *v,
                            armpl_int_t ldv, double *q, armpl_int_t ldq,
                            armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd3*, *LAPACKE_dggsvd3*, *LAPACKE_sggsvd3* and *LAPACKE_zggsvd3*. It also exists with a native Fortran interface as *dggsvd3*.

4.19.791 LAPACKE_dggsvd3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggsvd3_work(armpl_int_t matrix_layout, char jobu,
                                 char jobv, char jobq, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t p, armpl_int_t *k,
                                 armpl_int_t *l, double *a, armpl_int_t lda,
                                 double *b, armpl_int_t ldb, double *alpha,
                                 double *beta, double *u, armpl_int_t ldu,
                                 double *v, armpl_int_t ldv, double *q,
                                 armpl_int_t ldq, double *work,
                                 armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd3_work*, *LAPACKE_dggsvd3_work*, *LAPACKE_sggsvd3_work* and *LAPACKE_zggsvd3_work*.

4.19.792 LAPACKE_dggsvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggsvd_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t n, armpl_int_t p, armpl_int_t *k,
                                armpl_int_t *l, double *a, armpl_int_t lda,
                                double *b, armpl_int_t ldb, double *alpha,
                                double *beta, double *u, armpl_int_t ldu,
                                double *v, armpl_int_t ldv, double *q,
                                armpl_int_t ldq, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd_work*, *LAPACKE_dggsvd_work*, *LAPACKE_sggsvd_work* and *LAPACKE_zggsvd_work*.

4.19.793 LAPACKE_dggsvp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggsvp(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t p,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *b, armpl_int_t ldb, double tola,
                           double tolb, armpl_int_t *k, armpl_int_t *l,
                           double *u, armpl_int_t ldu, double *v,
                           armpl_int_t ldv, double *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp*, *LAPACKE_dggsvp*, *LAPACKE_sggsvp* and *LAPACKE_zggsvp*.

4.19.794 LAPACKE_dggsvp3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggsvp3(armpl_int_t matrix_layout, char jobu, char jobv,
                            char jobq, armpl_int_t m, armpl_int_t p,
                            armpl_int_t n, double *a, armpl_int_t lda,
                            double *b, armpl_int_t ldb, double tola,
                            double tolb, armpl_int_t *k, armpl_int_t *l,
                            double *u, armpl_int_t ldu, double *v,
                            armpl_int_t ldv, double *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp3*, *LAPACKE_dggsvp3*, *LAPACKE_sggsvp3* and *LAPACKE_zggsvp3*. It also exists with a native Fortran interface as *dggsvp3*.

4.19.795 LAPACKE_dggsvp3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggsvp3_work(armpl_int_t matrix_layout, char jobu,
                                 char jobv, char jobq, armpl_int_t m,
                                 armpl_int_t p, armpl_int_t n, double *a,
                                 armpl_int_t lda, double *b, armpl_int_t ldb,
                                 double tola, double tolb, armpl_int_t *k,
                                 armpl_int_t *l, double *u, armpl_int_t ldu,
                                 double *v, armpl_int_t ldv, double *q,
                                 armpl_int_t ldq, armpl_int_t *iwork,
                                 double *tau, double *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp3_work*, *LAPACKE_dggsvp3_work*, *LAPACKE_sggsvp3_work* and *LAPACKE_zggsvp3_work*.

4.19.796 LAPACKE_dggsvp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dggsvp_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n, double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                double tola, double tolb, armpl_int_t *k,
                                armpl_int_t *l, double *u, armpl_int_t ldu,
                                double *v, armpl_int_t ldv, double *q,
                                armpl_int_t ldq, armpl_int_t *iwork,
                                double *tau, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp_work*, *LAPACKE_dggsvp_work*, *LAPACKE_sggsvp_work* and *LAPACKE_zggsvp_work*.

4.19.797 LAPACKE_dgtcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgtcon(char norm, armpl_int_t n, const double *dl,
                           const double *d, const double *du,
                           const double *du2, const armpl_int_t *ipiv,
                           double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtcon*, *LAPACKE_dgtcon*, *LAPACKE_sgtcon* and *LAPACKE_zgtcon*. It also exists with a native Fortran interface as *dgtcon*.

4.19.798 LAPACKE_dgtcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgtcon_work(char norm, armpl_int_t n, const double *dl,
                                const double *d, const double *du,
                                const double *du2, const armpl_int_t *ipiv,
                                double anorm, double *rcond, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtcon_work*, *LAPACKE_dgtcon_work*, *LAPACKE_sgtcon_work* and *LAPACKE_zgtcon_work*.

4.19.799 LAPACKE_dgtrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgtrfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const double *dl,
                           const double *d, const double *du,
                           const double *dlf, const double *df,
                           const double *duf, const double *du2,
                           const armpl_int_t *ipiv, const double *b,
                           armpl_int_t ldb, double *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtrfs*, *LAPACKE_dgtrfs*, *LAPACKE_sgtrfs* and *LAPACKE_zgtrfs*. It also exists with a native Fortran interface as *dgtrfs*.

4.19.800 LAPACKE_dgtrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgtrfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *dl, const double *d,
                                const double *du, const double *dlf,
                                const double *df, const double *duf,
                                const double *du2, const armpl_int_t *ipiv,
                                const double *b, armpl_int_t ldb, double *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtrfs_work*, *LAPACKE_dgtrfs_work*, *LAPACKE_sgtrfs_work* and *LAPACKE_zgtrfs_work*.

4.19.801 LAPACKE_dgtsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgtsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, double *dl, double *d, double *du,
                          double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsv*, *LAPACKE_dgtsv*, *LAPACKE_sgtsv* and *LAPACKE_zgtsv*. It also exists with a native Fortran interface as *dgtsv*.

4.19.802 LAPACKE_dgtsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgtsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, double *dl, double *d,
                               double *du, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsv_work*, *LAPACKE_dgtsv_work*, *LAPACKE_sgtsv_work* and *LAPACKE_zgtsv_work*.

4.19.803 LAPACKE_dgtsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgtsvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const double *dl,
                           const double *d, const double *du, double *dlf,
                           double *df, double *duf, double *du2,
                           armpl_int_t *ipiv, const double *b,
                           armpl_int_t ldb, double *x, armpl_int_t ldx,
                           double *rcond, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsvx*, *LAPACKE_dgtsvx*, *LAPACKE_sgtsvx* and *LAPACKE_zgtsvx*. It also exists with a native Fortran interface as *dgtsvx*.

4.19.804 LAPACKE_dgtsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgtsvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t nrhs,
                                const double *dl, const double *d,
                                const double *du, double *dlf, double *df,
                                double *duf, double *du2, armpl_int_t *ipiv,
                                const double *b, armpl_int_t ldb, double *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsvx_work*, *LAPACKE_dgtsvx_work*, *LAPACKE_sgtsvx_work* and *LAPACKE_zgtsvx_work*.

4.19.805 LAPACKE_dgttrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgttrf(armpl_int_t n, double *dl, double *d, double *du,
                           double *du2, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrf*, *LAPACKE_dgttrf*, *LAPACKE_sgttrf* and *LAPACKE_zgttrf*. It also exists with a native Fortran interface as *dgttrf*.

4.19.806 LAPACKE_dgttrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgttrf_work(armpl_int_t n, double *dl, double *d,
                                double *du, double *du2, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrf_work*, *LAPACKE_dgttrf_work*, *LAPACKE_sgttrf_work* and *LAPACKE_zgttrf_work*.

4.19.807 LAPACKE_dgttrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgttrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const double *dl,
                           const double *d, const double *du,
                           const double *du2, const armpl_int_t *ipiv,
                           double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrs*, *LAPACKE_dgttrs*, *LAPACKE_sgttrs* and *LAPACKE_zgttrs*. It also exists with a native Fortran interface as *dgttrs*.

4.19.808 LAPACKE_dgttrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dgttrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *dl, const double *d,
                                const double *du, const double *du2,
```

(continues on next page)

(continued from previous page)

```
                                const armpl_int_t *ipiv, double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrs_work*, *LAPACKE_dgttrs_work*, *LAPACKE_sgttrs_work* and *LAPACKE_zgttrs_work*.

4.19.809 LAPACKE_dhgeqz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dhgeqz(armpl_int_t matrix_layout, char job, char compq,
                           char compz, armpl_int_t n, armpl_int_t ilo,
                           armpl_int_t ihi, double *h, armpl_int_t ldh,
                           double *t, armpl_int_t ldt, double *alphar,
                           double *alphai, double *beta, double *q,
                           armpl_int_t ldq, double *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chgeqz*, *LAPACKE_dhgeqz*, *LAPACKE_shgeqz* and *LAPACKE_zhgeqz*. It also exists with a native Fortran interface as *dhgeqz*.

4.19.810 LAPACKE_dhgeqz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dhgeqz_work(armpl_int_t matrix_layout, char job,
                                char compq, char compz, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi, double *h,
                                armpl_int_t ldh, double *t, armpl_int_t ldt,
                                double *alphar, double *alphai, double *beta,
                                double *q, armpl_int_t ldq, double *z,
                                armpl_int_t ldz, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chgeqz_work*, *LAPACKE_dhgeqz_work*, *LAPACKE_shgeqz_work* and *LAPACKE_zhgeqz_work*.

4.19.811 LAPACKE_dhsein

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dhsein(armpl_int_t matrix_layout, char job, char eigsrc,
                           char initv, armpl_int_t *select, armpl_int_t n,
                           const double *h, armpl_int_t ldh, double *wr,
                           const double *wi, double *vl, armpl_int_t ldvl,
                           double *vr, armpl_int_t ldvr, armpl_int_t mm,
                           armpl_int_t *m, armpl_int_t *ifaill,
                           armpl_int_t *ifailr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chsein*, *LAPACKE_dhsein*, *LAPACKE_shsein* and *LAPACKE_zhsein*. It also exists with a native Fortran interface as *dhsein*.

4.19.812 LAPACKE_dhsein_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dhsein_work(armpl_int_t matrix_layout, char job,
                                char eigsrc, char initv, armpl_int_t *select,
                                armpl_int_t n, const double *h,
                                armpl_int_t ldh, double *wr, const double *wi,
                                double *vl, armpl_int_t ldvl, double *vr,
                                armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, double *work,
                                armpl_int_t *ifaill, armpl_int_t *ifailr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chsein_work*, *LAPACKE_dhsein_work*, *LAPACKE_shsein_work* and *LAPACKE_zhsein_work*.

4.19.813 LAPACKE_dhseqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dhseqr(armpl_int_t matrix_layout, char job, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           double *h, armpl_int_t ldh, double *wr, double *wi,
                           double *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chseqr*, *LAPACKE_dhseqr*, *LAPACKE_shseqr* and *LAPACKE_zhseqr*. It also exists with a native Fortran interface as *dhseqr*.

4.19.814 LAPACKE_dhseqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dhseqr_work(armpl_int_t matrix_layout, char job,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, double *h, armpl_int_t ldh,
                                double *wr, double *wi, double *z,
                                armpl_int_t ldz, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chseqr_work*, *LAPACKE_dhseqr_work*, *LAPACKE_shseqr_work* and *LAPACKE_zhseqr_work*.

4.19.815 LAPACKE_dlacn2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlacn2(armpl_int_t n, double *v, double *x,
                           armpl_int_t *isgn, double *est, armpl_int_t *kase,
                           armpl_int_t *isave);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacn2*, *LAPACKE_dlacn2*, *LAPACKE_slacn2* and *LAPACKE_zlacn2*. It also exists with a native Fortran interface as *dlacn2*.

4.19.816 LAPACKE_dlacn2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlacn2_work(armpl_int_t n, double *v, double *x,
                                armpl_int_t *isgn, double *est,
                                armpl_int_t *kase, armpl_int_t *isave);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacn2_work*, *LAPACKE_dlacn2_work*, *LAPACKE_slacn2_work* and *LAPACKE_zlacn2_work*.

4.19.817 LAPACKE_dlacpy

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlacpy(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n, const double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacpy*, *LAPACKE_dlacpy*, *LAPACKE_slacpy* and *LAPACKE_zlacpy*. It also exists with a native Fortran interface as *dlacpy*.

4.19.818 LAPACKE_dlacpy_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlacpy_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n, const double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacpy_work*, *LAPACKE_dlacpy_work*, *LAPACKE_slacpy_work* and *LAPACKE_zlacpy_work*.

4.19.819 LAPACKE_dlag2s

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlag2s(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const double *a, armpl_int_t lda,
                           float *sa, armpl_int_t ldsa);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlag2s*. It also exists with a native Fortran interface as *dlag2s*.

4.19.820 LAPACKE_dlag2s_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlag2s_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, float *sa,
                                armpl_int_t ldsa);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlag2s_work*.

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.825 LAPACKE_dlamch

Syntax

```
#include "armpl.h"

double LAPACKE_dlamch(char cmach);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlamch* and *LAPACKE_slamch*.

4.19.826 LAPACKE_dlamch_work

Syntax

```
#include "armpl.h"

double LAPACKE_dlamch_work(char cmach);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlamch_work* and *LAPACKE_slamch_work*.

4.19.827 LAPACKE_dlange

Syntax

```
#include "armpl.h"

double LAPACKE_dlange(armpl_int_t matrix_layout, char norm, armpl_int_t m,
                      armpl_int_t n, const double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clange*, *LAPACKE_dlange*, *LAPACKE_slange* and *LAPACKE_zlange*. It also exists with a native Fortran interface as *dlange*.

4.19.828 LAPACKE_dlange_work

Syntax

```
#include "armpl.h"

double LAPACKE_dlange_work(armpl_int_t matrix_layout, char norm,
                           armpl_int_t m, armpl_int_t n, const double *a,
                           armpl_int_t lda, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clange_work*, *LAPACKE_dlange_work*, *LAPACKE_slange_work* and *LAPACKE_zlange_work*.

4.19.829 LAPACKE_dlansy

Syntax

```
#include "armpl.h"

double LAPACKE_dlansy(armpl_int_t matrix_layout, char norm, char uplo,
                      armpl_int_t n, const double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clansy*, *LAPACKE_dlansy*, *LAPACKE_slansy* and *LAPACKE_zlansy*. It also exists with a native Fortran interface as *dlansy*.

4.19.830 LAPACKE_dlansy_work

Syntax

```
#include "armpl.h"

double LAPACKE_dlansy_work(armpl_int_t matrix_layout, char norm, char uplo,
                           armpl_int_t n, const double *a, armpl_int_t lda,
                           double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clansy_work*, *LAPACKE_dlansy_work*, *LAPACKE_slansy_work* and *LAPACKE_zlansy_work*.

4.19.831 LAPACKE_dlantr

Syntax

```
#include "armpl.h"

double LAPACKE_dlantr(armpl_int_t matrix_layout, char norm, char uplo,
                      char diag, armpl_int_t m, armpl_int_t n,
                      const double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clantr*, *LAPACKE_dlantr*, *LAPACKE_slantr* and *LAPACKE_zlantr*. It also exists with a native Fortran interface as *dlantr*.

4.19.832 LAPACKE_dlantr_work

Syntax

```
#include "armpl.h"

double LAPACKE_dlantr_work(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t m, armpl_int_t n,
                           const double *a, armpl_int_t lda, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clantr_work*, *LAPACKE_dlantr_work*, *LAPACKE_slantr_work* and *LAPACKE_zlantr_work*.

4.19.833 LAPACKE_dlapmr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlapmr(armpl_int_t matrix_layout, armpl_int_t forwrd,
                           armpl_int_t m, armpl_int_t n, double *x,
                           armpl_int_t ldx, armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmr*, *LAPACKE_dlapmr*, *LAPACKE_slapmr* and *LAPACKE_zlapmr*. It also exists with a native Fortran interface as *dlapmr*.

4.19.834 LAPACKE_dlapmr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlapmr_work(armpl_int_t matrix_layout, armpl_int_t forwrd,
                                armpl_int_t m, armpl_int_t n, double *x,
                                armpl_int_t ldx, armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmr_work*, *LAPACKE_dlapmr_work*, *LAPACKE_slapmr_work* and *LAPACKE_zlapmr_work*.

4.19.835 LAPACKE_dlapmt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlapmt(armpl_int_t matrix_layout, armpl_int_t forwrd,
                           armpl_int_t m, armpl_int_t n, double *x,
                           armpl_int_t ldx, armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmt*, *LAPACKE_dlapmt*, *LAPACKE_slapmt* and *LAPACKE_zlapmt*. It also exists with a native Fortran interface as *dlapmt*.

4.19.836 LAPACKE_dlapmt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlapmt_work(armpl_int_t matrix_layout, armpl_int_t forwrd,
                                armpl_int_t m, armpl_int_t n, double *x,
                                armpl_int_t ldx, armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmt_work*, *LAPACKE_dlapmt_work*, *LAPACKE_slapmt_work* and *LAPACKE_zlapmt_work*.

4.19.837 LAPACKE_dlapy2

Syntax

```
#include "armpl.h"

double LAPACKE_dlapy2(double x, double y);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlapy2* and *LAPACKE_slapy2*. It also exists with a native Fortran interface as *dlapy2*.

4.19.838 LAPACKE_dlapy2_work

Syntax

```
#include "armpl.h"

double LAPACKE_dlapy2_work(double x, double y);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlapy2_work* and *LAPACKE_slapy2_work*.

4.19.839 LAPACKE_dlapy3

Syntax

```
#include "armpl.h"

double LAPACKE_dlapy3(double x, double y, double z);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlapy3* and *LAPACKE_slapy3*. It also exists with a native Fortran interface as *dlapy3*.

4.19.840 LAPACKE_dlapy3_work

Syntax

```
#include "armpl.h"

double LAPACKE_dlapy3_work(double x, double y, double z);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlapy3_work* and *LAPACKE_slapy3_work*.

4.19.841 LAPACKE_dlarfb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarfb(armpl_int_t matrix_layout, char side, char trans,
                           char direct, char storev, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, const double *v,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldv, const double *t, armpl_int_t ldt,
                                double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfb*, *LAPACKE_dlarfb*, *LAPACKE_slarfb* and *LAPACKE_zlarfb*. It also exists with a native Fortran interface as *dlarfb*.

4.19.842 LAPACKE_dlarfb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarfb_work(armpl_int_t matrix_layout, char side,
                                char trans, char direct, char storev,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                const double *v, armpl_int_t ldv,
                                const double *t, armpl_int_t ldt, double *c,
                                armpl_int_t ldc, double *work,
                                armpl_int_t ldwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfb_work*, *LAPACKE_dlarfb_work*, *LAPACKE_slarfb_work* and *LAPACKE_zlarfb_work*.

4.19.843 LAPACKE_dlarfg

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarfg(armpl_int_t n, double *alpha, double *x,
                           armpl_int_t incx, double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfg*, *LAPACKE_dlarfg*, *LAPACKE_slarfg* and *LAPACKE_zlarfg*. It also exists with a native Fortran interface as *dlarfg*.

4.19.844 LAPACKE_dlarfg_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarfg_work(armpl_int_t n, double *alpha, double *x,
                                armpl_int_t incx, double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfg_work*, *LAPACKE_dlarfg_work*, *LAPACKE_slarfg_work* and *LAPACKE_zlarfg_work*.

4.19.845 LAPACKE_dlarft

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarft(armpl_int_t matrix_layout, char direct,
                           char storev, armpl_int_t n, armpl_int_t k,
                           const double *v, armpl_int_t ldv,
                           const double *tau, double *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarft*, *LAPACKE_dlarft*, *LAPACKE_slarft* and *LAPACKE_zlarft*. It also exists with a native Fortran interface as *dlarft*.

4.19.846 LAPACKE_dlarft_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarft_work(armpl_int_t matrix_layout, char direct,
                                char storev, armpl_int_t n, armpl_int_t k,
                                const double *v, armpl_int_t ldv,
                                const double *tau, double *t,
                                armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarft_work*, *LAPACKE_dlarft_work*, *LAPACKE_slarft_work* and *LAPACKE_zlarft_work*.

4.19.847 LAPACKE_dlarfx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarfx(armpl_int_t matrix_layout, char side,
                           armpl_int_t m, armpl_int_t n, const double *v,
                           double tau, double *c, armpl_int_t ldc,
                           double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfx*, *LAPACKE_dlarfx*, *LAPACKE_slarfx* and *LAPACKE_zlarfx*. It also exists with a native Fortran interface as *dlarfx*.

4.19.848 LAPACKE_dlarfx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarfx_work(armpl_int_t matrix_layout, char side,
                                armpl_int_t m, armpl_int_t n, const double *v,
                                double tau, double *c, armpl_int_t ldc,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfx_work*, *LAPACKE_dlarfx_work*, *LAPACKE_slarfx_work* and *LAPACKE_zlarfx_work*.

4.19.849 LAPACKE_dlarnv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarnv(armpl_int_t idist, armpl_int_t *iseed,
                           armpl_int_t n, double *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarnv*, *LAPACKE_dlarnv*, *LAPACKE_slarnv* and *LAPACKE_zlarnv*. It also exists with a native Fortran interface as *dlarnv*.

4.19.850 LAPACKE_dlarnv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlarnv_work(armpl_int_t idist, armpl_int_t *iseed,
                                armpl_int_t n, double *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarnv_work*, *LAPACKE_dlarnv_work*, *LAPACKE_slarnv_work* and *LAPACKE_zlarnv_work*.

4.19.851 LAPACKE_dlartgp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlartgp(double f, double g, double *cs, double *sn,
                            double *r);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlartgp* and *LAPACKE_slartgp*. It also exists with a native Fortran interface as *dlartgp*.

4.19.852 LAPACKE_dlartgp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlartgp_work(double f, double g, double *cs, double *sn,
                                 double *r);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlartgp_work* and *LAPACKE_slartgp_work*.

4.19.853 LAPACKE_dlartgs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlartgs(double x, double y, double sigma, double *cs,
                            double *sn);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlartgs* and *LAPACKE_slartgs*. It also exists with a native Fortran interface as *dlartgs*.

4.19.854 LAPACKE_dlartgs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlartgs_work(double x, double y, double sigma, double *cs,
                                 double *sn);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlartgs_work* and *LAPACKE_slartgs_work*.

4.19.855 LAPACKE_dlascl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlascl(armpl_int_t matrix_layout, char type,
                           armpl_int_t kl, armpl_int_t ku, double cfrom,
                           double cto, armpl_int_t m, armpl_int_t n,
                           double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clascl*, *LAPACKE_dlascl*, *LAPACKE_slascl* and *LAPACKE_zlascl*. It also exists with a native Fortran interface as *dlascl*.

4.19.856 LAPACKE_dlascl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlascl_work(armpl_int_t matrix_layout, char type,
                                armpl_int_t kl, armpl_int_t ku, double cfrom,
                                double cto, armpl_int_t m, armpl_int_t n,
                                double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clascl_work*, *LAPACKE_dlascl_work*, *LAPACKE_slascl_work* and *LAPACKE_zlascl_work*.

4.19.857 LAPACKE_dlaset

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlaset(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n, double alpha,
                           double beta, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claset*, *LAPACKE_dlaset*, *LAPACKE_slaset* and *LAPACKE_zlaset*. It also exists with a native Fortran interface as *dlaset*.

4.19.858 LAPACKE_dlaset_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlaset_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n, double alpha,
                                double beta, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claset_work*, *LAPACKE_dlaset_work*, *LAPACKE_slaset_work* and *LAPACKE_zlaset_work*.

4.19.859 LAPACKE_dlasrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlasrt(char id, armpl_int_t n, double *d);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlasrt* and *LAPACKE_slasrt*. It also exists with a native Fortran interface as *dlasrt*.

4.19.860 LAPACKE_dlasrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlasrt_work(char id, armpl_int_t n, double *d);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlasrt_work* and *LAPACKE_slasrt_work*.

4.19.861 LAPACKE_dlassq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlassq(armpl_int_t n, double *x, armpl_int_t incx,
                           double *scale, double *sumsq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_classq*, *LAPACKE_dlassq*, *LAPACKE_slassq* and *LAPACKE_zlassq*. It also exists with a native Fortran interface as *dlassq*.

4.19.862 LAPACKE_dlassq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlassq_work(armpl_int_t n, double *x, armpl_int_t incx,
                                double *scale, double *sumsq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_classq_work*, *LAPACKE_dlassq_work*, *LAPACKE_slassq_work* and *LAPACKE_zlassq_work*.

4.19.863 LAPACKE_dlaswp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlaswp(armpl_int_t matrix_layout, armpl_int_t n,
                           double *a, armpl_int_t lda, armpl_int_t k1,
                           armpl_int_t k2, const armpl_int_t *ipiv,
                           armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claswp*, *LAPACKE_dlaswp*, *LAPACKE_slaswp* and *LAPACKE_zlaswp*. It also exists with a native Fortran interface as *dlaswp*.

4.19.864 LAPACKE_dlaswp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlaswp_work(armpl_int_t matrix_layout, armpl_int_t n,
                                double *a, armpl_int_t lda, armpl_int_t k1,
                                armpl_int_t k2, const armpl_int_t *ipiv,
                                armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claswp_work*, *LAPACKE_dlaswp_work*, *LAPACKE_slaswp_work* and *LAPACKE_zlaswp_work*.

4.19.865 LAPACKE_dlatms

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.866 LAPACKE_dlatms_work

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.867 LAPACKE_dlauum

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlauum(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clauum*, *LAPACKE_dlauum*, *LAPACKE_slauum* and *LAPACKE_zlauum*. It also exists with a native Fortran interface as *dlauum*.

4.19.868 LAPACKE_dlauum_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dlauum_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clauum_work*, *LAPACKE_dlauum_work*, *LAPACKE_slauum_work* and *LAPACKE_zlauum_work*.

4.19.869 LAPACKE_dopgtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dopgtr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const double *ap, const double *tau,
                           double *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dopgtr* and *LAPACKE_sopgtr*. It also exists with a native Fortran interface as *dopgtr*.

4.19.870 LAPACKE_dopgtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dopgtr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const double *ap,
                                const double *tau, double *q, armpl_int_t ldq,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dopgtr_work* and *LAPACKE_sopgtr_work*.

4.19.871 LAPACKE_dopmtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dopmtr(armpl_int_t matrix_layout, char side, char uplo,
                           char trans, armpl_int_t m, armpl_int_t n,
                           const double *ap, const double *tau, double *c,
                           armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dopmtr* and *LAPACKE_sopmtr*. It also exists with a native Fortran interface as *dopmtr*.

4.19.872 LAPACKE_dopmtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dopmtr_work(armpl_int_t matrix_layout, char side,
                                char uplo, char trans, armpl_int_t m,
                                armpl_int_t n, const double *ap,
                                const double *tau, double *c, armpl_int_t ldc,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dopmtr_work* and *LAPACKE_sopmtr_work*.

4.19.873 LAPACKE_dorbdb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorbdb(armpl_int_t matrix_layout, char trans, char signs,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           double *x11, armpl_int_t ldx11, double *x12,
                           armpl_int_t ldx12, double *x21, armpl_int_t ldx21,
                           double *x22, armpl_int_t ldx22, double *theta,
                           double *phi, double *taup1, double *taup2,
                           double *tauq1, double *tauq2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorbdb* and *LAPACKE_sorbdb*. It also exists with a native Fortran interface as *dorbdb*.

4.19.874 LAPACKE_dorbdb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorbdb_work(armpl_int_t matrix_layout, char trans,
                                char signs, armpl_int_t m, armpl_int_t p,
                                armpl_int_t q, double *x11, armpl_int_t ldx11,
                                double *x12, armpl_int_t ldx12, double *x21,
                                armpl_int_t ldx21, double *x22,
                                armpl_int_t ldx22, double *theta, double *phi,
                                double *taup1, double *taup2, double *tauq1,
                                double *tauq2, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorbdb_work* and *LAPACKE_sorbdb_work*.

4.19.875 LAPACKE_dorcsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorcsd(armpl_int_t matrix_layout, char jobu1, char jobu2,
                           char jobv1t, char jobv2t, char trans, char signs,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           double *x11, armpl_int_t ldx11, double *x12,
                           armpl_int_t ldx12, double *x21, armpl_int_t ldx21,
                           double *x22, armpl_int_t ldx22, double *theta,
                           double *u1, armpl_int_t ldu1, double *u2,
                           armpl_int_t ldu2, double *v1t, armpl_int_t ldv1t,
                           double *v2t, armpl_int_t ldv2t);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

                               double *v1t, armpl_int_t ldv1t);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorcsd2by1* and *LAPACKE_sorcsd2by1*. It also exists with a native Fortran interface as *dorcsd2by1*.

4.19.877 LAPACKE_dorcsd2by1_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorcsd2by1_work(armpl_int_t matrix_layout, char jobu1,
                                    char jobu2, char jobv1t, armpl_int_t m,
                                    armpl_int_t p, armpl_int_t q, double *x11,
                                    armpl_int_t ldx11, double *x21,
                                    armpl_int_t ldx21, double *theta,
                                    double *u1, armpl_int_t ldu1, double *u2,
                                    armpl_int_t ldu2, double *v1t,
                                    armpl_int_t ldv1t, double *work,
                                    armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorcsd2by1_work* and *LAPACKE_sorcsd2by1_work*.

4.19.878 LAPACKE_dorcsd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorcsd_work(armpl_int_t matrix_layout, char jobu1,
                                char jobu2, char jobv1t, char jobv2t,
                                char trans, char signs, armpl_int_t m,

                                armpl_int_t ldv1t, double *v2t,
                                armpl_int_t ldv2t, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorcsd_work* and *LAPACKE_sorcsd_work*.

4.19.879 LAPACKE_dorgbr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgbr(armpl_int_t matrix_layout, char vect,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           double *a, armpl_int_t lda, const double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgbr* and *LAPACKE_sorgbr*. It also exists with a native Fortran interface as *dorgbr*.

4.19.880 LAPACKE_dorgbr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgbr_work(armpl_int_t matrix_layout, char vect,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                double *a, armpl_int_t lda, const double *tau,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgbr_work* and *LAPACKE_sorgbr_work*.

4.19.881 LAPACKE_dorghr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorghr(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t ilo, armpl_int_t ihi, double *a,
                           armpl_int_t lda, const double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorghr* and *LAPACKE_sorghr*. It also exists with a native Fortran interface as *dorghr*.

4.19.882 LAPACKE_dorghr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorghr_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi, double *a,
                                armpl_int_t lda, const double *tau,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorghr_work* and *LAPACKE_sorghr_work*.

4.19.883 LAPACKE_dorglq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorglq(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, double *a,
                           armpl_int_t lda, const double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorglq* and *LAPACKE_sorglq*. It also exists with a native Fortran interface as *dorglq*.

4.19.884 LAPACKE_dorglq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorglq_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, double *a,
                                armpl_int_t lda, const double *tau,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorglq_work* and *LAPACKE_sorglq_work*.

4.19.885 LAPACKE_dorgql

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgql(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, double *a,
                           armpl_int_t lda, const double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgql* and *LAPACKE_sorgql*. It also exists with a native Fortran interface as *dorgql*.

4.19.886 LAPACKE_dorgql_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgql_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, double *a,
                                armpl_int_t lda, const double *tau,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgql_work* and *LAPACKE_sorgql_work*.

4.19.887 LAPACKE_dorgqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgqr(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, double *a,
                           armpl_int_t lda, const double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgqr* and *LAPACKE_sorgqr*. It also exists with a native Fortran interface as *dorgqr*.

4.19.888 LAPACKE_dorgqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgqr_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, double *a,
                                armpl_int_t lda, const double *tau,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgqr_work* and *LAPACKE_sorgqr_work*.

4.19.889 LAPACKE_dorgrq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgrq(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, double *a,
                           armpl_int_t lda, const double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgrq* and *LAPACKE_sorgrq*. It also exists with a native Fortran interface as *dorgrq*.

4.19.890 LAPACKE_dorgrq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgrq_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, double *a,
                                armpl_int_t lda, const double *tau,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgrq_work* and *LAPACKE_sorgrq_work*.

4.19.891 LAPACKE_dorgtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgtr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           const double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgtr* and *LAPACKE_sorgtr*. It also exists with a native Fortran interface as *dorgtr*.

4.19.892 LAPACKE_dorgtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dorgtr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                const double *tau, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgtr_work* and *LAPACKE_sorgtr_work*.

4.19.893 LAPACKE_dormbr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormbr(armpl_int_t matrix_layout, char vect, char side,
                           char trans, armpl_int_t m, armpl_int_t n,
                           armpl_int_t k, const double *a, armpl_int_t lda,
                           const double *tau, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormbr* and *LAPACKE_sormbr*. It also exists with a native Fortran interface as *dormbr*.

4.19.894 LAPACKE_dormbr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormbr_work(armpl_int_t matrix_layout, char vect,
                                char side, char trans, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, const double *a,
                                armpl_int_t lda, const double *tau, double *c,
                                armpl_int_t ldc, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormbr_work* and *LAPACKE_sormbr_work*.

4.19.895 LAPACKE_dormhr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormhr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t ilo,
                           armpl_int_t ihi, const double *a, armpl_int_t lda,
                           const double *tau, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormhr* and *LAPACKE_sormhr*. It also exists with a native Fortran interface as *dormhr*.

4.19.896 LAPACKE_dormhr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormhr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi,
                                const double *a, armpl_int_t lda,
                                const double *tau, double *c, armpl_int_t ldc,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormhr_work* and *LAPACKE_sormhr_work*.

4.19.897 LAPACKE_dormlq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormlq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const double *a, armpl_int_t lda,
                           const double *tau, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormlq* and *LAPACKE_sormlq*. It also exists with a native Fortran interface as *dormlq*.

4.19.898 LAPACKE_dormlq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormlq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const double *a,
                                armpl_int_t lda, const double *tau, double *c,
                                armpl_int_t ldc, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormlq_work* and *LAPACKE_sormlq_work*.

4.19.899 LAPACKE_dormql

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormql(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const double *a, armpl_int_t lda,
                           const double *tau, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormql* and *LAPACKE_sormql*. It also exists with a native Fortran interface as *dormql*.

4.19.900 LAPACKE_dormql_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormql_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const double *a,
                                armpl_int_t lda, const double *tau, double *c,
                                armpl_int_t ldc, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormql_work* and *LAPACKE_sormql_work*.

4.19.901 LAPACKE_dormqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormqr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const double *a, armpl_int_t lda,
                           const double *tau, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormqr* and *LAPACKE_sormqr*. It also exists with a native Fortran interface as *dormqr*.

4.19.902 LAPACKE_dormqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormqr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const double *a,
                                armpl_int_t lda, const double *tau, double *c,
                                armpl_int_t ldc, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormqr_work* and *LAPACKE_sormqr_work*.

4.19.903 LAPACKE_dormrq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormrq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const double *a, armpl_int_t lda,
                           const double *tau, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormrq* and *LAPACKE_sormrq*. It also exists with a native Fortran interface as *dormrq*.

4.19.904 LAPACKE_dormrq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormrq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const double *a,
                                armpl_int_t lda, const double *tau, double *c,
                                armpl_int_t ldc, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormrq_work* and *LAPACKE_sormrq_work*.

4.19.905 LAPACKE_dormrz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormrz(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           armpl_int_t l, const double *a, armpl_int_t lda,
                           const double *tau, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormrz* and *LAPACKE_sormrz*. It also exists with a native Fortran interface as *dormrz*.

4.19.906 LAPACKE_dormrz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormrz_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, armpl_int_t l, const double *a,
                                armpl_int_t lda, const double *tau, double *c,
                                armpl_int_t ldc, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormrz_work* and *LAPACKE_sormrz_work*.

4.19.907 LAPACKE_dormtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormtr(armpl_int_t matrix_layout, char side, char uplo,
                           char trans, armpl_int_t m, armpl_int_t n,
                           const double *a, armpl_int_t lda,
                           const double *tau, double *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormtr* and *LAPACKE_sormtr*. It also exists with a native Fortran interface as *dormtr*.

4.19.908 LAPACKE_dormtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dormtr_work(armpl_int_t matrix_layout, char side,
                                char uplo, char trans, armpl_int_t m,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, const double *tau, double *c,
                                armpl_int_t ldc, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormtr_work* and *LAPACKE_sormtr_work*.

4.19.909 LAPACKE_dpbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, const double *ab,
                           armpl_int_t ldab, double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbcon*, *LAPACKE_dpbcon*, *LAPACKE_spbcon* and *LAPACKE_zpbcon*. It also exists with a native Fortran interface as *dpbcon*.

4.19.910 LAPACKE_dpbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                const double *ab, armpl_int_t ldab,
                                double anorm, double *rcond, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbcon_work*, *LAPACKE_dpbcon_work*, *LAPACKE_spbcon_work* and *LAPACKE_zpbcon_work*.

4.19.911 LAPACKE_dpbequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbequ(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, const double *ab,
                           armpl_int_t ldab, double *s, double *scond,
                           double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbequ*, *LAPACKE_dpbequ*, *LAPACKE_spbequ* and *LAPACKE_zpbequ*. It also exists with a native Fortran interface as *dpbequ*.

4.19.912 LAPACKE_dpbequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbequ_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                const double *ab, armpl_int_t ldab, double *s,
                                double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbequ_work*, *LAPACKE_dpbequ_work*, *LAPACKE_spbequ_work* and *LAPACKE_zpbequ_work*.

4.19.913 LAPACKE_dpbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           const double *ab, armpl_int_t ldab,
                           const double *afb, armpl_int_t ldafb,
                           const double *b, armpl_int_t ldb, double *x,
                           armpl_int_t ldx, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbrfs*, *LAPACKE_dpbrfs*, *LAPACKE_spbrfs* and *LAPACKE_zpbrfs*. It also exists with a native Fortran interface as *dpbrfs*.

4.19.914 LAPACKE_dpbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs, const double *ab,
                                armpl_int_t ldab, const double *afb,
                                armpl_int_t ldafb, const double *b,
                                armpl_int_t ldb, double *x, armpl_int_t ldx,
                                double *ferr, double *berr, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbrfs_work*, *LAPACKE_dpbrfs_work*, *LAPACKE_spbrfs_work* and *LAPACKE_zpbrfs_work*.

4.19.915 LAPACKE_dpbstf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbstf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kb, double *bb,
                           armpl_int_t ldbb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbstf*, *LAPACKE_dpbstf*, *LAPACKE_spbstf* and *LAPACKE_zpbstf*. It also exists with a native Fortran interface as *dpbstf*.

4.19.916 LAPACKE_dpbstf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbstf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kb, double *bb,
                                armpl_int_t ldbb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.917 LAPACKE_dpbsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t kd, armpl_int_t nrhs, double *ab,
                          armpl_int_t ldab, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsv*, *LAPACKE_dpbsv*, *LAPACKE_spbsv* and *LAPACKE_zpbsv*. It also exists with a native Fortran interface as *dpbsv*.

4.19.918 LAPACKE_dpbsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t kd,
                               armpl_int_t nrhs, double *ab, armpl_int_t ldab,
                               double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.919 LAPACKE_dpbsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           double *ab, armpl_int_t ldab, double *afb,
                           armpl_int_t ldafb, char *equed, double *s,
                           double *b, armpl_int_t ldb, double *x,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsvx*, *LAPACKE_dpbsvx*, *LAPACKE_spbsvx* and *LAPACKE_zpbsvx*. It also exists with a native Fortran interface as *dpbsvx*.

4.19.920 LAPACKE_dpbsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs, double *ab,
                                armpl_int_t ldab, double *afb,
                                armpl_int_t ldafb, char *equed, double *s,
                                double *b, armpl_int_t ldb, double *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.921 LAPACKE_dpbtrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbtrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, double *ab,
                           armpl_int_t ldab);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrf*, *LAPACKE_dpbtrf*, *LAPACKE_spbtrf* and *LAPACKE_zpbtrf*. It also exists with a native Fortran interface as *dpbtrf*.

4.19.922 LAPACKE_dpbtrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbtrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd, double *ab,
                                armpl_int_t ldab);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrf_work*, *LAPACKE_dpbtrf_work*, *LAPACKE_spbtrf_work* and *LAPACKE_zpbtrf_work*.

4.19.923 LAPACKE_dpbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbtrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           const double *ab, armpl_int_t ldab, double *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrs*, *LAPACKE_dpbtrs*, *LAPACKE_spbtrs* and *LAPACKE_zpbtrs*. It also exists with a native Fortran interface as *dpbtrs*.

4.19.924 LAPACKE_dpbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpbtrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs, const double *ab,
                                armpl_int_t ldab, double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrs_work*, *LAPACKE_dpbtrs_work*, *LAPACKE_spbtrs_work* and *LAPACKE_zpbtrs_work*.

4.19.925 LAPACKE_dpftrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpftrf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, double *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrf*, *LAPACKE_dpftrf*, *LAPACKE_spftrf* and *LAPACKE_zpftrf*. It also exists with a native Fortran interface as *dpftrf*.

4.19.926 LAPACKE_dpftrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpftrf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, double *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrf_work*, *LAPACKE_dpftrf_work*, *LAPACKE_spftrf_work* and *LAPACKE_zpftrf_work*.

4.19.927 LAPACKE_dpftri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpftri(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, double *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftri*, *LAPACKE_dpftri*, *LAPACKE_spftri* and *LAPACKE_zpftri*. It also exists with a native Fortran interface as *dpftri*.

4.19.928 LAPACKE_dpftri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpftri_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, double *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftri_work*, *LAPACKE_dpftri_work*, *LAPACKE_spftri_work* and *LAPACKE_zpftri_work*.

4.19.929 LAPACKE_dpftrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpftrs(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *a,
                           double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrs*, *LAPACKE_dpftrs*, *LAPACKE_spftrs* and *LAPACKE_zpftrs*. It also exists with a native Fortran interface as *dpftrs*.

4.19.930 LAPACKE_dpftrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpftrs_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const double *a, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrs_work*, *LAPACKE_dpftrs_work*, *LAPACKE_spftrs_work* and *LAPACKE_zpftrs_work*.

4.19.931 LAPACKE_dpocon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpocon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const double *a, armpl_int_t lda,
                           double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpocon*, *LAPACKE_dpocon*, *LAPACKE_spocon* and *LAPACKE_zpocon*. It also exists with a native Fortran interface as *dpocon*.

4.19.932 LAPACKE_dpocon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpocon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, double anorm, double *rcond,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpocon_work*, *LAPACKE_dpocon_work*, *LAPACKE_spocon_work* and *LAPACKE_zpocon_work*.

4.19.933 LAPACKE_dpoequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpoequ(armpl_int_t matrix_layout, armpl_int_t n,
                           const double *a, armpl_int_t lda, double *s,
                           double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequ*, *LAPACKE_dpoequ*, *LAPACKE_spoequ* and *LAPACKE_zpoequ*. It also exists with a native Fortran interface as *dpoequ*.

4.19.934 LAPACKE_dpoequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpoequ_work(armpl_int_t matrix_layout, armpl_int_t n,
                                const double *a, armpl_int_t lda, double *s,
                                double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequ_work*, *LAPACKE_dpoequ_work*, *LAPACKE_spoequ_work* and *LAPACKE_zpoequ_work*.

4.19.935 LAPACKE_dpoequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpoequb(armpl_int_t matrix_layout, armpl_int_t n,
                            const double *a, armpl_int_t lda, double *s,
                            double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequb*, *LAPACKE_dpoequb*, *LAPACKE_spoequb* and *LAPACKE_zpoequb*. It also exists with a native Fortran interface as *dpoequb*.

4.19.936 LAPACKE_dpoequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpoequb_work(armpl_int_t matrix_layout, armpl_int_t n,
                                 const double *a, armpl_int_t lda, double *s,
                                 double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequb_work*, *LAPACKE_dpoequb_work*, *LAPACKE_spoequb_work* and *LAPACKE_zpoequb_work*.

4.19.937 LAPACKE_dporfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dporfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *a,
                           armpl_int_t lda, const double *af,
                           armpl_int_t ldaf, const double *b, armpl_int_t ldb,
                           double *x, armpl_int_t ldx, double *ferr,
                           double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfs*, *LAPACKE_dporfs*, *LAPACKE_sporfs* and *LAPACKE_zporfs*. It also exists with a native Fortran interface as *dporfs*.

4.19.938 LAPACKE_dporfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dporfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *a, armpl_int_t lda,
                                const double *af, armpl_int_t ldaf,
                                const double *b, armpl_int_t ldb, double *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfs_work*, *LAPACKE_dporfs_work*, *LAPACKE_sporfs_work* and *LAPACKE_zporfs_work*.

4.19.939 LAPACKE_dporfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dporfsx(armpl_int_t matrix_layout, char uplo, char equed,
                            armpl_int_t n, armpl_int_t nrhs, const double *a,
                            armpl_int_t lda, const double *af,
                            armpl_int_t ldaf, const double *s,
                            const double *b, armpl_int_t ldb, double *x,
                            armpl_int_t ldx, double *rcond, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfsx*, *LAPACKE_dporfsx*, *LAPACKE_sporfsx* and *LAPACKE_zporfsx*. It also exists with a native Fortran interface as *dporfsx*.

4.19.940 LAPACKE_dporfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dporfsx_work(armpl_int_t matrix_layout, char uplo,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const double *a, armpl_int_t lda,
                                 const double *af, armpl_int_t ldaf,
                                 const double *s, const double *b,
                                 armpl_int_t ldb, double *x, armpl_int_t ldx,
                                 double *rcond, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.941 LAPACKE_dposv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dposv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, double *a, armpl_int_t lda,
                          double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposv*, *LAPACKE_dposv*, *LAPACKE_sposv* and *LAPACKE_zposv*. It also exists with a native Fortran interface as *dposv*.

4.19.942 LAPACKE_dposv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dposv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, double *a,
                               armpl_int_t lda, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.943 LAPACKE_dposvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dposvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, double *a,
                           armpl_int_t lda, double *af, armpl_int_t ldaf,
                           char *equed, double *s, double *b, armpl_int_t ldb,
                           double *x, armpl_int_t ldx, double *rcond,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.945 LAPACKE_dposvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dposvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs, double *a,
                            armpl_int_t lda, double *af, armpl_int_t ldaf,
                            char *equed, double *s, double *b,
                            armpl_int_t ldb, double *x, armpl_int_t ldx,
                            double *rcond, double *rpvgrw, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposvxx*, *LAPACKE_dposvxx*, *LAPACKE_sposvxx* and *LAPACKE_zposvxx*. It also exists with a native Fortran interface as *dposvxx*.

4.19.946 LAPACKE_dposvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dposvxx_work(armpl_int_t matrix_layout, char fact,
                                 char uplo, armpl_int_t n, armpl_int_t nrhs,
                                 double *a, armpl_int_t lda, double *af,
                                 armpl_int_t ldaf, char *equed, double *s,
                                 double *b, armpl_int_t ldb, double *x,
                                 armpl_int_t ldx, double *rcond,
                                 double *rpvgrw, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposvxx_work*, *LAPACKE_dposvxx_work*, *LAPACKE_sposvxx_work* and *LAPACKE_zposvxx_work*.

4.19.947 LAPACKE_dpotrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpotrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf*, *LAPACKE_dpotrf*, *LAPACKE_spotrf* and *LAPACKE_zpotrf*. It also exists with a native Fortran interface as *dpotrf*.

4.19.948 LAPACKE_dpotrf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpotrf2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf2*, *LAPACKE_dpotrf2*, *LAPACKE_spotrf2* and *LAPACKE_zpotrf2*. It also exists with a native Fortran interface as *dpotrf2*.

4.19.949 LAPACKE_dpotrf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpotrf2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf2_work*, *LAPACKE_dpotrf2_work*, *LAPACKE_spotrf2_work* and *LAPACKE_zpotrf2_work*.

4.19.950 LAPACKE_dpotrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpotrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf_work*, *LAPACKE_dpotrf_work*, *LAPACKE_spotrf_work* and *LAPACKE_zpotrf_work*.

4.19.951 LAPACKE_dpotri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpotri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotri*, *LAPACKE_dpotri*, *LAPACKE_spotri* and *LAPACKE_zpotri*. It also exists with a native Fortran interface as *dpotri*.

4.19.952 LAPACKE_dpotri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpotri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotri_work*, *LAPACKE_dpotri_work*, *LAPACKE_spotri_work* and *LAPACKE_zpotri_work*.

4.19.953 LAPACKE_dpotrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpotrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrs*, *LAPACKE_dpotrs*, *LAPACKE_spotrs* and *LAPACKE_zpotrs*. It also exists with a native Fortran interface as *dpotrs*.

4.19.954 LAPACKE_dpotrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpotrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *a, armpl_int_t lda, double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrs_work*, *LAPACKE_dpotrs_work*, *LAPACKE_spotrs_work* and *LAPACKE_zpotrs_work*.

4.19.955 LAPACKE_dppcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dppcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const double *ap, double anorm,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppcon*, *LAPACKE_dppcon*, *LAPACKE_sppcon* and *LAPACKE_zppcon*. It also exists with a native Fortran interface as *dppcon*.

4.19.956 LAPACKE_dppcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dppcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const double *ap, double anorm,
                                double *rcond, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppcon_work*, *LAPACKE_dppcon_work*, *LAPACKE_sppcon_work* and *LAPACKE_zppcon_work*.

4.19.957 LAPACKE_dppequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dppequ(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const double *ap, double *s,
                           double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppequ*, *LAPACKE_dppequ*, *LAPACKE_sppequ* and *LAPACKE_zppequ*. It also exists with a native Fortran interface as *dppequ*.

4.19.958 LAPACKE_dppequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dppequ_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const double *ap, double *s,
                                double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppequ_work*, *LAPACKE_dppequ_work*, *LAPACKE_sppequ_work* and *LAPACKE_zppequ_work*.

4.19.959 LAPACKE_dpprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *ap,
                           const double *afp, const double *b,
                           armpl_int_t ldb, double *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpprfs*, *LAPACKE_dpprfs*, *LAPACKE_spprfs* and *LAPACKE_zpprfs*. It also exists with a native Fortran interface as *dpprfs*.

4.19.960 LAPACKE_dpprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *ap, const double *afp,
                                const double *b, armpl_int_t ldb, double *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpprfs_work*, *LAPACKE_dpprfs_work*, *LAPACKE_spprfs_work* and *LAPACKE_zpprfs_work*.

4.19.961 LAPACKE_dppsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dppsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, double *ap, double *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsv*, *LAPACKE_dppsv*, *LAPACKE_sppsv* and *LAPACKE_zppsv*. It also exists with a native Fortran interface as *dppsv*.

4.19.962 LAPACKE_dppsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dppsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, double *ap,
                               double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsv_work*, *LAPACKE_dppsv_work*, *LAPACKE_sppsv_work* and *LAPACKE_zppsv_work*.

4.19.963 LAPACKE_dppsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dppsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, double *ap,
                           double *afp, char *equed, double *s, double *b,
                           armpl_int_t ldb, double *x, armpl_int_t ldx,
                           double *rcond, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsvx*, *LAPACKE_dppsvx*, *LAPACKE_sppsvx* and *LAPACKE_zppsvx*. It also exists with a native Fortran interface as *dppsvx*.

4.19.964 LAPACKE_dppsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dppsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                double *ap, double *afp, char *equed,
                                double *s, double *b, armpl_int_t ldb,
                                double *x, armpl_int_t ldx, double *rcond,
                                double *ferr, double *berr, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsvx_work*, *LAPACKE_dppsvx_work*, *LAPACKE_sppsvx_work* and *LAPACKE_zppsvx_work*.

4.19.965 LAPACKE_dpptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrf*, *LAPACKE_dpptrf*, *LAPACKE_spptrf* and *LAPACKE_zpptrf*. It also exists with a native Fortran interface as *dpptrf*.

4.19.966 LAPACKE_dpptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrf_work*, *LAPACKE_dpptrf_work*, *LAPACKE_spptrf_work* and *LAPACKE_zpptrf_work*.

4.19.967 LAPACKE_dpptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptri*, *LAPACKE_dpptri*, *LAPACKE_spptri* and *LAPACKE_zpptri*. It also exists with a native Fortran interface as *dpptri*.

4.19.968 LAPACKE_dpptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptri_work*, *LAPACKE_dpptri_work*, *LAPACKE_spptri_work* and *LAPACKE_zpptri_work*.

4.19.969 LAPACKE_dpptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *ap,
                           double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrs*, *LAPACKE_dpptrs*, *LAPACKE_spptrs* and *LAPACKE_zpptrs*. It also exists with a native Fortran interface as *dpptrs*.

4.19.970 LAPACKE_dpptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *ap, double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrs_work*, *LAPACKE_dpptrs_work*, *LAPACKE_spptrs_work* and *LAPACKE_zpptrs_work*.

4.19.971 LAPACKE_dpstrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpstrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           armpl_int_t *piv, armpl_int_t *rank, double tol);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpstrf*, *LAPACKE_dpstrf*, *LAPACKE_spstrf* and *LAPACKE_zpstrf*. It also exists with a native Fortran interface as *dpstrf*.

4.19.972 LAPACKE_dpstrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpstrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                armpl_int_t *piv, armpl_int_t *rank,
                                double tol, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpstrf_work*, *LAPACKE_dpstrf_work*, *LAPACKE_spstrf_work* and *LAPACKE_zpstrf_work*.

4.19.973 LAPACKE_dptcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dptcon(armpl_int_t n, const double *d, const double *e,
                           double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.974 LAPACKE_dptcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dptcon_work(armpl_int_t n, const double *d,
                                const double *e, double anorm, double *rcond,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptcon_work*, *LAPACKE_dptcon_work*, *LAPACKE_sptcon_work* and *LAPACKE_zptcon_work*.

4.19.975 LAPACKE_dpteqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpteqr(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, double *d, double *e, double *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpteqr*, *LAPACKE_dpteqr*, *LAPACKE_spteqr* and *LAPACKE_zpteqr*. It also exists with a native Fortran interface as *dpteqr*.

4.19.976 LAPACKE_dpteqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpteqr_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, double *d, double *e,
                                double *z, armpl_int_t ldz, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpteqr_work*, *LAPACKE_dpteqr_work*, *LAPACKE_spteqr_work* and *LAPACKE_zpteqr_work*.

4.19.977 LAPACKE_dptrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dptrfs(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t nrhs, const double *d, const double *e,
                           const double *df, const double *ef,
                           const double *b, armpl_int_t ldb, double *x,
                           armpl_int_t ldx, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptrfs*, *LAPACKE_dptrfs*, *LAPACKE_sptrfs* and *LAPACKE_zptrfs*. It also exists with a native Fortran interface as *dptrfs*.

4.19.978 LAPACKE_dptrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dptrfs_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t nrhs, const double *d,
                                const double *e, const double *df,
                                const double *ef, const double *b,
                                armpl_int_t ldb, double *x, armpl_int_t ldx,
                                double *ferr, double *berr, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptrfs_work*, *LAPACKE_dptrfs_work*, *LAPACKE_sptrfs_work* and *LAPACKE_zptrfs_work*.

4.19.979 LAPACKE_dptsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dptsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, double *d, double *e, double *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsv*, *LAPACKE_dptsv*, *LAPACKE_sptsv* and *LAPACKE_zptsv*. It also exists with a native Fortran interface as *dptsv*.

4.19.980 LAPACKE_dptsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dptsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, double *d, double *e,
                               double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsv_work*, *LAPACKE_dptsv_work*, *LAPACKE_sptsv_work* and *LAPACKE_zptsv_work*.

4.19.981 LAPACKE_dptsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dptsvx(armpl_int_t matrix_layout, char fact,
                           armpl_int_t n, armpl_int_t nrhs, const double *d,
                           const double *e, double *df, double *ef,
                           const double *b, armpl_int_t ldb, double *x,
                           armpl_int_t ldx, double *rcond, double *ferr,
                           double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsvx*, *LAPACKE_dptsvx*, *LAPACKE_sptsvx* and *LAPACKE_zptsvx*. It also exists with a native Fortran interface as *dptsvx*.

4.19.982 LAPACKE_dptsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dptsvx_work(armpl_int_t matrix_layout, char fact,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *d, const double *e, double *df,
                                double *ef, const double *b, armpl_int_t ldb,
                                double *x, armpl_int_t ldx, double *rcond,
                                double *ferr, double *berr, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsvx_work*, *LAPACKE_dptsvx_work*, *LAPACKE_sptsvx_work* and *LAPACKE_zptsvx_work*.

4.19.983 LAPACKE_dpttrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpttrf(armpl_int_t n, double *d, double *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrf*, *LAPACKE_dpttrf*, *LAPACKE_spttrf* and *LAPACKE_zpttrf*. It also exists with a native Fortran interface as *dpttrf*.

4.19.984 LAPACKE_dpttrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpttrf_work(armpl_int_t n, double *d, double *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrf_work*, *LAPACKE_dpttrf_work*, *LAPACKE_spttrf_work* and *LAPACKE_zpttrf_work*.

4.19.985 LAPACKE_dpttrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpttrs(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t nrhs, const double *d, const double *e,
                           double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrs*, *LAPACKE_dpttrs*, *LAPACKE_spttrs* and *LAPACKE_zpttrs*. It also exists with a native Fortran interface as *dpttrs*.

4.19.986 LAPACKE_dpttrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dpttrs_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t nrhs, const double *d,
                                const double *e, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrs_work*, *LAPACKE_dpttrs_work*, *LAPACKE_spttrs_work* and *LAPACKE_zpttrs_work*.

4.19.987 LAPACKE_dsbev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_int_t kd, double *ab,
                          armpl_int_t ldab, double *w, double *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbev* and *LAPACKE_ssbev*. It also exists with a native Fortran interface as *dsbev*.

4.19.988 LAPACKE_dsbev_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbev_2stage(armpl_int_t matrix_layout, char jobz,
                                 char uplo, armpl_int_t n, armpl_int_t kd,
                                 double *ab, armpl_int_t ldab, double *w,
                                 double *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbev_2stage* and *LAPACKE_ssbev_2stage*. It also exists with a native Fortran interface as *dsbev_2stage*.

4.19.989 LAPACKE_dsbev_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbev_2stage_work(armpl_int_t matrix_layout, char jobz,
                                      char uplo, armpl_int_t n,
                                      armpl_int_t kd, double *ab,
                                      armpl_int_t ldab, double *w, double *z,
                                      armpl_int_t ldz, double *work,
                                      armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbev_2stage_work* and *LAPACKE_ssbev_2stage_work*.

4.19.990 LAPACKE_dsbev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, armpl_int_t kd,
                               double *ab, armpl_int_t ldab, double *w,
                               double *z, armpl_int_t ldz, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbev_work* and *LAPACKE_ssbev_work*.

4.19.991 LAPACKE_dsbevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_int_t kd, double *ab,
                           armpl_int_t ldab, double *w, double *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevd* and *LAPACKE_ssbevd*. It also exists with a native Fortran interface as *dsbevd*.

4.19.992 LAPACKE_dsbevd_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbevd_2stage(armpl_int_t matrix_layout, char jobz,
                                  char uplo, armpl_int_t n, armpl_int_t kd,
                                  double *ab, armpl_int_t ldab, double *w,
                                  double *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevd_2stage* and *LAPACKE_ssbevd_2stage*. It also exists with a native Fortran interface as *dsbevd_2stage*.

4.19.993 LAPACKE_dsbevd_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbevd_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char uplo, armpl_int_t n,
                                       armpl_int_t kd, double *ab,
                                       armpl_int_t ldab, double *w, double *z,
                                       armpl_int_t ldz, double *work,
                                       armpl_int_t lwork, armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevd_2stage_work* and *LAPACKE_ssbevd_2stage_work*.

4.19.994 LAPACKE_dsbevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                double *ab, armpl_int_t ldab, double *w,
                                double *z, armpl_int_t ldz, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevd_work* and *LAPACKE_ssbevd_work*.

4.19.995 LAPACKE_dsbevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_int_t kd,
                           double *ab, armpl_int_t ldab, double *q,
                           armpl_int_t ldq, double vl, double vu,
                           armpl_int_t il, armpl_int_t iu, double abstol,
                           armpl_int_t *m, double *w, double *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevx* and *LAPACKE_ssbevx*. It also exists with a native Fortran interface as *dsbevx*.

4.19.996 LAPACKE_dsbevx_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbevx_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  armpl_int_t kd, double *ab,
                                  armpl_int_t ldab, double *q,
                                  armpl_int_t ldq, double vl, double vu,
                                  armpl_int_t il, armpl_int_t iu,
                                  double abstol, armpl_int_t *m, double *w,
                                  double *z, armpl_int_t ldz,
                                  armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevx_2stage* and *LAPACKE_ssbevx_2stage*. It also exists with a native Fortran interface as *dsbevx_2stage*.

4.19.997 LAPACKE_dsbevx_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbevx_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       armpl_int_t kd, double *ab,
                                       armpl_int_t ldab, double *q,
                                       armpl_int_t ldq, double vl, double vu,
                                       armpl_int_t il, armpl_int_t iu,

```

(continues on next page)

(continued from previous page)

```
                                        double *w, double *z, armpl_int_t ldz,
                                        double *work, armpl_int_t lwork,
                                        armpl_int_t *iwork,
                                        armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevx_2stage_work* and *LAPACKE_ssbevx_2stage_work*.

4.19.998 LAPACKE_dsbevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_int_t kd, double *ab, armpl_int_t ldab,
                                double *q, armpl_int_t ldq, double vl,
                                double vu, armpl_int_t il, armpl_int_t iu,
                                double abstol, armpl_int_t *m, double *w,
                                double *z, armpl_int_t ldz, double *work,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevx_work* and *LAPACKE_ssbevx_work*.

4.19.999 LAPACKE_dsbgst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbgst(armpl_int_t matrix_layout, char vect, char uplo,
                           armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                           double *ab, armpl_int_t ldab, const double *bb,
                           armpl_int_t ldbb, double *x, armpl_int_t ldx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgst* and *LAPACKE_ssbgst*. It also exists with a native Fortran interface as *dsbgst*.

4.19.1000 LAPACKE_dsbgst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbgst_work(armpl_int_t matrix_layout, char vect,
                                char uplo, armpl_int_t n, armpl_int_t ka,
                                armpl_int_t kb, double *ab, armpl_int_t ldab,
                                const double *bb, armpl_int_t ldbb, double *x,
                                armpl_int_t ldx, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgst_work* and *LAPACKE_ssbgst_work*.

4.19.1001 LAPACKE_dsbgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbgv(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                          double *ab, armpl_int_t ldab, double *bb,
                          armpl_int_t ldbb, double *w, double *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgv* and *LAPACKE_ssbgv*. It also exists with a native Fortran interface as *dsbgv*.

4.19.1002 LAPACKE_dsbgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbgv_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, armpl_int_t ka,
                               armpl_int_t kb, double *ab, armpl_int_t ldab,
                               double *bb, armpl_int_t ldbb, double *w,
                               double *z, armpl_int_t ldz, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgv_work* and *LAPACKE_ssbgv_work*.

4.19.1003 LAPACKE_dsbgvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbgvd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                           double *ab, armpl_int_t ldab, double *bb,
                           armpl_int_t ldbb, double *w, double *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgvd* and *LAPACKE_ssbgvd*. It also exists with a native Fortran interface as *dsbgvd*.

4.19.1004 LAPACKE_dsbgvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbgvd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, armpl_int_t ka,
                                armpl_int_t kb, double *ab, armpl_int_t ldab,
                                double *bb, armpl_int_t ldbb, double *w,
                                double *z, armpl_int_t ldz, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1005 LAPACKE_dsbgvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbgvx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_int_t ka,
                           armpl_int_t kb, double *ab, armpl_int_t ldab,
                           double *bb, armpl_int_t ldbb, double *q,
                           armpl_int_t ldq, double vl, double vu,
                           armpl_int_t il, armpl_int_t iu, double abstol,
                           armpl_int_t *m, double *w, double *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgvx* and *LAPACKE_ssbgvx*. It also exists with a native Fortran interface as *dsbgvx*.

4.19.1006 LAPACKE_dsbgvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbgvx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_int_t ka, armpl_int_t kb, double *ab,
                                armpl_int_t ldab, double *bb,
                                armpl_int_t ldbb, double *q, armpl_int_t ldq,
                                double vl, double vu, armpl_int_t il,
                                armpl_int_t iu, double abstol, armpl_int_t *m,
                                double *w, double *z, armpl_int_t ldz,
                                double *work, armpl_int_t *iwork,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgvx_work* and *LAPACKE_ssbgvx_work*.

4.19.1007 LAPACKE_dsbtrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbtrd(armpl_int_t matrix_layout, char vect, char uplo,
                           armpl_int_t n, armpl_int_t kd, double *ab,
                           armpl_int_t ldab, double *d, double *e, double *q,
                           armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbtrd* and *LAPACKE_ssbtrd*. It also exists with a native Fortran interface as *dsbtrd*.

4.19.1008 LAPACKE_dsbtrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsbtrd_work(armpl_int_t matrix_layout, char vect,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                double *ab, armpl_int_t ldab, double *d,
                                double *e, double *q, armpl_int_t ldq,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbtrd_work* and *LAPACKE_ssbtrd_work*.

4.19.1009 LAPACKE_dsfrk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsfrk(armpl_int_t matrix_layout, char transr, char uplo,
                          char trans, armpl_int_t n, armpl_int_t k,
                          double alpha, const double *a, armpl_int_t lda,
                          double beta, double *c);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsfrk* and *LAPACKE_ssfrk*. It also exists with a native Fortran interface as *dsfrk*.

4.19.1010 LAPACKE_dsfrk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsfrk_work(armpl_int_t matrix_layout, char transr,
                               char uplo, char trans, armpl_int_t n,
                               armpl_int_t k, double alpha, const double *a,
                               armpl_int_t lda, double beta, double *c);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsfrk_work* and *LAPACKE_ssfrk_work*.

4.19.1011 LAPACKE_dsgesv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsgesv(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t nrhs, double *a, armpl_int_t lda,
                           armpl_int_t *ipiv, double *b, armpl_int_t ldb,
                           double *x, armpl_int_t ldx, armpl_int_t *iter);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsgesv*. It also exists with a native Fortran interface as *dsgesv*.

4.19.1012 LAPACKE_dsgesv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsgesv_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t nrhs, double *a, armpl_int_t lda,
                                armpl_int_t *ipiv, double *b, armpl_int_t ldb,
                                double *x, armpl_int_t ldx, double *work,
                                float *swork, armpl_int_t *iter);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsgesv_work*.

4.19.1013 LAPACKE_dspcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const double *ap,
                           const armpl_int_t *ipiv, double anorm,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspcon*, *LAPACKE_dspcon*, *LAPACKE_sspcon* and *LAPACKE_zspcon*. It also exists with a native Fortran interface as *dspcon*.

4.19.1014 LAPACKE_dspcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const double *ap,
                                const armpl_int_t *ipiv, double anorm,
                                double *rcond, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspcon_work*, *LAPACKE_dspcon_work*, *LAPACKE_sspcon_work* and *LAPACKE_zspcon_work*.

4.19.1015 LAPACKE_dspev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, double *ap, double *w, double *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspev* and *LAPACKE_sspev*. It also exists with a native Fortran interface as *dspev*.

4.19.1016 LAPACKE_dspev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, double *ap,
                               double *w, double *z, armpl_int_t ldz,
                               double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspev_work* and *LAPACKE_sspev_work*.

4.19.1017 LAPACKE_dspevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, double *ap, double *w, double *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspevd* and *LAPACKE_sspevd*. It also exists with a native Fortran interface as *dspevd*.

4.19.1018 LAPACKE_dspevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, double *ap,
                                double *w, double *z, armpl_int_t ldz,
                                double *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspevd_work* and *LAPACKE_sspevd_work*.

4.19.1019 LAPACKE_dspevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, double *ap, double vl,
                           double vu, armpl_int_t il, armpl_int_t iu,
                           double abstol, armpl_int_t *m, double *w,
                           double *z, armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspevx* and *LAPACKE_sspevx*. It also exists with a native Fortran interface as *dspevx*.

4.19.1020 LAPACKE_dspevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                double *ap, double vl, double vu,
                                armpl_int_t il, armpl_int_t iu, double abstol,
                                armpl_int_t *m, double *w, double *z,
                                armpl_int_t ldz, double *work,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspevx_work* and *LAPACKE_sspevx_work*.

4.19.1021 LAPACKE_dspgst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspgst(armpl_int_t matrix_layout, armpl_int_t itype,
                           char uplo, armpl_int_t n, double *ap,
                           const double *bp);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgst* and *LAPACKE_sspgst*. It also exists with a native Fortran interface as *dspgst*.

4.19.1022 LAPACKE_dspgst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspgst_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char uplo, armpl_int_t n, double *ap,
                                const double *bp);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgst_work* and *LAPACKE_sspgst_work*.

4.19.1023 LAPACKE_dspgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspgv(armpl_int_t matrix_layout, armpl_int_t itype,
                          char jobz, char uplo, armpl_int_t n, double *ap,
                          double *bp, double *w, double *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgv* and *LAPACKE_sspgv*. It also exists with a native Fortran interface as *dspgv*.

4.19.1024 LAPACKE_dspgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspgv_work(armpl_int_t matrix_layout, armpl_int_t itype,
                               char jobz, char uplo, armpl_int_t n,
                               double *ap, double *bp, double *w, double *z,
                               armpl_int_t ldz, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgv_work* and *LAPACKE_sspgv_work*.

4.19.1025 LAPACKE_dspgvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspgvd(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char uplo, armpl_int_t n, double *ap,
                           double *bp, double *w, double *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgvd* and *LAPACKE_sspgvd*. It also exists with a native Fortran interface as *dspgvd*.

4.19.1026 LAPACKE_dspgvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspgvd_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char uplo, armpl_int_t n,
                                double *ap, double *bp, double *w, double *z,
                                armpl_int_t ldz, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgvd_work* and *LAPACKE_sspgvd_work*.

4.19.1027 LAPACKE_dspgvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspgvx(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char range, char uplo, armpl_int_t n,
                           double *ap, double *bp, double vl, double vu,
                           armpl_int_t il, armpl_int_t iu, double abstol,
                           armpl_int_t *m, double *w, double *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgvx* and *LAPACKE_sspgvx*. It also exists with a native Fortran interface as *dspgvx*.

4.19.1028 LAPACKE_dspgvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspgvx_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char range, char uplo,
                                armpl_int_t n, double *ap, double *bp,
                                double vl, double vu, armpl_int_t il,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t iu, double abstol, armpl_int_t *m,
                                double *w, double *z, armpl_int_t ldz,
                                double *work, armpl_int_t *iwork,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgvx_work* and *LAPACKE_sspgvx_work*.

4.19.1029 LAPACKE_dsposv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsposv(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb,
                           double *x, armpl_int_t ldx, armpl_int_t *iter);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsposv*. It also exists with a native Fortran interface as *dsposv*.

4.19.1030 LAPACKE_dsposv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsposv_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs, double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                double *x, armpl_int_t ldx, double *work,
                                float *swork, armpl_int_t *iter);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1031 LAPACKE_dsprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *ap,
                           const double *afp, const armpl_int_t *ipiv,
                           const double *b, armpl_int_t ldb, double *x,
                           armpl_int_t ldx, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csprfs*, *LAPACKE_dsprfs*, *LAPACKE_ssprfs* and *LAPACKE_zsprfs*. It also exists with a native Fortran interface as *dsprfs*.

4.19.1032 LAPACKE_dsprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *ap, const double *afp,
                                const armpl_int_t *ipiv, const double *b,
                                armpl_int_t ldb, double *x, armpl_int_t ldx,
                                double *ferr, double *berr, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csprfs_work*, *LAPACKE_dsprfs_work*, *LAPACKE_ssprfs_work* and *LAPACKE_zsprfs_work*.

4.19.1033 LAPACKE_dspsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, double *ap, armpl_int_t *ipiv,
                          double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsv*, *LAPACKE_dspsv*, *LAPACKE_sspsv* and *LAPACKE_zspsv*. It also exists with a native Fortran interface as *dspsv*.

4.19.1034 LAPACKE_dspsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, double *ap,
                               armpl_int_t *ipiv, double *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsv_work*, *LAPACKE_dspsv_work*, *LAPACKE_sspsv_work* and *LAPACKE_zspsv_work*.

4.19.1035 LAPACKE_dspsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *ap,
                           double *afp, armpl_int_t *ipiv, const double *b,
                           armpl_int_t ldb, double *x, armpl_int_t ldx,
                           double *rcond, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsvx*, *LAPACKE_dspsvx*, *LAPACKE_sspsvx* and *LAPACKE_zspsvx*. It also exists with a native Fortran interface as *dspsvx*.

4.19.1036 LAPACKE_dspsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dspsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const double *ap, double *afp,
                                armpl_int_t *ipiv, const double *b,
                                armpl_int_t ldb, double *x, armpl_int_t ldx,
                                double *rcond, double *ferr, double *berr,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsvx_work*, *LAPACKE_dspsvx_work*, *LAPACKE_sspsvx_work* and *LAPACKE_zspsvx_work*.

4.19.1037 LAPACKE_dsptrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsptrd(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *ap, double *d, double *e,
                           double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsptrd* and *LAPACKE_ssptrd*. It also exists with a native Fortran interface as *dsptrd*.

4.19.1038 LAPACKE_dsptrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsptrd_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *ap, double *d,
                                double *e, double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsptrd_work* and *LAPACKE_ssptrd_work*.

4.19.1039 LAPACKE_dsptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *ap, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrf*, *LAPACKE_dsptrf*, *LAPACKE_ssptrf* and *LAPACKE_zsptrf*. It also exists with a native Fortran interface as *dsptrf*.

4.19.1040 LAPACKE_dsptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *ap,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrf_work*, *LAPACKE_dsptrf_work*, *LAPACKE_ssptrf_work* and *LAPACKE_zsptrf_work*.

4.19.1041 LAPACKE_dsptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *ap,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptri*, *LAPACKE_dsptri*, *LAPACKE_ssptri* and *LAPACKE_zsptri*. It also exists with a native Fortran interface as *dsptri*.

4.19.1042 LAPACKE_dsptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *ap,
                                const armpl_int_t *ipiv, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptri_work*, *LAPACKE_dsptri_work*, *LAPACKE_ssptri_work* and *LAPACKE_zsptri_work*.

4.19.1043 LAPACKE_dsptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *ap,
                           const armpl_int_t *ipiv, double *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrs*, *LAPACKE_dsptrs*, *LAPACKE_ssptrs* and *LAPACKE_zsptrs*. It also exists with a native Fortran interface as *dsptrs*.

4.19.1044 LAPACKE_dsptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *ap, const armpl_int_t *ipiv,
                                double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrs_work*, *LAPACKE_dsptrs_work*, *LAPACKE_ssptrs_work* and *LAPACKE_zsptrs_work*.

4.19.1045 LAPACKE_dstebz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstebz(char range, char order, armpl_int_t n, double vl,
                           double vu, armpl_int_t il, armpl_int_t iu,
                           double abstol, const double *d, const double *e,
                           armpl_int_t *m, armpl_int_t *nsplit, double *w,
                           armpl_int_t *iblock, armpl_int_t *isplit);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstebz* and *LAPACKE_sstebz*. It also exists with a native Fortran interface as *dstebz*.

4.19.1046 LAPACKE_dstebz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstebz_work(char range, char order, armpl_int_t n,
                                double vl, double vu, armpl_int_t il,
                                armpl_int_t iu, double abstol,
                                const double *d, const double *e,
                                armpl_int_t *m, armpl_int_t *nsplit,
                                double *w, armpl_int_t *iblock,
                                armpl_int_t *isplit, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstebz_work* and *LAPACKE_sstebz_work*.

4.19.1047 LAPACKE_dstedc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstedc(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, double *d, double *e, double *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstedc*, *LAPACKE_dstedc*, *LAPACKE_sstedc* and *LAPACKE_zstedc*. It also exists with a native Fortran interface as *dstedc*.

4.19.1048 LAPACKE_dstedc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstedc_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, double *d, double *e,
                                double *z, armpl_int_t ldz, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstedc_work*, *LAPACKE_dstedc_work*, *LAPACKE_sstedc_work* and *LAPACKE_zstedc_work*.

4.19.1049 LAPACKE_dstegr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstegr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, double *d, double *e, double vl,
                           double vu, armpl_int_t il, armpl_int_t iu,
                           double abstol, armpl_int_t *m, double *w,
                           double *z, armpl_int_t ldz, armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstegr*, *LAPACKE_dstegr*, *LAPACKE_sstegr* and *LAPACKE_zstegr*. It also exists with a native Fortran interface as *dstegr*.

4.19.1050 LAPACKE_dstegr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstegr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, double *d,
                                double *e, double vl, double vu,
                                armpl_int_t il, armpl_int_t iu, double abstol,
                                armpl_int_t *m, double *w, double *z,
                                armpl_int_t ldz, armpl_int_t *isuppz,
                                double *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstegr_work*, *LAPACKE_dstegr_work*, *LAPACKE_sstegr_work* and *LAPACKE_zstegr_work*.

4.19.1051 LAPACKE_dstein

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstein(armpl_int_t matrix_layout, armpl_int_t n,
                           const double *d, const double *e, armpl_int_t m,
                           const double *w, const armpl_int_t *iblock,
                           const armpl_int_t *isplit, double *z,
                           armpl_int_t ldz, armpl_int_t *ifailv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstein*, *LAPACKE_dstein*, *LAPACKE_sstein* and *LAPACKE_zstein*. It also exists with a native Fortran interface as *dstein*.

4.19.1052 LAPACKE_dstein_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstein_work(armpl_int_t matrix_layout, armpl_int_t n,
                                const double *d, const double *e,
                                armpl_int_t m, const double *w,
                                const armpl_int_t *iblock,
                                const armpl_int_t *isplit, double *z,
                                armpl_int_t ldz, double *work,
                                armpl_int_t *iwork, armpl_int_t *ifailv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstein_work*, *LAPACKE_dstein_work*, *LAPACKE_sstein_work* and *LAPACKE_zstein_work*.

4.19.1053 LAPACKE_dstemr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstemr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, double *d, double *e, double vl,
                           double vu, armpl_int_t il, armpl_int_t iu,
                           armpl_int_t *m, double *w, double *z,
                           armpl_int_t ldz, armpl_int_t nzc,
                           armpl_int_t *isuppz, armpl_int_t *tryrac);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstemr*, *LAPACKE_dstemr*, *LAPACKE_sstemr* and *LAPACKE_zstemr*. It also exists with a native Fortran interface as *dstemr*.

4.19.1054 LAPACKE_dstemr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstemr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, double *d,
                                double *e, double vl, double vu,
                                armpl_int_t il, armpl_int_t iu,
                                armpl_int_t *m, double *w, double *z,
                                armpl_int_t ldz, armpl_int_t nzc,
                                armpl_int_t *isuppz, armpl_int_t *tryrac,
                                double *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstemr_work*, *LAPACKE_dstemr_work*, *LAPACKE_sstemr_work* and *LAPACKE_zstemr_work*.

4.19.1055 LAPACKE_dsteqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsteqr(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, double *d, double *e, double *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csteqr*, *LAPACKE_dsteqr*, *LAPACKE_ssteqr* and *LAPACKE_zsteqr*. It also exists with a native Fortran interface as *dsteqr*.

4.19.1056 LAPACKE_dsteqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsteqr_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, double *d, double *e,
                                double *z, armpl_int_t ldz, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1057 LAPACKE_dsterf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsterf(armpl_int_t n, double *d, double *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsterf* and *LAPACKE_ssterf*. It also exists with a native Fortran interface as *dsterf*.

4.19.1058 LAPACKE_dsterf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsterf_work(armpl_int_t n, double *d, double *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsterf_work* and *LAPACKE_ssterf_work*.

4.19.1059 LAPACKE_dstev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstev(armpl_int_t matrix_layout, char jobz, armpl_int_t n,
                          double *d, double *e, double *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstev* and *LAPACKE_sstev*. It also exists with a native Fortran interface as *dstev*.

4.19.1060 LAPACKE_dstev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstev_work(armpl_int_t matrix_layout, char jobz,
                               armpl_int_t n, double *d, double *e, double *z,
                               armpl_int_t ldz, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstev_work* and *LAPACKE_sstev_work*.

4.19.1061 LAPACKE_dstevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstevd(armpl_int_t matrix_layout, char jobz,
                           armpl_int_t n, double *d, double *e, double *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevd* and *LAPACKE_sstevd*. It also exists with a native Fortran interface as *dstevd*.

4.19.1062 LAPACKE_dstevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstevd_work(armpl_int_t matrix_layout, char jobz,
                                armpl_int_t n, double *d, double *e,
                                double *z, armpl_int_t ldz, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevd_work* and *LAPACKE_sstevd_work*.

4.19.1063 LAPACKE_dstevr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstevr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, double *d, double *e, double vl,
                           double vu, armpl_int_t il, armpl_int_t iu,
                           double abstol, armpl_int_t *m, double *w,
                           double *z, armpl_int_t ldz, armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevr* and *LAPACKE_sstevr*. It also exists with a native Fortran interface as *dstevr*.

4.19.1064 LAPACKE_dstevr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstevr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, double *d,
                                double *e, double vl, double vu,
                                armpl_int_t il, armpl_int_t iu, double abstol,
                                armpl_int_t *m, double *w, double *z,
                                armpl_int_t ldz, armpl_int_t *isuppz,
                                double *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevr_work* and *LAPACKE_sstevr_work*.

4.19.1065 LAPACKE_dstevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstevx(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, double *d, double *e, double vl,
                           double vu, armpl_int_t il, armpl_int_t iu,
                           double abstol, armpl_int_t *m, double *w,
                           double *z, armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevx* and *LAPACKE_sstevx*. It also exists with a native Fortran interface as *dstevx*.

4.19.1066 LAPACKE_dstevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dstevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, double *d,
                                double *e, double vl, double vu,
                                armpl_int_t il, armpl_int_t iu, double abstol,
                                armpl_int_t *m, double *w, double *z,
                                armpl_int_t ldz, double *work,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevx_work* and *LAPACKE_sstevx_work*.

4.19.1067 LAPACKE_dsycon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsycon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const double *a, armpl_int_t lda,
                           const armpl_int_t *ipiv, double anorm,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon*, *LAPACKE_dsycon*, *LAPACKE_ssycon* and *LAPACKE_zsycon*. It also exists with a native Fortran interface as *dsycon*.

4.19.1068 LAPACKE_dsycon_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsycon_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, const double *a, armpl_int_t lda,
                             const double *e, const armpl_int_t *ipiv,
                             double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_3*, *LAPACKE_dsycon_3*, *LAPACKE_ssycon_3* and *LAPACKE_zsycon_3*. It also exists with a native Fortran interface as *dsycon_3*.

4.19.1069 LAPACKE_dsycon_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsycon_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, const double *a,
                                  armpl_int_t lda, const double *e,
                                  const armpl_int_t *ipiv, double anorm,
                                  double *rcond, double *work,
                                  armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_3_work*, *LAPACKE_dsycon_3_work*, *LAPACKE_ssycon_3_work* and *LAPACKE_zsycon_3_work*.

4.19.1070 LAPACKE_dsycon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsycon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                double anorm, double *rcond, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_work*, *LAPACKE_dsycon_work*, *LAPACKE_ssycon_work* and *LAPACKE_zsycon_work*.

4.19.1071 LAPACKE_dsyconv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyconv(armpl_int_t matrix_layout, char uplo, char way,
                            armpl_int_t n, double *a, armpl_int_t lda,
                            const armpl_int_t *ipiv, double *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyconv*, *LAPACKE_dsyconv*, *LAPACKE_ssyconv* and *LAPACKE_zsyconv*. It also exists with a native Fortran interface as *dsyconv*.

4.19.1072 LAPACKE_dsyconv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyconv_work(armpl_int_t matrix_layout, char uplo,
                                 char way, armpl_int_t n, double *a,
                                 armpl_int_t lda, const armpl_int_t *ipiv,
                                 double *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyconv_work*, *LAPACKE_dsyconv_work*, *LAPACKE_ssyconv_work* and *LAPACKE_zsyconv_work*.

4.19.1073 LAPACKE_dsyequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyequb(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, const double *a, armpl_int_t lda,
                            double *s, double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyequb*, *LAPACKE_dsyequb*, *LAPACKE_ssyequb* and *LAPACKE_zsyequb*. It also exists with a native Fortran interface as *dsyequb*.

4.19.1074 LAPACKE_dsyequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyequb_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, const double *a,
                                 armpl_int_t lda, double *s, double *scond,
                                 double *amax, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyequb_work*, *LAPACKE_dsyequb_work*, *LAPACKE_ssyequb_work* and *LAPACKE_zsyequb_work*.

4.19.1075 LAPACKE_dsyev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, double *a, armpl_int_t lda,
                          double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyev* and *LAPACKE_ssyev*. It also exists with a native Fortran interface as *dsyev*.

4.19.1076 LAPACKE_dsyev_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyev_2stage(armpl_int_t matrix_layout, char jobz,
                                 char uplo, armpl_int_t n, double *a,
                                 armpl_int_t lda, double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyev_2stage* and *LAPACKE_ssyev_2stage*. It also exists with a native Fortran interface as *dsyev_2stage*.

4.19.1077 LAPACKE_dsyev_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyev_2stage_work(armpl_int_t matrix_layout, char jobz,
                                      char uplo, armpl_int_t n, double *a,
                                      armpl_int_t lda, double *w,
                                      double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyev_2stage_work* and *LAPACKE_ssyev_2stage_work*.

4.19.1078 LAPACKE_dsyev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, double *a,
                               armpl_int_t lda, double *w, double *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyev_work* and *LAPACKE_ssyev_work*.

4.19.1079 LAPACKE_dsyevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevd* and *LAPACKE_ssyevd*. It also exists with a native Fortran interface as *dsyevd*.

4.19.1080 LAPACKE_dsyevd_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevd_2stage(armpl_int_t matrix_layout, char jobz,
                                  char uplo, armpl_int_t n, double *a,
                                  armpl_int_t lda, double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevd_2stage* and *LAPACKE_ssyevd_2stage*. It also exists with a native Fortran interface as *dsyevd_2stage*.

4.19.1081 LAPACKE_dsyevd_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevd_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char uplo, armpl_int_t n, double *a,
                                       armpl_int_t lda, double *w,
                                       double *work, armpl_int_t lwork,
                                       armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevd_2stage_work* and *LAPACKE_ssyevd_2stage_work*.

4.19.1082 LAPACKE_dsyevd_work

4.19.1083 LAPACKE_dsyevr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevr(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, double *a,
                           armpl_int_t lda, double vl, double vu,
                           armpl_int_t il, armpl_int_t iu, double abstol,
                           armpl_int_t *m, double *w, double *z,
                           armpl_int_t ldz, armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevr* and *LAPACKE_ssyevr*. It also exists with a native Fortran interface as *dsyevr*.

4.19.1084 LAPACKE_dsyevr_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevr_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  double *a, armpl_int_t lda, double vl,
                                  double vu, armpl_int_t il, armpl_int_t iu,
                                  double abstol, armpl_int_t *m, double *w,
                                  double *z, armpl_int_t ldz,
                                  armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevr_2stage* and *LAPACKE_ssyevr_2stage*. It also exists with a native Fortran interface as *dsyevr_2stage*.

4.19.1085 LAPACKE_dsyevr_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevr_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       double *a, armpl_int_t lda, double vl,
                                       double vu, armpl_int_t il,
                                       armpl_int_t iu, double abstol,
                                       armpl_int_t *m, double *w, double *z,
                                       armpl_int_t ldz, armpl_int_t *isuppz,
                                       double *work, armpl_int_t lwork,
                                       armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevr_2stage_work* and *LAPACKE_ssyevr_2stage_work*.

4.19.1086 LAPACKE_dsyevr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevr_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                double *a, armpl_int_t lda, double vl,
                                double vu, armpl_int_t il, armpl_int_t iu,
                                double abstol, armpl_int_t *m, double *w,
                                double *z, armpl_int_t ldz,
                                armpl_int_t *isuppz, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevr_work* and *LAPACKE_ssyevr_work*.

4.19.1087 LAPACKE_dsyevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, double *a,
                           armpl_int_t lda, double vl, double vu,
                           armpl_int_t il, armpl_int_t iu, double abstol,
                           armpl_int_t *m, double *w, double *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevx* and *LAPACKE_ssyevx*. It also exists with a native Fortran interface as *dsyevx*.

4.19.1088 LAPACKE_dsyevx_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevx_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  double *a, armpl_int_t lda, double vl,
                                  double vu, armpl_int_t il, armpl_int_t iu,
                                  double abstol, armpl_int_t *m, double *w,
                                  double *z, armpl_int_t ldz,
                                  armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevx_2stage* and *LAPACKE_ssyevx_2stage*. It also exists with a native Fortran interface as *dsyevx_2stage*.

4.19.1089 LAPACKE_dsyevx_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevx_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       double *a, armpl_int_t lda, double vl,
                                       double vu, armpl_int_t il,
                                       armpl_int_t iu, double abstol,
                                       armpl_int_t *m, double *w, double *z,
                                       armpl_int_t ldz, double *work,
                                       armpl_int_t lwork, armpl_int_t *iwork,
                                       armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevx_2stage_work* and *LAPACKE_ssyevx_2stage_work*.

4.19.1090 LAPACKE_dsyevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                double *a, armpl_int_t lda, double vl,
                                double vu, armpl_int_t il, armpl_int_t iu,
                                double abstol, armpl_int_t *m, double *w,
                                double *z, armpl_int_t ldz, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevx_work* and *LAPACKE_ssyevx_work*.

4.19.1091 LAPACKE_dsygst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygst(armpl_int_t matrix_layout, armpl_int_t itype,
                           char uplo, armpl_int_t n, double *a,
                           armpl_int_t lda, const double *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygst* and *LAPACKE_ssygst*. It also exists with a native Fortran interface as *dsygst*.

4.19.1092 LAPACKE_dsygst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygst_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char uplo, armpl_int_t n, double *a,
                                armpl_int_t lda, const double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygst_work* and *LAPACKE_ssygst_work*.

4.19.1093 LAPACKE_dsygv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygv(armpl_int_t matrix_layout, armpl_int_t itype,
                          char jobz, char uplo, armpl_int_t n, double *a,
                          armpl_int_t lda, double *b, armpl_int_t ldb,
                          double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygv* and *LAPACKE_ssygv*. It also exists with a native Fortran interface as *dsygv*.

4.19.1094 LAPACKE_dsygv_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygv_2stage(armpl_int_t matrix_layout, armpl_int_t itype,
                                 char jobz, char uplo, armpl_int_t n,
                                 double *a, armpl_int_t lda, double *b,
                                 armpl_int_t ldb, double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygv_2stage* and *LAPACKE_ssygv_2stage*. It also exists with a native Fortran interface as *dsygv_2stage*.

4.19.1095 LAPACKE_dsygv_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygv_2stage_work(armpl_int_t matrix_layout,
                                      armpl_int_t itype, char jobz, char uplo,
                                      armpl_int_t n, double *a,
                                      armpl_int_t lda, double *b,
                                      armpl_int_t ldb, double *w,
                                      double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygv_2stage_work* and *LAPACKE_ssygv_2stage_work*.

4.19.1096 LAPACKE_dsygv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygv_work(armpl_int_t matrix_layout, armpl_int_t itype,
                               char jobz, char uplo, armpl_int_t n, double *a,
                               armpl_int_t lda, double *b, armpl_int_t ldb,
                               double *w, double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygv_work* and *LAPACKE_ssygv_work*.

4.19.1097 LAPACKE_dsygvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygvd(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char uplo, armpl_int_t n, double *a,
                           armpl_int_t lda, double *b, armpl_int_t ldb,
                           double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygvd* and *LAPACKE_ssygvd*. It also exists with a native Fortran interface as *dsygvd*.

4.19.1098 LAPACKE_dsygvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygvd_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char uplo, armpl_int_t n,
                                double *a, armpl_int_t lda, double *b,
                                armpl_int_t ldb, double *w, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygvd_work* and *LAPACKE_ssygvd_work*.

4.19.1099 LAPACKE_dsygvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygvx(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char range, char uplo, armpl_int_t n,
                           double *a, armpl_int_t lda, double *b,
                           armpl_int_t ldb, double vl, double vu,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t il, armpl_int_t iu, double abstol,
                                armpl_int_t *m, double *w, double *z,
                                armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygvx* and *LAPACKE_ssygvx*. It also exists with a native Fortran interface as *dsygvx*.

4.19.1100 LAPACKE_dsygvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsygvx_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char range, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *b, armpl_int_t ldb, double vl,
                                double vu, armpl_int_t il, armpl_int_t iu,
                                double abstol, armpl_int_t *m, double *w,
                                double *z, armpl_int_t ldz, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygvx_work* and *LAPACKE_ssygvx_work*.

4.19.1101 LAPACKE_dsyrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *a,
                           armpl_int_t lda, const double *af,
                           armpl_int_t ldaf, const armpl_int_t *ipiv,
                           const double *b, armpl_int_t ldb, double *x,
                           armpl_int_t ldx, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyrfs*, *LAPACKE_dsyrfs*, *LAPACKE_ssyrfs* and *LAPACKE_zsyrfs*. It also exists with a native Fortran interface as *dsyrfs*.

4.19.1102 LAPACKE_dsyrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *a, armpl_int_t lda,
                                const double *af, armpl_int_t ldaf,
                                const armpl_int_t *ipiv, const double *b,
                                armpl_int_t ldb, double *x, armpl_int_t ldx,
                                double *ferr, double *berr, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyrfs_work*, *LAPACKE_dsyrfs_work*, *LAPACKE_ssyrfs_work* and *LAPACKE_zsyrfs_work*.

4.19.1103 LAPACKE_dsyrfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyrfsx(armpl_int_t matrix_layout, char uplo, char equed,
                            armpl_int_t n, armpl_int_t nrhs, const double *a,
                            armpl_int_t lda, const double *af,
                            armpl_int_t ldaf, const armpl_int_t *ipiv,
                            const double *s, const double *b, armpl_int_t ldb,
                            double *x, armpl_int_t ldx, double *rcond,
                            double *berr, armpl_int_t n_err_bnds,
                            double *err_bnds_norm, double *err_bnds_comp,
                            armpl_int_t nparams, double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyrfsx*, *LAPACKE_dsyrfsx*, *LAPACKE_ssyrfsx* and *LAPACKE_zsyrfsx*. It also exists with a native Fortran interface as *dsyrfsx*.

4.19.1104 LAPACKE_dsyrfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyrfsx_work(armpl_int_t matrix_layout, char uplo,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const double *a, armpl_int_t lda,
                                 const double *af, armpl_int_t ldaf,
                                 const armpl_int_t *ipiv, const double *s,
                                 const double *b, armpl_int_t ldb, double *x,
                                 armpl_int_t ldx, double *rcond, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1105 LAPACKE_dsysv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, double *a, armpl_int_t lda,
                          armpl_int_t *ipiv, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv*, *LAPACKE_dsysv*, *LAPACKE_ssysv* and *LAPACKE_zsysv*. It also exists with a native Fortran interface as *dsysv*.

4.19.1106 LAPACKE_dsysv_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysv_aa(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs, double *a,
                             armpl_int_t lda, armpl_int_t *ipiv, double *b,
                             armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_aa*, *LAPACKE_dsysv_aa*, *LAPACKE_ssysv_aa* and *LAPACKE_zsysv_aa*. It also exists with a native Fortran interface as *dsysv_aa*.

4.19.1107 LAPACKE_dsysv_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysv_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs,
                                    double *a, armpl_int_t lda, double *tb,
                                    armpl_int_t ltb, armpl_int_t *ipiv,
                                    armpl_int_t *ipiv2, double *b,
                                    armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_aa_2stage*, *LAPACKE_dsysv_aa_2stage*, *LAPACKE_ssysv_aa_2stage* and *LAPACKE_zsysv_aa_2stage*. It also exists with a native Fortran interface as *dsysv_aa_2stage*.

4.19.1108 LAPACKE_dsysv_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysv_aa_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs, double *a,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t lda, armpl_int_t *ipiv,
                                double *b, armpl_int_t ldb, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1109 LAPACKE_dsysv_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysv_rk(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs, double *a,
                             armpl_int_t lda, double *e, armpl_int_t *ipiv,
                             double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rk*, *LAPACKE_dsysv_rk*, *LAPACKE_ssysv_rk* and *LAPACKE_zsysv_rk*. It also exists with a native Fortran interface as *dsysv_rk*.

4.19.1110 LAPACKE_dsysv_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysv_rk_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs, double *a,
                                  armpl_int_t lda, double *e,
                                  armpl_int_t *ipiv, double *b,
                                  armpl_int_t ldb, double *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rk_work*, *LAPACKE_dsysv_rk_work*, *LAPACKE_ssysv_rk_work* and *LAPACKE_zsysv_rk_work*.

4.19.1111 LAPACKE_dsysv_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysv_rook(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, double *a,
                               armpl_int_t lda, armpl_int_t *ipiv, double *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rook*, *LAPACKE_dsysv_rook*, *LAPACKE_ssysv_rook* and *LAPACKE_zsysv_rook*. It also exists with a native Fortran interface as *dsysv_rook*.

4.19.1112 LAPACKE_dsysv_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysv_rook_work(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs,
                                    double *a, armpl_int_t lda,
                                    armpl_int_t *ipiv, double *b,
                                    armpl_int_t ldb, double *work,
                                    armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rook_work*, *LAPACKE_dsysv_rook_work*, *LAPACKE_ssysv_rook_work* and *LAPACKE_zsysv_rook_work*.

4.19.1113 LAPACKE_dsysv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, double *a,
                               armpl_int_t lda, armpl_int_t *ipiv, double *b,
                               armpl_int_t ldb, double *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_work*, *LAPACKE_dsysv_work*, *LAPACKE_ssysv_work* and *LAPACKE_zsysv_work*.

4.19.1114 LAPACKE_dsysvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *a,
                           armpl_int_t lda, double *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, const double *b,
                           armpl_int_t ldb, double *x, armpl_int_t ldx,
                           double *rcond, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvx*, *LAPACKE_dsysvx*, *LAPACKE_ssysvx* and *LAPACKE_zsysvx*. It also exists with a native Fortran interface as *dsysvx*.

4.19.1115 LAPACKE_dsysvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const double *a, armpl_int_t lda, double *af,
                                armpl_int_t ldaf, armpl_int_t *ipiv,
                                const double *b, armpl_int_t ldb, double *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, double *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvx_work*, *LAPACKE_dsysvx_work*, *LAPACKE_ssysvx_work* and *LAPACKE_zsysvx_work*.

4.19.1116 LAPACKE_dsysvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsysvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs, double *a,
                            armpl_int_t lda, double *af, armpl_int_t ldaf,

4.19.1118 LAPACKE_dsyswapr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyswapr(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, double *a, armpl_int_t lda,
                             armpl_int_t i1, armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyswapr*, *LAPACKE_dsyswapr*, *LAPACKE_ssyswapr* and *LAPACKE_zsyswapr*. It also exists with a native Fortran interface as *dsyswapr*.

4.19.1119 LAPACKE_dsyswapr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsyswapr_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, double *a, armpl_int_t lda,
                                  armpl_int_t i1, armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyswapr_work*, *LAPACKE_dsyswapr_work*, *LAPACKE_ssyswapr_work* and *LAPACKE_zsyswapr_work*.

4.19.1120 LAPACKE_dsytrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrd(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *d, double *e, double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsytrd* and *LAPACKE_ssytrd*. It also exists with a native Fortran interface as *dsytrd*.

4.19.1121 LAPACKE_dsytrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrd_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *d, double *e, double *tau,
                                double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsytrd_work* and *LAPACKE_ssytrd_work*.

4.19.1122 LAPACKE_dsytrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf*, *LAPACKE_dsytrf*, *LAPACKE_ssytrf* and *LAPACKE_zsytrf*. It also exists with a native Fortran interface as *dsytrf*.

4.19.1123 LAPACKE_dsytrf_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrf_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, double *a, armpl_int_t lda,
                              armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa*, *LAPACKE_dsytrf_aa*, *LAPACKE_ssytrf_aa* and *LAPACKE_zsytrf_aa*. It also exists with a native Fortran interface as *dsytrf_aa*.

4.19.1124 LAPACKE_dsytrf_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrf_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, double *a,
                                     armpl_int_t lda, double *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa_2stage*, *LAPACKE_dsytrf_aa_2stage*, *LAPACKE_ssytrf_aa_2stage* and *LAPACKE_zsytrf_aa_2stage*. It also exists with a native Fortran interface as *dsytrf_aa_2stage*.

4.19.1125 LAPACKE_dsytrf_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrf_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, double *a, armpl_int_t lda,
                                   armpl_int_t *ipiv, double *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa_work*, *LAPACKE_dsytrf_aa_work*, *LAPACKE_ssytrf_aa_work* and *LAPACKE_zsytrf_aa_work*.

4.19.1126 LAPACKE_dsytrf_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrf_rk(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, double *a, armpl_int_t lda,
                              double *e, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rk*, *LAPACKE_dsytrf_rk*, *LAPACKE_ssytrf_rk* and *LAPACKE_zsytrf_rk*. It also exists with a native Fortran interface as *dsytrf_rk*.

4.19.1127 LAPACKE_dsytrf_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrf_rk_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, double *a, armpl_int_t lda,
                                   double *e, armpl_int_t *ipiv, double *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rk_work*, *LAPACKE_dsytrf_rk_work*, *LAPACKE_ssytrf_rk_work* and *LAPACKE_zsytrf_rk_work*.

4.19.1128 LAPACKE_dsytrf_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrf_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rook*, *LAPACKE_dsytrf_rook*, *LAPACKE_ssytrf_rook* and *LAPACKE_zsytrf_rook*. It also exists with a native Fortran interface as *dsytrf_rook*.

4.19.1129 LAPACKE_dsytrf_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrf_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, double *a,
                                     armpl_int_t lda, armpl_int_t *ipiv,
                                     double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rook_work*, *LAPACKE_dsytrf_rook_work*, *LAPACKE_ssytrf_rook_work* and *LAPACKE_zsytrf_rook_work*.

4.19.1130 LAPACKE_dsytrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                armpl_int_t *ipiv, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_work*, *LAPACKE_dsytrf_work*, *LAPACKE_ssytrf_work* and *LAPACKE_zsytrf_work*.

4.19.1131 LAPACKE_dsytri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri*, *LAPACKE_dsytri*, *LAPACKE_ssytri* and *LAPACKE_zsytri*. It also exists with a native Fortran interface as *dsytri*.

4.19.1132 LAPACKE_dsytri2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytri2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, double *a, armpl_int_t lda,
                            const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1133 LAPACKE_dsytri2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytri2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, double *a, armpl_int_t lda,
                                 const armpl_int_t *ipiv, double *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2_work*, *LAPACKE_dsytri2_work*, *LAPACKE_ssytri2_work* and *LAPACKE_zsytri2_work*.

4.19.1134 LAPACKE_dsytri2x

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytri2x(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, double *a, armpl_int_t lda,
                             const armpl_int_t *ipiv, armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2x*, *LAPACKE_dsytri2x*, *LAPACKE_ssytri2x* and *LAPACKE_zsytri2x*. It also exists with a native Fortran interface as *dsytri2x*.

4.19.1135 LAPACKE_dsytri2x_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytri2x_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, double *a, armpl_int_t lda,
                                  const armpl_int_t *ipiv, double *work,
                                  armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2x_work*, *LAPACKE_dsytri2x_work*, *LAPACKE_ssytri2x_work* and *LAPACKE_zsytri2x_work*.

4.19.1136 LAPACKE_dsytri_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytri_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, double *a, armpl_int_t lda,
                             const double *e, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri_3*, *LAPACKE_dsytri_3*, *LAPACKE_ssytri_3* and *LAPACKE_zsytri_3*. It also exists with a native Fortran interface as *dsytri_3*.

4.19.1137 LAPACKE_dsytri_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytri_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, double *a, armpl_int_t lda,
                                  const double *e, const armpl_int_t *ipiv,
                                  double *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri_3_work*, *LAPACKE_dsytri_3_work*, *LAPACKE_ssytri_3_work* and *LAPACKE_zsytri_3_work*.

4.19.1138 LAPACKE_dsytri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri_work*, *LAPACKE_dsytri_work*, *LAPACKE_ssytri_work* and *LAPACKE_zsytri_work*.

4.19.1139 LAPACKE_dsytrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *a,
                           armpl_int_t lda, const armpl_int_t *ipiv,
                           double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs*, *LAPACKE_dsytrs*, *LAPACKE_ssytrs* and *LAPACKE_zsytrs*. It also exists with a native Fortran interface as *dsytrs*.

4.19.1140 LAPACKE_dsytrs2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_int_t nrhs, const double *a,
                            armpl_int_t lda, const armpl_int_t *ipiv,
                            double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs2*, *LAPACKE_dsytrs2*, *LAPACKE_ssytrs2* and *LAPACKE_zsytrs2*. It also exists with a native Fortran interface as *dsytrs2*.

4.19.1141 LAPACKE_dsytrs2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_int_t nrhs,
                                 const double *a, armpl_int_t lda,
                                 const armpl_int_t *ipiv, double *b,
                                 armpl_int_t ldb, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1142 LAPACKE_dsytrs_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs, const double *a,
                             armpl_int_t lda, const double *e,
                             const armpl_int_t *ipiv, double *b,
                             armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_3*, *LAPACKE_dsytrs_3*, *LAPACKE_ssytrs_3* and *LAPACKE_zsytrs_3*. It also exists with a native Fortran interface as *dsytrs_3*.

4.19.1143 LAPACKE_dsytrs_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  const double *a, armpl_int_t lda,
                                  const double *e, const armpl_int_t *ipiv,
                                  double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_3_work*, *LAPACKE_dsytrs_3_work*, *LAPACKE_ssytrs_3_work* and *LAPACKE_zsytrs_3_work*.

4.19.1144 LAPACKE_dsytrs_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_int_t nrhs,
                              const double *a, armpl_int_t lda,
                              const armpl_int_t *ipiv, double *b,
                              armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa*, *LAPACKE_dsytrs_aa*, *LAPACKE_ssytrs_aa* and *LAPACKE_zsytrs_aa*. It also exists with a native Fortran interface as *dsytrs_aa*.

4.19.1145 LAPACKE_dsytrs_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     double *a, armpl_int_t lda, double *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2, double *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa_2stage*, *LAPACKE_dsytrs_aa_2stage*, *LAPACKE_ssytrs_aa_2stage* and *LAPACKE_zsytrs_aa_2stage*. It also exists with a native Fortran interface as *dsytrs_aa_2stage*.

4.19.1146 LAPACKE_dsytrs_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_int_t nrhs,
                                   const double *a, armpl_int_t lda,
                                   const armpl_int_t *ipiv, double *b,
                                   armpl_int_t ldb, double *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa_work*, *LAPACKE_dsytrs_aa_work*, *LAPACKE_ssytrs_aa_work* and *LAPACKE_zsytrs_aa_work*.

4.19.1147 LAPACKE_dsytrs_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_rook*, *LAPACKE_dsytrs_rook*, *LAPACKE_ssytrs_rook* and *LAPACKE_zsytrs_rook*. It also exists with a native Fortran interface as *dsytrs_rook*.

4.19.1148 LAPACKE_dsytrs_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     const double *a, armpl_int_t lda,
                                     const armpl_int_t *ipiv, double *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_rook_work*, *LAPACKE_dsytrs_rook_work*, *LAPACKE_ssytrs_rook_work* and *LAPACKE_zsytrs_rook_work*.

4.19.1149 LAPACKE_dsytrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dsytrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_work*, *LAPACKE_dsytrs_work*, *LAPACKE_ssytrs_work* and *LAPACKE_zsytrs_work*.

4.19.1150 LAPACKE_dtbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtbcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           const double *ab, armpl_int_t ldab,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbcon*, *LAPACKE_dtbcon*, *LAPACKE_stbcon* and *LAPACKE_ztbcon*. It also exists with a native Fortran interface as *dtbcon*.

4.19.1151 LAPACKE_dtbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtbcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                armpl_int_t kd, const double *ab,
                                armpl_int_t ldab, double *rcond, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbcon_work*, *LAPACKE_dtbcon_work*, *LAPACKE_stbcon_work* and *LAPACKE_ztbcon_work*.

4.19.1152 LAPACKE_dtbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtbrfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           armpl_int_t nrhs, const double *ab,
                           armpl_int_t ldab, const double *b, armpl_int_t ldb,
                           const double *x, armpl_int_t ldx, double *ferr,
                           double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbrfs*, *LAPACKE_dtbrfs*, *LAPACKE_stbrfs* and *LAPACKE_ztbrfs*. It also exists with a native Fortran interface as *dtbrfs*.

4.19.1153 LAPACKE_dtbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtbrfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t kd, armpl_int_t nrhs,
                                const double *ab, armpl_int_t ldab,
                                const double *b, armpl_int_t ldb,
                                const double *x, armpl_int_t ldx,
                                double *ferr, double *berr, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbrfs_work*, *LAPACKE_dtbrfs_work*, *LAPACKE_stbrfs_work* and *LAPACKE_ztbrfs_work*.

4.19.1154 LAPACKE_dtbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtbtrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           armpl_int_t nrhs, const double *ab,
                           armpl_int_t ldab, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbtrs*, *LAPACKE_dtbtrs*, *LAPACKE_stbtrs* and *LAPACKE_ztbtrs*. It also exists with a native Fortran interface as *dtbtrs*.

4.19.1155 LAPACKE_dtbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtbtrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t kd, armpl_int_t nrhs,
                                const double *ab, armpl_int_t ldab, double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbtrs_work*, *LAPACKE_dtbtrs_work*, *LAPACKE_stbtrs_work* and *LAPACKE_ztbtrs_work*.

4.19.1156 LAPACKE_dtfsm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtfsm(armpl_int_t matrix_layout, char transr, char side,
                          char uplo, char trans, char diag, armpl_int_t m,
                          armpl_int_t n, double alpha, const double *a,
                          double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfsm*, *LAPACKE_dtfsm*, *LAPACKE_stfsm* and *LAPACKE_ztfsm*. It also exists with a native Fortran interface as *dtfsm*.

4.19.1157 LAPACKE_dtfsm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtfsm_work(armpl_int_t matrix_layout, char transr,
                               char side, char uplo, char trans, char diag,
                               armpl_int_t m, armpl_int_t n, double alpha,
                               const double *a, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfsm_work*, *LAPACKE_dtfsm_work*, *LAPACKE_stfsm_work* and *LAPACKE_ztfsm_work*.

4.19.1158 LAPACKE_dtftri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtftri(armpl_int_t matrix_layout, char transr, char uplo,
                           char diag, armpl_int_t n, double *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctftri*, *LAPACKE_dtftri*, *LAPACKE_stftri* and *LAPACKE_ztftri*. It also exists with a native Fortran interface as *dtftri*.

4.19.1159 LAPACKE_dtftri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtftri_work(armpl_int_t matrix_layout, char transr,
                                char uplo, char diag, armpl_int_t n,
                                double *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctftri_work*, *LAPACKE_dtftri_work*, *LAPACKE_stftri_work* and *LAPACKE_ztftri_work*.

4.19.1160 LAPACKE_dtfttp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtfttp(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const double *arf, double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttp*, *LAPACKE_dtfttp*, *LAPACKE_stfttp* and *LAPACKE_ztfttp*. It also exists with a native Fortran interface as *dtfttp*.

4.19.1161 LAPACKE_dtfttp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtfttp_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, const double *arf,
                                double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttp_work*, *LAPACKE_dtfttp_work*, *LAPACKE_stfttp_work* and *LAPACKE_ztfttp_work*.

4.19.1162 LAPACKE_dtfttr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtfttr(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const double *arf, double *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttr*, *LAPACKE_dtfttr*, *LAPACKE_stfttr* and *LAPACKE_ztfttr*. It also exists with a native Fortran interface as *dtfttr*.

4.19.1163 LAPACKE_dtfttr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtfttr_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, const double *arf,
                                double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttr_work*, *LAPACKE_dtfttr_work*, *LAPACKE_stfttr_work* and *LAPACKE_ztfttr_work*.

4.19.1164 LAPACKE_dtgevc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgevc(armpl_int_t matrix_layout, char side, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const double *s, armpl_int_t lds, const double *p,
                           armpl_int_t ldp, double *vl, armpl_int_t ldvl,
                           double *vr, armpl_int_t ldvr, armpl_int_t mm,
                           armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgevc*, *LAPACKE_dtgevc*, *LAPACKE_stgevc* and *LAPACKE_ztgevc*. It also exists with a native Fortran interface as *dtgevc*.

4.19.1165 LAPACKE_dtgevc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgevc_work(armpl_int_t matrix_layout, char side,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, const double *s,
                                armpl_int_t lds, const double *p,
                                armpl_int_t ldp, double *vl, armpl_int_t ldvl,
                                double *vr, armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgevc_work*, *LAPACKE_dtgevc_work*, *LAPACKE_stgevc_work* and *LAPACKE_ztgevc_work*.

4.19.1166 LAPACKE_dtgexc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgexc(armpl_int_t matrix_layout, armpl_int_t wantq,
                           armpl_int_t wantz, armpl_int_t n, double *a,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                double *q, armpl_int_t ldq, double *z,
                                armpl_int_t ldz, armpl_int_t *ifst,
                                armpl_int_t *ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgexc*, *LAPACKE_dtgexc*, *LAPACKE_stgexc* and *LAPACKE_ztgexc*. It also exists with a native Fortran interface as *dtgexc*.

4.19.1167 LAPACKE_dtgexc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgexc_work(armpl_int_t matrix_layout, armpl_int_t wantq,
                                armpl_int_t wantz, armpl_int_t n, double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb,
                                double *q, armpl_int_t ldq, double *z,
                                armpl_int_t ldz, armpl_int_t *ifst,
                                armpl_int_t *ilst, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgexc_work*, *LAPACKE_dtgexc_work*, *LAPACKE_stgexc_work* and *LAPACKE_ztgexc_work*.

4.19.1168 LAPACKE_dtgsen

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgsen(armpl_int_t matrix_layout, armpl_int_t ijob,
                           armpl_int_t wantq, armpl_int_t wantz,
                           const armpl_int_t *select, armpl_int_t n,
                           double *a, armpl_int_t lda, double *b,
                           armpl_int_t ldb, double *alphar, double *alphai,
                           double *beta, double *q, armpl_int_t ldq,
                           double *z, armpl_int_t ldz, armpl_int_t *m,
                           double *pl, double *pr, double *dif);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsen*, *LAPACKE_dtgsen*, *LAPACKE_stgsen* and *LAPACKE_ztgsen*. It also exists with a native Fortran interface as *dtgsen*.

4.19.1169 LAPACKE_dtgsen_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgsen_work(armpl_int_t matrix_layout, armpl_int_t ijob,
                                armpl_int_t wantq, armpl_int_t wantz,
                                const armpl_int_t *select, armpl_int_t n,
                                double *a, armpl_int_t lda, double *b,
                                armpl_int_t ldb, double *alphar,
                                double *alphai, double *beta, double *q,
                                armpl_int_t ldq, double *z, armpl_int_t ldz,
                                armpl_int_t *m, double *pl, double *pr,
                                double *dif, double *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsen_work*, *LAPACKE_dtgsen_work*, *LAPACKE_stgsen_work* and *LAPACKE_ztgsen_work*.

4.19.1170 LAPACKE_dtgsja

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgsja(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t p,
                           armpl_int_t n, armpl_int_t k, armpl_int_t l,
                           double *a, armpl_int_t lda, double *b,
                           armpl_int_t ldb, double tola, double tolb,
                           double *alpha, double *beta, double *u,
                           armpl_int_t ldu, double *v, armpl_int_t ldv,
                           double *q, armpl_int_t ldq, armpl_int_t *ncycle);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsja*, *LAPACKE_dtgsja*, *LAPACKE_stgsja* and *LAPACKE_ztgsja*. It also exists with a native Fortran interface as *dtgsja*.

4.19.1171 LAPACKE_dtgsja_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgsja_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n, armpl_int_t k,
                                armpl_int_t l, double *a, armpl_int_t lda,
                                double *b, armpl_int_t ldb, double tola,
                                double tolb, double *alpha, double *beta,
                                double *u, armpl_int_t ldu, double *v,
                                armpl_int_t ldv, double *q, armpl_int_t ldq,
                                double *work, armpl_int_t *ncycle);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsja_work*, *LAPACKE_dtgsja_work*, *LAPACKE_stgsja_work* and *LAPACKE_ztgsja_work*.

4.19.1172 LAPACKE_dtgsna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgsna(armpl_int_t matrix_layout, char job, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const double *a, armpl_int_t lda, const double *b,
                           armpl_int_t ldb, const double *vl,
                           armpl_int_t ldvl, const double *vr,
                           armpl_int_t ldvr, double *s, double *dif,
                           armpl_int_t mm, armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsna*, *LAPACKE_dtgsna*, *LAPACKE_stgsna* and *LAPACKE_ztgsna*. It also exists with a native Fortran interface as *dtgsna*.

4.19.1173 LAPACKE_dtgsna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgsna_work(armpl_int_t matrix_layout, char job,
                                char howmny, const armpl_int_t *select,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, const double *b,
                                armpl_int_t ldb, const double *vl,
                                armpl_int_t ldvl, const double *vr,
                                armpl_int_t ldvr, double *s, double *dif,
                                armpl_int_t mm, armpl_int_t *m, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsna_work*, *LAPACKE_dtgsna_work*, *LAPACKE_stgsna_work* and *LAPACKE_ztgsna_work*.

4.19.1174 LAPACKE_dtgsyl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgsyl(armpl_int_t matrix_layout, char trans,
                           armpl_int_t ijob, armpl_int_t m, armpl_int_t n,
                           const double *a, armpl_int_t lda, const double *b,
                           armpl_int_t ldb, double *c, armpl_int_t ldc,
                           const double *d, armpl_int_t ldd, const double *e,
                           armpl_int_t lde, double *f, armpl_int_t ldf,
                           double *scale, double *dif);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsyl*, *LAPACKE_dtgsyl*, *LAPACKE_stgsyl* and *LAPACKE_ztgsyl*. It also exists with a native Fortran interface as *dtgsyl*.

4.19.1175 LAPACKE_dtgsyl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtgsyl_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t ijob, armpl_int_t m,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, const double *b,
                                armpl_int_t ldb, double *c, armpl_int_t ldc,
                                const double *d, armpl_int_t ldd,
                                const double *e, armpl_int_t lde, double *f,
                                armpl_int_t ldf, double *scale, double *dif,
                                double *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsyl_work*, *LAPACKE_dtgsyl_work*, *LAPACKE_stgsyl_work* and *LAPACKE_ztgsyl_work*.

4.19.1176 LAPACKE_dtpcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n, const double *ap,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpcon*, *LAPACKE_dtpcon*, *LAPACKE_stpcon* and *LAPACKE_ztpcon*. It also exists with a native Fortran interface as *dtpcon*.

4.19.1177 LAPACKE_dtpcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                const double *ap, double *rcond, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1178 LAPACKE_dtpmqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpmqrt(armpl_int_t matrix_layout, char side, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t k,
                            armpl_int_t l, armpl_int_t nb, const double *v,
                            armpl_int_t ldv, const double *t, armpl_int_t ldt,
                            double *a, armpl_int_t lda, double *b,
                            armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpmqrt*, *LAPACKE_dtpmqrt*, *LAPACKE_stpmqrt* and *LAPACKE_ztpmqrt*. It also exists with a native Fortran interface as *dtpmqrt*.

4.19.1179 LAPACKE_dtpmqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpmqrt_work(armpl_int_t matrix_layout, char side,
                                 char trans, armpl_int_t m, armpl_int_t n,
                                 armpl_int_t k, armpl_int_t l, armpl_int_t nb,
                                 const double *v, armpl_int_t ldv,
                                 const double *t, armpl_int_t ldt, double *a,
                                 armpl_int_t lda, double *b, armpl_int_t ldb,
                                 double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpmqrt_work*, *LAPACKE_dtpmqrt_work*, *LAPACKE_stpmqrt_work* and *LAPACKE_ztpmqrt_work*.

4.19.1180 LAPACKE_dtpqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpqrt(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t l, armpl_int_t nb,
                           double *a, armpl_int_t lda, double *b,
                           armpl_int_t ldb, double *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt*, *LAPACKE_dtpqrt*, *LAPACKE_stpqrt* and *LAPACKE_ztpqrt*. It also exists with a native Fortran interface as *dtpqrt*.

4.19.1181 LAPACKE_dtpqrt2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpqrt2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_int_t l, double *a,
                            armpl_int_t lda, double *b, armpl_int_t ldb,
                            double *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt2*, *LAPACKE_dtpqrt2*, *LAPACKE_stpqrt2* and *LAPACKE_ztpqrt2*. It also exists with a native Fortran interface as *dtpqrt2*.

4.19.1182 LAPACKE_dtpqrt2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpqrt2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t l, double *a,
                                 armpl_int_t lda, double *b, armpl_int_t ldb,
                                 double *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt2_work*, *LAPACKE_dtpqrt2_work*, *LAPACKE_stpqrt2_work* and *LAPACKE_ztpqrt2_work*.

4.19.1183 LAPACKE_dtpqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpqrt_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t l, armpl_int_t nb,
                                double *a, armpl_int_t lda, double *b,
                                armpl_int_t ldb, double *t, armpl_int_t ldt,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt_work*, *LAPACKE_dtpqrt_work*, *LAPACKE_stpqrt_work* and *LAPACKE_ztpqrt_work*.

4.19.1184 LAPACKE_dtprfb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtprfb(armpl_int_t matrix_layout, char side, char trans,
                           char direct, char storev, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, armpl_int_t l,
                           const double *v, armpl_int_t ldv, const double *t,
                           armpl_int_t ldt, double *a, armpl_int_t lda,
                           double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfb*, *LAPACKE_dtprfb*, *LAPACKE_stprfb* and *LAPACKE_ztprfb*. It also exists with a native Fortran interface as *dtprfb*.

4.19.1185 LAPACKE_dtprfb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtprfb_work(armpl_int_t matrix_layout, char side,
                                char trans, char direct, char storev,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                armpl_int_t l, const double *v,
                                armpl_int_t ldv, const double *t,
                                armpl_int_t ldt, double *a, armpl_int_t lda,
                                double *b, armpl_int_t ldb, double *work,
                                armpl_int_t ldwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfb_work*, *LAPACKE_dtprfb_work*, *LAPACKE_stprfb_work* and *LAPACKE_ztprfb_work*.

4.19.1186 LAPACKE_dtprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtprfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const double *ap, const double *b, armpl_int_t ldb,
                           const double *x, armpl_int_t ldx, double *ferr,
                           double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfs*, *LAPACKE_dtprfs*, *LAPACKE_stprfs* and *LAPACKE_ztprfs*. It also exists with a native Fortran interface as *dtprfs*.

4.19.1187 LAPACKE_dtprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtprfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs, const double *ap,
                                const double *b, armpl_int_t ldb,
                                const double *x, armpl_int_t ldx,
                                double *ferr, double *berr, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfs_work*, *LAPACKE_dtprfs_work*, *LAPACKE_stprfs_work* and *LAPACKE_ztprfs_work*.

4.19.1188 LAPACKE_dtptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtptri(armpl_int_t matrix_layout, char uplo, char diag,
                           armpl_int_t n, double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptri*, *LAPACKE_dtptri*, *LAPACKE_stptri* and *LAPACKE_ztptri*. It also exists with a native Fortran interface as *dtptri*.

4.19.1189 LAPACKE_dtptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtptri_work(armpl_int_t matrix_layout, char uplo,
                                char diag, armpl_int_t n, double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptri_work*, *LAPACKE_dtptri_work*, *LAPACKE_stptri_work* and *LAPACKE_ztptri_work*.

4.19.1190 LAPACKE_dtptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtptrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const double *ap, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptrs*, *LAPACKE_dtptrs*, *LAPACKE_stptrs* and *LAPACKE_ztptrs*. It also exists with a native Fortran interface as *dtptrs*.

4.19.1191 LAPACKE_dtptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtptrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs, const double *ap, double *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptrs_work*, *LAPACKE_dtptrs_work*, *LAPACKE_stptrs_work* and *LAPACKE_ztptrs_work*.

4.19.1192 LAPACKE_dtpttf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpttf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const double *ap, double *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttf*, *LAPACKE_dtpttf*, *LAPACKE_stpttf* and *LAPACKE_ztpttf*. It also exists with a native Fortran interface as *dtpttf*.

4.19.1193 LAPACKE_dtpttf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpttf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, const double *ap,
                                double *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1194 LAPACKE_dtpttr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpttr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const double *ap, double *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttr*, *LAPACKE_dtpttr*, *LAPACKE_stpttr* and *LAPACKE_ztpttr*. It also exists with a native Fortran interface as *dtpttr*.

4.19.1195 LAPACKE_dtpttr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtpttr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const double *ap, double *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttr_work*, *LAPACKE_dtpttr_work*, *LAPACKE_stpttr_work* and *LAPACKE_ztpttr_work*.

4.19.1196 LAPACKE_dtrcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n, const double *a,
                           armpl_int_t lda, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrcon*, *LAPACKE_dtrcon*, *LAPACKE_strcon* and *LAPACKE_ztrcon*. It also exists with a native Fortran interface as *dtrcon*.

4.19.1197 LAPACKE_dtrcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                const double *a, armpl_int_t lda,
                                double *rcond, double *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrcon_work*, *LAPACKE_dtrcon_work*, *LAPACKE_strcon_work* and *LAPACKE_ztrcon_work*.

4.19.1198 LAPACKE_dtrevc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrevc(armpl_int_t matrix_layout, char side, char howmny,
                           armpl_int_t *select, armpl_int_t n,
                           const double *t, armpl_int_t ldt, double *vl,
                           armpl_int_t ldvl, double *vr, armpl_int_t ldvr,
                           armpl_int_t mm, armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrevc*, *LAPACKE_dtrevc*, *LAPACKE_strevc* and *LAPACKE_ztrevc*. It also exists with a native Fortran interface as *dtrevc*.

4.19.1199 LAPACKE_dtrevc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrevc_work(armpl_int_t matrix_layout, char side,
                                char howmny, armpl_int_t *select,
                                armpl_int_t n, const double *t,
                                armpl_int_t ldt, double *vl, armpl_int_t ldvl,
                                double *vr, armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrevc_work*, *LAPACKE_dtrevc_work*, *LAPACKE_strevc_work* and *LAPACKE_ztrevc_work*.

4.19.1200 LAPACKE_dtrexc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrexc(armpl_int_t matrix_layout, char compq,
                           armpl_int_t n, double *t, armpl_int_t ldt,
                           double *q, armpl_int_t ldq, armpl_int_t *ifst,
                           armpl_int_t *ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrexc*, *LAPACKE_dtrexc*, *LAPACKE_strexc* and *LAPACKE_ztrexc*. It also exists with a native Fortran interface as *dtrexc*.

4.19.1201 LAPACKE_dtrexc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrexc_work(armpl_int_t matrix_layout, char compq,
                                armpl_int_t n, double *t, armpl_int_t ldt,
                                double *q, armpl_int_t ldq, armpl_int_t *ifst,
                                armpl_int_t *ilst, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrexc_work*, *LAPACKE_dtrexc_work*, *LAPACKE_strexc_work* and *LAPACKE_ztrexc_work*.

4.19.1202 LAPACKE_dtrrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrrfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const double *a, armpl_int_t lda, const double *b,
                           armpl_int_t ldb, const double *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrrfs*, *LAPACKE_dtrrfs*, *LAPACKE_strrfs* and *LAPACKE_ztrrfs*. It also exists with a native Fortran interface as *dtrrfs*.

4.19.1203 LAPACKE_dtrrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrrfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs, const double *a,
                                armpl_int_t lda, const double *b,
                                armpl_int_t ldb, const double *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                double *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrrfs_work*, *LAPACKE_dtrrfs_work*, *LAPACKE_strrfs_work* and *LAPACKE_ztrrfs_work*.

4.19.1204 LAPACKE_dtrsen

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrsen(armpl_int_t matrix_layout, char job, char compq,
                           const armpl_int_t *select, armpl_int_t n,
                           double *t, armpl_int_t ldt, double *q,
                           armpl_int_t ldq, double *wr, double *wi,
                           armpl_int_t *m, double *s, double *sep);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsen*, *LAPACKE_dtrsen*, *LAPACKE_strsen* and *LAPACKE_ztrsen*. It also exists with a native Fortran interface as *dtrsen*.

4.19.1205 LAPACKE_dtrsen_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrsen_work(armpl_int_t matrix_layout, char job,
                                char compq, const armpl_int_t *select,
                                armpl_int_t n, double *t, armpl_int_t ldt,
                                double *q, armpl_int_t ldq, double *wr,
                                double *wi, armpl_int_t *m, double *s,
                                double *sep, double *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsen_work*, *LAPACKE_dtrsen_work*, *LAPACKE_strsen_work* and *LAPACKE_ztrsen_work*.

4.19.1206 LAPACKE_dtrsna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrsna(armpl_int_t matrix_layout, char job, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const double *t, armpl_int_t ldt, const double *vl,
                           armpl_int_t ldvl, const double *vr,
                           armpl_int_t ldvr, double *s, double *sep,
                           armpl_int_t mm, armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsna*, *LAPACKE_dtrsna*, *LAPACKE_strsna* and *LAPACKE_ztrsna*. It also exists with a native Fortran interface as *dtrsna*.

4.19.1207 LAPACKE_dtrsna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrsna_work(armpl_int_t matrix_layout, char job,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, const double *t,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldt, const double *vl,
                                armpl_int_t ldvl, const double *vr,
                                armpl_int_t ldvr, double *s, double *sep,
                                armpl_int_t mm, armpl_int_t *m, double *work,
                                armpl_int_t ldwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsna_work*, *LAPACKE_dtrsna_work*, *LAPACKE_strsna_work* and *LAPACKE_ztrsna_work*.

4.19.1208 LAPACKE_dtrsyl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrsyl(armpl_int_t matrix_layout, char trana, char tranb,
                           armpl_int_t isgn, armpl_int_t m, armpl_int_t n,
                           const double *a, armpl_int_t lda, const double *b,
                           armpl_int_t ldb, double *c, armpl_int_t ldc,
                           double *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsyl*, *LAPACKE_dtrsyl*, *LAPACKE_strsyl* and *LAPACKE_ztrsyl*. It also exists with a native Fortran interface as *dtrsyl*.

4.19.1209 LAPACKE_dtrsyl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrsyl_work(armpl_int_t matrix_layout, char trana,
                                char tranb, armpl_int_t isgn, armpl_int_t m,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, const double *b,
                                armpl_int_t ldb, double *c, armpl_int_t ldc,
                                double *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsyl_work*, *LAPACKE_dtrsyl_work*, *LAPACKE_strsyl_work* and *LAPACKE_ztrsyl_work*.

4.19.1210 LAPACKE_dtrtri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrtri(armpl_int_t matrix_layout, char uplo, char diag,
                           armpl_int_t n, double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtri*, *LAPACKE_dtrtri*, *LAPACKE_strtri* and *LAPACKE_ztrtri*. It also exists with a native Fortran interface as *dtrtri*.

4.19.1211 LAPACKE_dtrtri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrtri_work(armpl_int_t matrix_layout, char uplo,
                                char diag, armpl_int_t n, double *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtri_work*, *LAPACKE_dtrtri_work*, *LAPACKE_strtri_work* and *LAPACKE_ztrtri_work*.

4.19.1212 LAPACKE_dtrtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrtrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const double *a, armpl_int_t lda, double *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtrs*, *LAPACKE_dtrtrs*, *LAPACKE_strtrs* and *LAPACKE_ztrtrs*. It also exists with a native Fortran interface as *dtrtrs*.

4.19.1213 LAPACKE_dtrtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrtrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs, const double *a,
                                armpl_int_t lda, double *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtrs_work*, *LAPACKE_dtrtrs_work*, *LAPACKE_strtrs_work* and *LAPACKE_ztrtrs_work*.

4.19.1214 LAPACKE_dtrttf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrttf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const double *a, armpl_int_t lda,
                           double *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttf*, *LAPACKE_dtrttf*, *LAPACKE_strttf* and *LAPACKE_ztrttf*. It also exists with a native Fortran interface as *dtrttf*.

4.19.1215 LAPACKE_dtrttf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrttf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, const double *a,
                                armpl_int_t lda, double *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttf_work*, *LAPACKE_dtrttf_work*, *LAPACKE_strttf_work* and *LAPACKE_ztrttf_work*.

4.19.1216 LAPACKE_dtrttp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrttp(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const double *a, armpl_int_t lda,
                           double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttp*, *LAPACKE_dtrttp*, *LAPACKE_strttp* and *LAPACKE_ztrttp*. It also exists with a native Fortran interface as *dtrttp*.

4.19.1217 LAPACKE_dtrttp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtrttp_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda, double *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttp_work*, *LAPACKE_dtrttp_work*, *LAPACKE_strttp_work* and *LAPACKE_ztrttp_work*.

4.19.1218 LAPACKE_dtzrzf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtzrzf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, double *a, armpl_int_t lda,
                           double *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctzrzf*, *LAPACKE_dtzrzf*, *LAPACKE_stzrzf* and *LAPACKE_ztzrzf*. It also exists with a native Fortran interface as *dtzrzf*.

4.19.1219 LAPACKE_dtzrzf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_dtzrzf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, double *a, armpl_int_t lda,
                                double *tau, double *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctzrzf_work*, *LAPACKE_dtzrzf_work*, *LAPACKE_stzrzf_work* and *LAPACKE_ztzrzf_work*.

4.19.1220 LAPACKE_ilaver

Syntax

```
#include "armpl.h"

void LAPACKE_ilaver(armpl_int_t *vers_major, armpl_int_t *vers_minor,
                    armpl_int_t *vers_patch);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1221 LAPACKE_sbbcsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sbbcsd(armpl_int_t matrix_layout, char jobu1, char jobu2,
                           char jobv1t, char jobv2t, char trans,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           float *theta, float *phi, float *u1,
                           armpl_int_t ldu1, float *u2, armpl_int_t ldu2,
                           float *v1t, armpl_int_t ldv1t, float *v2t,
                           armpl_int_t ldv2t, float *b11d, float *b11e,
                           float *b12d, float *b12e, float *b21d, float *b21e,
                           float *b22d, float *b22e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbbcsd*, *LAPACKE_dbbcsd*, *LAPACKE_sbbcsd* and *LAPACKE_zbbcsd*. It also exists with a native Fortran interface as *sbbcsd*.

4.19.1222 LAPACKE_sbbcsd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sbbcsd_work(armpl_int_t matrix_layout, char jobu1,
                                char jobu2, char jobv1t, char jobv2t,
                                char trans, armpl_int_t m, armpl_int_t p,
                                armpl_int_t q, float *theta, float *phi,
                                float *u1, armpl_int_t ldu1, float *u2,

                                armpl_int_t ldv1t, float *v2t,
                                armpl_int_t ldv2t, float *b11d, float *b11e,
                                float *b12d, float *b12e, float *b21d,
                                float *b21e, float *b22d, float *b22e,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbbcsd_work*, *LAPACKE_dbbcsd_work*, *LAPACKE_sbbcsd_work* and *LAPACKE_zbbcsd_work*.

4.19.1223 LAPACKE_sbdsdc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sbdsdc(armpl_int_t matrix_layout, char uplo, char compq,
                           armpl_int_t n, float *d, float *e, float *u,
                           armpl_int_t ldu, float *vt, armpl_int_t ldvt,
                           float *q, armpl_int_t *iq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dbdsdc* and *LAPACKE_sbdsdc*. It also exists with a native Fortran interface as *sbdsdc*.

4.19.1224 LAPACKE_sbdsdc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sbdsdc_work(armpl_int_t matrix_layout, char uplo,
                                char compq, armpl_int_t n, float *d, float *e,
                                float *u, armpl_int_t ldu, float *vt,
                                armpl_int_t ldvt, float *q, armpl_int_t *iq,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dbdsdc_work* and *LAPACKE_sbdsdc_work*.

4.19.1225 LAPACKE_sbdsqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sbdsqr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t ncvt, armpl_int_t nru,
                           armpl_int_t ncc, float *d, float *e, float *vt,
                           armpl_int_t ldvt, float *u, armpl_int_t ldu,
                           float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbdsqr*, *LAPACKE_dbdsqr*, *LAPACKE_sbdsqr* and *LAPACKE_zbdsqr*. It also exists with a native Fortran interface as *sbdsqr*.

4.19.1226 LAPACKE_sbdsqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sbdsqr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t ncvt,
                                armpl_int_t nru, armpl_int_t ncc, float *d,
                                float *e, float *vt, armpl_int_t ldvt,
                                float *u, armpl_int_t ldu, float *c,
                                armpl_int_t ldc, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbdsqr_work*, *LAPACKE_dbdsqr_work*, *LAPACKE_sbdsqr_work* and *LAPACKE_zbdsqr_work*.

4.19.1227 LAPACKE_sbdsvdx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sbdsvdx(armpl_int_t matrix_layout, char uplo, char jobz,
                            char range, armpl_int_t n, float *d, float *e,
                            float vl, float vu, armpl_int_t il,
                            armpl_int_t iu, armpl_int_t *ns, float *s,
                            float *z, armpl_int_t ldz, armpl_int_t *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dbdsvdx* and *LAPACKE_sbdsvdx*. It also exists with a native Fortran interface as *sbdsvdx*.

4.19.1228 LAPACKE_sbdsvdx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sbdsvdx_work(armpl_int_t matrix_layout, char uplo,
                                 char jobz, char range, armpl_int_t n,
                                 float *d, float *e, float vl, float vu,
                                 armpl_int_t il, armpl_int_t iu,
                                 armpl_int_t *ns, float *s, float *z,
                                 armpl_int_t ldz, float *work,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dbdsvdx_work* and *LAPACKE_sbdsvdx_work*.

4.19.1229 LAPACKE_sdisna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sdisna(char job, armpl_int_t m, armpl_int_t n,
                           const float *d, float *sep);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ddisna* and *LAPACKE_sdisna*. It also exists with a native Fortran interface as *sdisna*.

4.19.1230 LAPACKE_sdisna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sdisna_work(char job, armpl_int_t m, armpl_int_t n,
                                const float *d, float *sep);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ddisna_work* and *LAPACKE_sdisna_work*.

4.19.1231 LAPACKE_sgbbrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbbrd(armpl_int_t matrix_layout, char vect,
                           armpl_int_t m, armpl_int_t n, armpl_int_t ncc,
                           armpl_int_t kl, armpl_int_t ku, float *ab,
                           armpl_int_t ldab, float *d, float *e, float *q,
                           armpl_int_t ldq, float *pt, armpl_int_t ldpt,
                           float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbbrd*, *LAPACKE_dgbbrd*, *LAPACKE_sgbbrd* and *LAPACKE_zgbbrd*. It also exists with a native Fortran interface as *sgbbrd*.

4.19.1232 LAPACKE_sgbbrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbbrd_work(armpl_int_t matrix_layout, char vect,
                                armpl_int_t m, armpl_int_t n, armpl_int_t ncc,
                                armpl_int_t kl, armpl_int_t ku, float *ab,
                                armpl_int_t ldab, float *d, float *e,
                                float *q, armpl_int_t ldq, float *pt,
                                armpl_int_t ldpt, float *c, armpl_int_t ldc,
                                float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbbrd_work*, *LAPACKE_dgbbrd_work*, *LAPACKE_sgbbrd_work* and *LAPACKE_zgbbrd_work*.

4.19.1233 LAPACKE_sgbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbcon(armpl_int_t matrix_layout, char norm,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           const float *ab, armpl_int_t ldab,
                           const armpl_int_t *ipiv, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbcon*, *LAPACKE_dgbcon*, *LAPACKE_sgbcon* and *LAPACKE_zgbcon*. It also exists with a native Fortran interface as *sgbcon*.

4.19.1234 LAPACKE_sgbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbcon_work(armpl_int_t matrix_layout, char norm,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                const float *ab, armpl_int_t ldab,
                                const armpl_int_t *ipiv, float anorm,
                                float *rcond, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbcon_work*, *LAPACKE_dgbcon_work*, *LAPACKE_sgbcon_work* and *LAPACKE_zgbcon_work*.

4.19.1235 LAPACKE_sgbequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbequ(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           const float *ab, armpl_int_t ldab, float *r,
                           float *c, float *rowcnd, float *colcnd,
                           float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequ*, *LAPACKE_dgbequ*, *LAPACKE_sgbequ* and *LAPACKE_zgbequ*. It also exists with a native Fortran interface as *sgbequ*.

4.19.1236 LAPACKE_sgbequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbequ_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                const float *ab, armpl_int_t ldab, float *r,
                                float *c, float *rowcnd, float *colcnd,
                                float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequ_work*, *LAPACKE_dgbequ_work*, *LAPACKE_sgbequ_work* and *LAPACKE_zgbequ_work*.

4.19.1237 LAPACKE_sgbequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbequb(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            const float *ab, armpl_int_t ldab, float *r,
                            float *c, float *rowcnd, float *colcnd,
                            float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1238 LAPACKE_sgbequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbequb_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku, const float *ab,
                                 armpl_int_t ldab, float *r, float *c,
                                 float *rowcnd, float *colcnd, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1239 LAPACKE_sgbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbrfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, const float *ab,
                           armpl_int_t ldab, const float *afb,
                           armpl_int_t ldafb, const armpl_int_t *ipiv,
                           const float *b, armpl_int_t ldb, float *x,
                           armpl_int_t ldx, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1240 LAPACKE_sgbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbrfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t nrhs, const float *ab,
                                armpl_int_t ldab, const float *afb,
                                armpl_int_t ldafb, const armpl_int_t *ipiv,
                                const float *b, armpl_int_t ldb, float *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1241 LAPACKE_sgbrfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbrfsx(armpl_int_t matrix_layout, char trans, char equed,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            armpl_int_t nrhs, const float *ab,
                            armpl_int_t ldab, const float *afb,
                            armpl_int_t ldafb, const armpl_int_t *ipiv,
                            const float *r, const float *c, const float *b,
                            armpl_int_t ldb, float *x, armpl_int_t ldx,
                            float *rcond, float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbrfsx*, *LAPACKE_dgbrfsx*, *LAPACKE_sgbrfsx* and *LAPACKE_zgbrfsx*. It also exists with a native Fortran interface as *sgbrfsx*.

4.19.1242 LAPACKE_sgbrfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbrfsx_work(armpl_int_t matrix_layout, char trans,
                                 char equed, armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku, armpl_int_t nrhs,
                                 const float *ab, armpl_int_t ldab,
                                 const float *afb, armpl_int_t ldafb,
                                 const armpl_int_t *ipiv, const float *r,
                                 const float *c, const float *b,
                                 armpl_int_t ldb, float *x, armpl_int_t ldx,
                                 float *rcond, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, float *work,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbrfsx_work*, *LAPACKE_dgbrfsx_work*, *LAPACKE_sgbrfsx_work* and *LAPACKE_zgbrfsx_work*.

4.19.1243 LAPACKE_sgbsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t kl, armpl_int_t ku, armpl_int_t nrhs,
                          float *ab, armpl_int_t ldab, armpl_int_t *ipiv,
                          float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsv*, *LAPACKE_dgbsv*, *LAPACKE_sgbsv* and *LAPACKE_zgbsv*. It also exists with a native Fortran interface as *sgbsv*.

4.19.1244 LAPACKE_sgbsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t kl, armpl_int_t ku,
                               armpl_int_t nrhs, float *ab, armpl_int_t ldab,
                               armpl_int_t *ipiv, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsv_work*, *LAPACKE_dgbsv_work*, *LAPACKE_sgbsv_work* and *LAPACKE_zgbsv_work*.

4.19.1245 LAPACKE_sgbsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbsvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, float *ab, armpl_int_t ldab,
                           float *afb, armpl_int_t ldafb, armpl_int_t *ipiv,
                           char *equed, float *r, float *c, float *b,
                           armpl_int_t ldb, float *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr,
                           float *rpivot);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvx*, *LAPACKE_dgbsvx*, *LAPACKE_sgbsvx* and *LAPACKE_zgbsvx*. It also exists with a native Fortran interface as *sgbsvx*.

4.19.1246 LAPACKE_sgbsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbsvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t kl,
                                armpl_int_t ku, armpl_int_t nrhs, float *ab,
                                armpl_int_t ldab, float *afb,
                                armpl_int_t ldafb, armpl_int_t *ipiv,
                                char *equed, float *r, float *c, float *b,
                                armpl_int_t ldb, float *x, armpl_int_t ldx,
                                float *rcond, float *ferr, float *berr,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvx_work*, *LAPACKE_dgbsvx_work*, *LAPACKE_sgbsvx_work* and *LAPACKE_zgbsvx_work*.

4.19.1247 LAPACKE_sgbsvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbsvxx(armpl_int_t matrix_layout, char fact, char trans,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            armpl_int_t nrhs, float *ab, armpl_int_t ldab,
                            float *afb, armpl_int_t ldafb, armpl_int_t *ipiv,
                            char *equed, float *r, float *c, float *b,
                            armpl_int_t ldb, float *x, armpl_int_t ldx,
                            float *rcond, float *rpvgrw, float *berr,
                            armpl_int_t n_err_bnds, float *err_bnds_norm,
                            float *err_bnds_comp, armpl_int_t nparams,
                            float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvxx*, *LAPACKE_dgbsvxx*, *LAPACKE_sgbsvxx* and *LAPACKE_zgbsvxx*. It also exists with a native Fortran interface as *sgbsvxx*.

4.19.1248 LAPACKE_sgbsvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbsvxx_work(armpl_int_t matrix_layout, char fact,
                                 char trans, armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku, armpl_int_t nrhs, float *ab,
                                 armpl_int_t ldab, float *afb,
                                 armpl_int_t ldafb, armpl_int_t *ipiv,
                                 char *equed, float *r, float *c, float *b,
                                 armpl_int_t ldb, float *x, armpl_int_t ldx,
                                 float *rcond, float *rpvgrw, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, float *work,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvxx_work*, *LAPACKE_dgbsvxx_work*, *LAPACKE_sgbsvxx_work* and *LAPACKE_zgbsvxx_work*.

4.19.1249 LAPACKE_sgbtrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbtrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           float *ab, armpl_int_t ldab, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrf*, *LAPACKE_dgbtrf*, *LAPACKE_sgbtrf* and *LAPACKE_zgbtrf*. It also exists with a native Fortran interface as *sgbtrf*.

4.19.1250 LAPACKE_sgbtrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbtrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                float *ab, armpl_int_t ldab,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrf_work*, *LAPACKE_dgbtrf_work*, *LAPACKE_sgbtrf_work* and *LAPACKE_zgbtrf_work*.

4.19.1251 LAPACKE_sgbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbtrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, const float *ab,
                           armpl_int_t ldab, const armpl_int_t *ipiv,
                           float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrs*, *LAPACKE_dgbtrs*, *LAPACKE_sgbtrs* and *LAPACKE_zgbtrs*. It also exists with a native Fortran interface as *sgbtrs*.

4.19.1252 LAPACKE_sgbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgbtrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                armpl_int_t nrhs, const float *ab,
                                armpl_int_t ldab, const armpl_int_t *ipiv,
                                float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1253 LAPACKE_sgebak

4.19.1254 LAPACKE_sgebak_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgebak_work(armpl_int_t matrix_layout, char job,
                                char side, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, const float *scale,
                                armpl_int_t m, float *v, armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebak_work*, *LAPACKE_dgebak_work*, *LAPACKE_sgebak_work* and *LAPACKE_zgebak_work*.

4.19.1255 LAPACKE_sgebal

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgebal(armpl_int_t matrix_layout, char job, armpl_int_t n,
                           float *a, armpl_int_t lda, armpl_int_t *ilo,
                           armpl_int_t *ihi, float *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebal*, *LAPACKE_dgebal*, *LAPACKE_sgebal* and *LAPACKE_zgebal*. It also exists with a native Fortran interface as *sgebal*.

4.19.1256 LAPACKE_sgebal_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgebal_work(armpl_int_t matrix_layout, char job,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                armpl_int_t *ilo, armpl_int_t *ihi,
                                float *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebal_work*, *LAPACKE_dgebal_work*, *LAPACKE_sgebal_work* and *LAPACKE_zgebal_work*.

4.19.1257 LAPACKE_sgebrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgebrd(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda, float *d,
                           float *e, float *tauq, float *taup);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebrd*, *LAPACKE_dgebrd*, *LAPACKE_sgebrd* and *LAPACKE_zgebrd*. It also exists with a native Fortran interface as *sgebrd*.

4.19.1258 LAPACKE_sgebrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgebrd_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *d, float *e, float *tauq, float *taup,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebrd_work*, *LAPACKE_dgebrd_work*, *LAPACKE_sgebrd_work* and *LAPACKE_zgebrd_work*.

4.19.1259 LAPACKE_sgecon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgecon(armpl_int_t matrix_layout, char norm,
                           armpl_int_t n, const float *a, armpl_int_t lda,
                           float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgecon*, *LAPACKE_dgecon*, *LAPACKE_sgecon* and *LAPACKE_zgecon*. It also exists with a native Fortran interface as *sgecon*.

4.19.1260 LAPACKE_sgecon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgecon_work(armpl_int_t matrix_layout, char norm,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda, float anorm, float *rcond,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgecon_work*, *LAPACKE_dgecon_work*, *LAPACKE_sgecon_work* and *LAPACKE_zgecon_work*.

4.19.1261 LAPACKE_sgeequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeequ(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const float *a, armpl_int_t lda,
                           float *r, float *c, float *rowcnd, float *colcnd,
                           float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequ*, *LAPACKE_dgeequ*, *LAPACKE_sgeequ* and *LAPACKE_zgeequ*. It also exists with a native Fortran interface as *sgeequ*.

4.19.1262 LAPACKE_sgeequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeequ_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda, float *r, float *c,
                                float *rowcnd, float *colcnd, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequ_work*, *LAPACKE_dgeequ_work*, *LAPACKE_sgeequ_work* and *LAPACKE_zgeequ_work*.

4.19.1263 LAPACKE_sgeequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeequb(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, const float *a, armpl_int_t lda,
                            float *r, float *c, float *rowcnd, float *colcnd,
                            float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequb*, *LAPACKE_dgeequb*, *LAPACKE_sgeequb* and *LAPACKE_zgeequb*. It also exists with a native Fortran interface as *sgeequb*.

4.19.1264 LAPACKE_sgeequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeequb_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, const float *a,
                                 armpl_int_t lda, float *r, float *c,
                                 float *rowcnd, float *colcnd, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1265 LAPACKE_sgees

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgees(armpl_int_t matrix_layout, char jobvs, char sort,
                          LAPACK_S_SELECT2 select, armpl_int_t n, float *a,
                          armpl_int_t lda, armpl_int_t *sdim, float *wr,
                          float *wi, float *vs, armpl_int_t ldvs);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgees*, *LAPACKE_dgees*, *LAPACKE_sgees* and *LAPACKE_zgees*. It also exists with a native Fortran interface as *sgees*.

4.19.1266 LAPACKE_sgees_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgees_work(armpl_int_t matrix_layout, char jobvs,
                               char sort, LAPACK_S_SELECT2 select,
                               armpl_int_t n, float *a, armpl_int_t lda,
                               armpl_int_t *sdim, float *wr, float *wi,
                               float *vs, armpl_int_t ldvs, float *work,
                               armpl_int_t lwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgees_work*, *LAPACKE_dgees_work*, *LAPACKE_sgees_work* and *LAPACKE_zgees_work*.

4.19.1267 LAPACKE_sgeesx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeesx(armpl_int_t matrix_layout, char jobvs, char sort,
                           LAPACK_S_SELECT2 select, char sense, armpl_int_t n,
                           float *a, armpl_int_t lda, armpl_int_t *sdim,
```

(continues on next page)

(continued from previous page)

```
                                float *wr, float *wi, float *vs, armpl_int_t ldvs,
                                float *rconde, float *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeesx*, *LAPACKE_dgeesx*, *LAPACKE_sgeesx* and *LAPACKE_zgeesx*. It also exists with a native Fortran interface as *sgeesx*.

4.19.1268 LAPACKE_sgeesx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeesx_work(armpl_int_t matrix_layout, char jobvs,
                                char sort, LAPACK_S_SELECT2 select,
                                char sense, armpl_int_t n, float *a,
                                armpl_int_t lda, armpl_int_t *sdim, float *wr,
                                float *wi, float *vs, armpl_int_t ldvs,
                                float *rconde, float *rcondv, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1269 LAPACKE_sgeev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeev(armpl_int_t matrix_layout, char jobvl, char jobvr,
                          armpl_int_t n, float *a, armpl_int_t lda, float *wr,
                          float *wi, float *vl, armpl_int_t ldvl, float *vr,
                          armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeev*, *LAPACKE_dgeev*, *LAPACKE_sgeev* and *LAPACKE_zgeev*. It also exists with a native Fortran interface as *sgeev*.

4.19.1270 LAPACKE_sgeev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeev_work(armpl_int_t matrix_layout, char jobvl,
                               char jobvr, armpl_int_t n, float *a,
                               armpl_int_t lda, float *wr, float *wi,
                               float *vl, armpl_int_t ldvl, float *vr,
                               armpl_int_t ldvr, float *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeev_work*, *LAPACKE_dgeev_work*, *LAPACKE_sgeev_work* and *LAPACKE_zgeev_work*.

4.19.1271 LAPACKE_sgeevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeevx(armpl_int_t matrix_layout, char balanc, char jobvl,
                           char jobvr, char sense, armpl_int_t n, float *a,
                           armpl_int_t lda, float *wr, float *wi, float *vl,
                           armpl_int_t ldvl, float *vr, armpl_int_t ldvr,
                           armpl_int_t *ilo, armpl_int_t *ihi, float *scale,
                           float *abnrm, float *rconde, float *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeevx*, *LAPACKE_dgeevx*, *LAPACKE_sgeevx* and *LAPACKE_zgeevx*. It also exists with a native Fortran interface as *sgeevx*.

4.19.1272 LAPACKE_sgeevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeevx_work(armpl_int_t matrix_layout, char balanc,
                                char jobvl, char jobvr, char sense,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *wr, float *wi, float *vl,
                                armpl_int_t ldvl, float *vr, armpl_int_t ldvr,
                                armpl_int_t *ilo, armpl_int_t *ihi,
                                float *scale, float *abnrm, float *rconde,
                                float *rcondv, float *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeevx_work*, *LAPACKE_dgeevx_work*, *LAPACKE_sgeevx_work* and *LAPACKE_zgeevx_work*.

4.19.1273 LAPACKE_sgehrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgehrd(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t ilo, armpl_int_t ihi, float *a,
                           armpl_int_t lda, float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgehrd*, *LAPACKE_dgehrd*, *LAPACKE_sgehrd* and *LAPACKE_zgehrd*. It also exists with a native Fortran interface as *sgehrd*.

4.19.1274 LAPACKE_sgehrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgehrd_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi, float *a,
                                armpl_int_t lda, float *tau, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgehrd_work*, *LAPACKE_dgehrd_work*, *LAPACKE_sgehrd_work* and *LAPACKE_zgehrd_work*.

4.19.1275 LAPACKE_sgejsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgejsv(armpl_int_t matrix_layout, char joba, char jobu,
                           char jobv, char jobr, char jobt, char jobp,
                           armpl_int_t m, armpl_int_t n, float *a,
                           armpl_int_t lda, float *sva, float *u,
                           armpl_int_t ldu, float *v, armpl_int_t ldv,
                           float *stat, armpl_int_t *istat);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgejsv*, *LAPACKE_dgejsv*, *LAPACKE_sgejsv* and *LAPACKE_zgejsv*. It also exists with a native Fortran interface as *sgejsv*.

4.19.1276 LAPACKE_sgejsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgejsv_work(armpl_int_t matrix_layout, char joba,
                                char jobu, char jobv, char jobr, char jobt,
                                char jobp, armpl_int_t m, armpl_int_t n,
                                float *a, armpl_int_t lda, float *sva,
                                float *u, armpl_int_t ldu, float *v,
                                armpl_int_t ldv, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgejsv_work*, *LAPACKE_dgejsv_work*, *LAPACKE_sgejsv_work* and *LAPACKE_zgejsv_work*.

4.19.1277 LAPACKE_sgelq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelq(armpl_int_t matrix_layout, armpl_int_t m,
                          armpl_int_t n, float *a, armpl_int_t lda, float *t,
                          armpl_int_t tsize);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq*, *LAPACKE_dgelq*, *LAPACKE_sgelq* and *LAPACKE_zgelq*. It also exists with a native Fortran interface as *sgelq*.

4.19.1278 LAPACKE_sgelq2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelq2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq2*, *LAPACKE_dgelq2*, *LAPACKE_sgelq2* and *LAPACKE_zgelq2*. It also exists with a native Fortran interface as *sgelq2*.

4.19.1279 LAPACKE_sgelq2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelq2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *tau, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq2_work*, *LAPACKE_dgelq2_work*, *LAPACKE_sgelq2_work* and *LAPACKE_zgelq2_work*.

4.19.1280 LAPACKE_sgelq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelq_work(armpl_int_t matrix_layout, armpl_int_t m,
                               armpl_int_t n, float *a, armpl_int_t lda,
                               float *t, armpl_int_t tsize, float *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq_work*, *LAPACKE_dgelq_work*, *LAPACKE_sgelq_work* and *LAPACKE_zgelq_work*.

4.19.1281 LAPACKE_sgelqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelqf*, *LAPACKE_dgelqf*, *LAPACKE_sgelqf* and *LAPACKE_zgelqf*. It also exists with a native Fortran interface as *sgelqf*.

4.19.1282 LAPACKE_sgelqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *tau, float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelqf_work*, *LAPACKE_dgelqf_work*, *LAPACKE_sgelqf_work* and *LAPACKE_zgelqf_work*.

4.19.1283 LAPACKE_sgels

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgels(armpl_int_t matrix_layout, char trans,
                          armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                          float *a, armpl_int_t lda, float *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgels*, *LAPACKE_dgels*, *LAPACKE_sgels* and *LAPACKE_zgels*. It also exists with a native Fortran interface as *sgels*.

4.19.1284 LAPACKE_sgels_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgels_work(armpl_int_t matrix_layout, char trans,
                               armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                               float *a, armpl_int_t lda, float *b,
                               armpl_int_t ldb, float *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgels_work*, *LAPACKE_dgels_work*, *LAPACKE_sgels_work* and *LAPACKE_zgels_work*.

4.19.1285 LAPACKE_sgelsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelsd(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           float *s, float rcond, armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsd*, *LAPACKE_dgelsd*, *LAPACKE_sgelsd* and *LAPACKE_zgelsd*. It also exists with a native Fortran interface as *sgelsd*.

4.19.1286 LAPACKE_sgelsd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelsd_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs, float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                float *s, float rcond, armpl_int_t *rank,
                                float *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsd_work*, *LAPACKE_dgelsd_work*, *LAPACKE_sgelsd_work* and *LAPACKE_zgelsd_work*.

4.19.1287 LAPACKE_sgelss

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelss(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           float *s, float rcond, armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelss*, *LAPACKE_dgelss*, *LAPACKE_sgelss* and *LAPACKE_zgelss*. It also exists with a native Fortran interface as *sgelss*.

4.19.1288 LAPACKE_sgelss_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelss_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs, float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                float *s, float rcond, armpl_int_t *rank,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelss_work*, *LAPACKE_dgelss_work*, *LAPACKE_sgelss_work* and *LAPACKE_zgelss_work*.

4.19.1289 LAPACKE_sgelsy

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelsy(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           armpl_int_t *jpvt, float rcond,
                           armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsy*, *LAPACKE_dgelsy*, *LAPACKE_sgelsy* and *LAPACKE_zgelsy*. It also exists with a native Fortran interface as *sgelsy*.

4.19.1290 LAPACKE_sgelsy_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgelsy_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs, float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                armpl_int_t *jpvt, float rcond,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t *rank, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsy_work*, *LAPACKE_dgelsy_work*, *LAPACKE_sgelsy_work* and *LAPACKE_zgelsy_work*.

4.19.1291 LAPACKE_sgemlq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgemlq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const float *a, armpl_int_t lda, const float *t,
                           armpl_int_t tsize, float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemlq*, *LAPACKE_dgemlq*, *LAPACKE_sgemlq* and *LAPACKE_zgemlq*. It also exists with a native Fortran interface as *sgemlq*.

4.19.1292 LAPACKE_sgemlq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgemlq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const float *a,
                                armpl_int_t lda, const float *t,
                                armpl_int_t tsize, float *c, armpl_int_t ldc,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemlq_work*, *LAPACKE_dgemlq_work*, *LAPACKE_sgemlq_work* and *LAPACKE_zgemlq_work*.

4.19.1293 LAPACKE_sgemqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgemqr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const float *a, armpl_int_t lda, const float *t,
                           armpl_int_t tsize, float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqr*, *LAPACKE_dgemqr*, *LAPACKE_sgemqr* and *LAPACKE_zgemqr*. It also exists with a native Fortran interface as *sgemqr*.

4.19.1294 LAPACKE_sgemqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgemqr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const float *a,
                                armpl_int_t lda, const float *t,
                                armpl_int_t tsize, float *c, armpl_int_t ldc,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqr_work*, *LAPACKE_dgemqr_work*, *LAPACKE_sgemqr_work* and *LAPACKE_zgemqr_work*.

4.19.1295 LAPACKE_sgemqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgemqrt(armpl_int_t matrix_layout, char side, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t k,
                            armpl_int_t nb, const float *v, armpl_int_t ldv,
                            const float *t, armpl_int_t ldt, float *c,
                            armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqrt*, *LAPACKE_dgemqrt*, *LAPACKE_sgemqrt* and *LAPACKE_zgemqrt*. It also exists with a native Fortran interface as *sgemqrt*.

4.19.1296 LAPACKE_sgemqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgemqrt_work(armpl_int_t matrix_layout, char side,
                                 char trans, armpl_int_t m, armpl_int_t n,
                                 armpl_int_t k, armpl_int_t nb,
                                 const float *v, armpl_int_t ldv,
                                 const float *t, armpl_int_t ldt, float *c,
                                 armpl_int_t ldc, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqrt_work*, *LAPACKE_dgemqrt_work*, *LAPACKE_sgemqrt_work* and *LAPACKE_zgemqrt_work*.

4.19.1297 LAPACKE_sgeqlf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqlf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqlf*, *LAPACKE_dgeqlf*, *LAPACKE_sgeqlf* and *LAPACKE_zgeqlf*. It also exists with a native Fortran interface as *sgeqlf*.

4.19.1298 LAPACKE_sgeqlf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqlf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *tau, float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqlf_work*, *LAPACKE_dgeqlf_work*, *LAPACKE_sgeqlf_work* and *LAPACKE_zgeqlf_work*.

4.19.1299 LAPACKE_sgeqp3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqp3(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           armpl_int_t *jpvt, float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqp3*, *LAPACKE_dgeqp3*, *LAPACKE_sgeqp3* and *LAPACKE_zgeqp3*. It also exists with a native Fortran interface as *sgeqp3*.

4.19.1300 LAPACKE_sgeqp3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqp3_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                armpl_int_t *jpvt, float *tau, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqp3_work*, *LAPACKE_dgeqp3_work*, *LAPACKE_sgeqp3_work* and *LAPACKE_zgeqp3_work*.

4.19.1301 LAPACKE_sgeqpf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqpf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           armpl_int_t *jpvt, float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqpf*, *LAPACKE_dgeqpf*, *LAPACKE_sgeqpf* and *LAPACKE_zgeqpf*.

4.19.1302 LAPACKE_sgeqpf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqpf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                armpl_int_t *jpvt, float *tau, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqpf_work*, *LAPACKE_dgeqpf_work*, *LAPACKE_sgeqpf_work* and *LAPACKE_zgeqpf_work*.

4.19.1303 LAPACKE_sgeqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqr(armpl_int_t matrix_layout, armpl_int_t m,
                          armpl_int_t n, float *a, armpl_int_t lda, float *t,
                          armpl_int_t tsize);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr*, *LAPACKE_dgeqr*, *LAPACKE_sgeqr* and *LAPACKE_zgeqr*. It also exists with a native Fortran interface as *sgeqr*.

4.19.1304 LAPACKE_sgeqr2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqr2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr2*, *LAPACKE_dgeqr2*, *LAPACKE_sgeqr2* and *LAPACKE_zgeqr2*. It also exists with a native Fortran interface as *sgeqr2*.

4.19.1305 LAPACKE_sgeqr2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqr2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *tau, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr2_work*, *LAPACKE_dgeqr2_work*, *LAPACKE_sgeqr2_work* and *LAPACKE_zgeqr2_work*.

4.19.1306 LAPACKE_sgeqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqr_work(armpl_int_t matrix_layout, armpl_int_t m,
                               armpl_int_t n, float *a, armpl_int_t lda,
                               float *t, armpl_int_t tsize, float *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr_work*, *LAPACKE_dgeqr_work*, *LAPACKE_sgeqr_work* and *LAPACKE_zgeqr_work*.

4.19.1307 LAPACKE_sgeqrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrf*, *LAPACKE_dgeqrf*, *LAPACKE_sgeqrf* and *LAPACKE_zgeqrf*. It also exists with a native Fortran interface as *sgeqrf*.

4.19.1308 LAPACKE_sgeqrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *tau, float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrf_work*, *LAPACKE_dgeqrf_work*, *LAPACKE_sgeqrf_work* and *LAPACKE_zgeqrf_work*.

4.19.1309 LAPACKE_sgeqrfp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrfp(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, float *a, armpl_int_t lda,
                            float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrfp*, *LAPACKE_dgeqrfp*, *LAPACKE_sgeqrfp* and *LAPACKE_zgeqrfp*. It also exists with a native Fortran interface as *sgeqrfp*.

4.19.1310 LAPACKE_sgeqrfp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrfp_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, float *a, armpl_int_t lda,
                                 float *tau, float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrfp_work*, *LAPACKE_dgeqrfp_work*, *LAPACKE_sgeqrfp_work* and *LAPACKE_zgeqrfp_work*.

4.19.1311 LAPACKE_sgeqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrt(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nb, float *a,
                           armpl_int_t lda, float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt*, *LAPACKE_dgeqrt*, *LAPACKE_sgeqrt* and *LAPACKE_zgeqrt*. It also exists with a native Fortran interface as *sgeqrt*.

4.19.1312 LAPACKE_sgeqrt2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrt2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, float *a, armpl_int_t lda,
                            float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt2*, *LAPACKE_dgeqrt2*, *LAPACKE_sgeqrt2* and *LAPACKE_zgeqrt2*. It also exists with a native Fortran interface as *sgeqrt2*.

4.19.1313 LAPACKE_sgeqrt2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrt2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, float *a, armpl_int_t lda,
                                 float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt2_work*, *LAPACKE_dgeqrt2_work*, *LAPACKE_sgeqrt2_work* and *LAPACKE_zgeqrt2_work*.

4.19.1314 LAPACKE_sgeqrt3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrt3(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, float *a, armpl_int_t lda,
                            float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt3*, *LAPACKE_dgeqrt3*, *LAPACKE_sgeqrt3* and *LAPACKE_zgeqrt3*. It also exists with a native Fortran interface as *sgeqrt3*.

4.19.1315 LAPACKE_sgeqrt3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrt3_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, float *a, armpl_int_t lda,
                                 float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1316 LAPACKE_sgeqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgeqrt_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nb, float *a,
                                armpl_int_t lda, float *t, armpl_int_t ldt,
                                float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1317 LAPACKE_sgerfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgerfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const float *a,
                           armpl_int_t lda, const float *af, armpl_int_t ldaf,
                           const armpl_int_t *ipiv, const float *b,
                           armpl_int_t ldb, float *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1318 LAPACKE_sgerfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgerfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *a, armpl_int_t lda,
                                const float *af, armpl_int_t ldaf,
                                const armpl_int_t *ipiv, const float *b,
                                armpl_int_t ldb, float *x, armpl_int_t ldx,
                                float *ferr, float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1319 LAPACKE_sgerfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgerfsx(armpl_int_t matrix_layout, char trans, char equed,
                            armpl_int_t n, armpl_int_t nrhs, const float *a,
                            armpl_int_t lda, const float *af,
                            armpl_int_t ldaf, const armpl_int_t *ipiv,
                            const float *r, const float *c, const float *b,
                            armpl_int_t ldb, float *x, armpl_int_t ldx,
                            float *rcond, float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1320 LAPACKE_sgerfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgerfsx_work(armpl_int_t matrix_layout, char trans,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const float *a, armpl_int_t lda,
                                 const float *af, armpl_int_t ldaf,
                                 const armpl_int_t *ipiv, const float *r,
                                 const float *c, const float *b,
                                 armpl_int_t ldb, float *x, armpl_int_t ldx,
                                 float *rcond, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, float *work,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1321 LAPACKE_sgerqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgerqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerqf*, *LAPACKE_dgerqf*, *LAPACKE_sgerqf* and *LAPACKE_zgerqf*. It also exists with a native Fortran interface as *sgerqf*.

4.19.1322 LAPACKE_sgerqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgerqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *tau, float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerqf_work*, *LAPACKE_dgerqf_work*, *LAPACKE_sgerqf_work* and *LAPACKE_zgerqf_work*.

4.19.1323 LAPACKE_sgesdd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesdd(armpl_int_t matrix_layout, char jobz,
                           armpl_int_t m, armpl_int_t n, float *a,
                           armpl_int_t lda, float *s, float *u,
                           armpl_int_t ldu, float *vt, armpl_int_t ldvt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesdd*, *LAPACKE_dgesdd*, *LAPACKE_sgesdd* and *LAPACKE_zgesdd*. It also exists with a native Fortran interface as *sgesdd*.

4.19.1324 LAPACKE_sgesdd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesdd_work(armpl_int_t matrix_layout, char jobz,
                                armpl_int_t m, armpl_int_t n, float *a,
                                armpl_int_t lda, float *s, float *u,
                                armpl_int_t ldu, float *vt, armpl_int_t ldvt,
                                float *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesdd_work*, *LAPACKE_dgesdd_work*, *LAPACKE_sgesdd_work* and *LAPACKE_zgesdd_work*.

4.19.1325 LAPACKE_sgesv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, float *a, armpl_int_t lda,
                          armpl_int_t *ipiv, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesv*, *LAPACKE_dgesv*, *LAPACKE_sgesv* and *LAPACKE_zgesv*. It also exists with a native Fortran interface as *sgesv*.

4.19.1326 LAPACKE_sgesv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, float *a, armpl_int_t lda,
                               armpl_int_t *ipiv, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesv_work*, *LAPACKE_dgesv_work*, *LAPACKE_sgesv_work* and *LAPACKE_zgesv_work*.

4.19.1327 LAPACKE_sgesvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesvd(armpl_int_t matrix_layout, char jobu, char jobvt,
                           armpl_int_t m, armpl_int_t n, float *a,
                           armpl_int_t lda, float *s, float *u,
                           armpl_int_t ldu, float *vt, armpl_int_t ldvt,
                           float *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvd*, *LAPACKE_dgesvd*, *LAPACKE_sgesvd* and *LAPACKE_zgesvd*. It also exists with a native Fortran interface as *sgesvd*.

4.19.1328 LAPACKE_sgesvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesvd_work(armpl_int_t matrix_layout, char jobu,
                                char jobvt, armpl_int_t m, armpl_int_t n,
                                float *a, armpl_int_t lda, float *s, float *u,
                                armpl_int_t ldu, float *vt, armpl_int_t ldvt,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1329 LAPACKE_sgesvdx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesvdx(armpl_int_t matrix_layout, char jobu, char jobvt,
                            char range, armpl_int_t m, armpl_int_t n,
                            float *a, armpl_int_t lda, float vl, float vu,
                            armpl_int_t il, armpl_int_t iu, armpl_int_t *ns,
                            float *s, float *u, armpl_int_t ldu, float *vt,
                            armpl_int_t ldvt, armpl_int_t *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvdx*, *LAPACKE_dgesvdx*, *LAPACKE_sgesvdx* and *LAPACKE_zgesvdx*. It also exists with a native Fortran interface as *sgesvdx*.

4.19.1330 LAPACKE_sgesvdx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesvdx_work(armpl_int_t matrix_layout, char jobu,
                                 char jobvt, char range, armpl_int_t m,
                                 armpl_int_t n, float *a, armpl_int_t lda,
                                 float vl, float vu, armpl_int_t il,
                                 armpl_int_t iu, armpl_int_t *ns, float *s,
                                 float *u, armpl_int_t ldu, float *vt,
                                 armpl_int_t ldvt, float *work,
                                 armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvdx_work*, *LAPACKE_dgesvdx_work*, *LAPACKE_sgesvdx_work* and *LAPACKE_zgesvdx_work*.

4.19.1331 LAPACKE_sgesvj

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesvj(armpl_int_t matrix_layout, char joba, char jobu,
                           char jobv, armpl_int_t m, armpl_int_t n, float *a,
                           armpl_int_t lda, float *sva, armpl_int_t mv,
                           float *v, armpl_int_t ldv, float *stat);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvj*, *LAPACKE_dgesvj*, *LAPACKE_sgesvj* and *LAPACKE_zgesvj*. It also exists with a native Fortran interface as *sgesvj*.

4.19.1332 LAPACKE_sgesvj_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesvj_work(armpl_int_t matrix_layout, char joba,
                                char jobu, char jobv, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *sva, armpl_int_t mv, float *v,
                                armpl_int_t ldv, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvj_work*, *LAPACKE_dgesvj_work*, *LAPACKE_sgesvj_work* and *LAPACKE_zgesvj_work*.

4.19.1333 LAPACKE_sgesvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t nrhs, float *a,
                           armpl_int_t lda, float *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, char *equed, float *r, float *c,
                           float *b, armpl_int_t ldb, float *x,
                           armpl_int_t ldx, float *rcond, float *ferr,
                           float *berr, float *rpivot);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvx*, *LAPACKE_dgesvx*, *LAPACKE_sgesvx* and *LAPACKE_zgesvx*. It also exists with a native Fortran interface as *sgesvx*.

4.19.1334 LAPACKE_sgesvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t nrhs,
                                float *a, armpl_int_t lda, float *af,
                                armpl_int_t ldaf, armpl_int_t *ipiv,
                                char *equed, float *r, float *c, float *b,
                                armpl_int_t ldb, float *x, armpl_int_t ldx,
                                float *rcond, float *ferr, float *berr,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1335 LAPACKE_sgesvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgesvxx(armpl_int_t matrix_layout, char fact, char trans,
                            armpl_int_t n, armpl_int_t nrhs, float *a,
                            armpl_int_t lda, float *af, armpl_int_t ldaf,
                            armpl_int_t *ipiv, char *equed, float *r,
                            float *c, float *b, armpl_int_t ldb, float *x,
                            armpl_int_t ldx, float *rcond, float *rpvgrw,
                            float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1337 LAPACKE_sgetf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetf2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetf2*, *LAPACKE_dgetf2*, *LAPACKE_sgetf2* and *LAPACKE_zgetf2*. It also exists with a native Fortran interface as *sgetf2*.

4.19.1338 LAPACKE_sgetf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetf2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetf2_work*, *LAPACKE_dgetf2_work*, *LAPACKE_sgetf2_work* and *LAPACKE_zgetf2_work*.

4.19.1339 LAPACKE_sgetrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf*, *LAPACKE_dgetrf*, *LAPACKE_sgetrf* and *LAPACKE_zgetrf*. It also exists with a native Fortran interface as *sgetrf*.

4.19.1340 LAPACKE_sgetrf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetrf2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, float *a, armpl_int_t lda,
                            armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf2*, *LAPACKE_dgetrf2*, *LAPACKE_sgetrf2* and *LAPACKE_zgetrf2*. It also exists with a native Fortran interface as *sgetrf2*.

4.19.1341 LAPACKE_sgetrf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetrf2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, float *a, armpl_int_t lda,
                                 armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf2_work*, *LAPACKE_dgetrf2_work*, *LAPACKE_sgetrf2_work* and *LAPACKE_zgetrf2_work*.

4.19.1342 LAPACKE_sgetrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf_work*, *LAPACKE_dgetrf_work*, *LAPACKE_sgetrf_work* and *LAPACKE_zgetrf_work*.

4.19.1343 LAPACKE_sgetri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetri(armpl_int_t matrix_layout, armpl_int_t n, float *a,
                           armpl_int_t lda, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetri*, *LAPACKE_dgetri*, *LAPACKE_sgetri* and *LAPACKE_zgetri*. It also exists with a native Fortran interface as *sgetri*.

4.19.1344 LAPACKE_sgetri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetri_work(armpl_int_t matrix_layout, armpl_int_t n,
                                float *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetri_work*, *LAPACKE_dgetri_work*, *LAPACKE_sgetri_work* and *LAPACKE_zgetri_work*.

4.19.1345 LAPACKE_sgetrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const float *a,
                           armpl_int_t lda, const armpl_int_t *ipiv, float *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrs*, *LAPACKE_dgetrs*, *LAPACKE_sgetrs* and *LAPACKE_zgetrs*. It also exists with a native Fortran interface as *sgetrs*.

4.19.1346 LAPACKE_sgetrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, float *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrs_work*, *LAPACKE_dgetrs_work*, *LAPACKE_sgetrs_work* and *LAPACKE_zgetrs_work*.

4.19.1347 LAPACKE_sgetsls

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetsls(armpl_int_t matrix_layout, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                            float *a, armpl_int_t lda, float *b,
                            armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetsls*, *LAPACKE_dgetsls*, *LAPACKE_sgetsls* and *LAPACKE_zgetsls*. It also exists with a native Fortran interface as *sgetsls*.

4.19.1348 LAPACKE_sgetsls_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgetsls_work(armpl_int_t matrix_layout, char trans,
                                 armpl_int_t m, armpl_int_t n,
                                 armpl_int_t nrhs, float *a, armpl_int_t lda,
                                 float *b, armpl_int_t ldb, float *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetsls_work*, *LAPACKE_dgetsls_work*, *LAPACKE_sgetsls_work* and *LAPACKE_zgetsls_work*.

4.19.1349 LAPACKE_sggbak

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggbak(armpl_int_t matrix_layout, char job, char side,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           const float *lscale, const float *rscale,
                           armpl_int_t m, float *v, armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbak*, *LAPACKE_dggbak*, *LAPACKE_sggbak* and *LAPACKE_zggbak*. It also exists with a native Fortran interface as *sggbak*.

4.19.1350 LAPACKE_sggbak_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggbak_work(armpl_int_t matrix_layout, char job,
                                char side, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, const float *lscale,
                                const float *rscale, armpl_int_t m, float *v,
                                armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbak_work*, *LAPACKE_dggbak_work*, *LAPACKE_sggbak_work* and *LAPACKE_zggbak_work*.

4.19.1351 LAPACKE_sggbal

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggbal(armpl_int_t matrix_layout, char job, armpl_int_t n,
                           float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, armpl_int_t *ilo,
                           armpl_int_t *ihi, float *lscale, float *rscale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbal*, *LAPACKE_dggbal*, *LAPACKE_sggbal* and *LAPACKE_zggbal*. It also exists with a native Fortran interface as *sggbal*.

4.19.1352 LAPACKE_sggbal_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggbal_work(armpl_int_t matrix_layout, char job,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *b, armpl_int_t ldb, armpl_int_t *ilo,
                                armpl_int_t *ihi, float *lscale,
                                float *rscale, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbal_work*, *LAPACKE_dggbal_work*, *LAPACKE_sggbal_work* and *LAPACKE_zggbal_work*.

4.19.1353 LAPACKE_sgges

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgges(armpl_int_t matrix_layout, char jobvsl, char jobvsr,
                          char sort, LAPACK_S_SELECT3 selctg, armpl_int_t n,
                          float *a, armpl_int_t lda, float *b,
                          armpl_int_t ldb, armpl_int_t *sdim, float *alphar,
                          float *alphai, float *beta, float *vsl,
                          armpl_int_t ldvsl, float *vsr, armpl_int_t ldvsr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1354 LAPACKE_sgges3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgges3(armpl_int_t matrix_layout, char jobvsl,
                           char jobvsr, char sort, LAPACK_S_SELECT3 selctg,
                           armpl_int_t n, float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, armpl_int_t *sdim, float *alphar,
                           float *alphai, float *beta, float *vsl,
                           armpl_int_t ldvsl, float *vsr, armpl_int_t ldvsr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgges3*, *LAPACKE_dgges3*, *LAPACKE_sgges3* and *LAPACKE_zgges3*. It also exists with a native Fortran interface as *sgges3*.

4.19.1355 LAPACKE_sgges3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgges3_work(armpl_int_t matrix_layout, char jobvsl,
                                char jobvsr, char sort,
                                LAPACK_S_SELECT3 selctg, armpl_int_t n,
                                float *a, armpl_int_t lda, float *b,
                                armpl_int_t ldb, armpl_int_t *sdim,
                                float *alphar, float *alphai, float *beta,
                                float *vsl, armpl_int_t ldvsl, float *vsr,
                                armpl_int_t ldvsr, float *work,
                                armpl_int_t lwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1357 LAPACKE_sggesx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggesx(armpl_int_t matrix_layout, char jobvsl,
                           char jobvsr, char sort, LAPACK_S_SELECT3 selctg,
                           char sense, armpl_int_t n, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           armpl_int_t *sdim, float *alphar, float *alphai,
                           float *beta, float *vsl, armpl_int_t ldvsl,
```

(continues on next page)

(continued from previous page)

```
                                float *vsr, armpl_int_t ldvsr, float *rconde,
                                float *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggesx*, *LAPACKE_dggesx*, *LAPACKE_sggesx* and *LAPACKE_zggesx*. It also exists with a native Fortran interface as *sggesx*.

4.19.1358 LAPACKE_sggesx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggesx_work(armpl_int_t matrix_layout, char jobvsl,
                                char jobvsr, char sort,
                                LAPACK_S_SELECT3 selctg, char sense,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *b, armpl_int_t ldb, armpl_int_t *sdim,
                                float *alphar, float *alphai, float *beta,
                                float *vsl, armpl_int_t ldvsl, float *vsr,
                                armpl_int_t ldvsr, float *rconde,
                                float *rcondv, float *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork,
                                armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggesx_work*, *LAPACKE_dggesx_work*, *LAPACKE_sggesx_work* and *LAPACKE_zggesx_work*.

4.19.1359 LAPACKE_sggev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggev(armpl_int_t matrix_layout, char jobvl, char jobvr,
                          armpl_int_t n, float *a, armpl_int_t lda, float *b,
                          armpl_int_t ldb, float *alphar, float *alphai,
                          float *beta, float *vl, armpl_int_t ldvl, float *vr,
                          armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev*, *LAPACKE_dggev*, *LAPACKE_sggev* and *LAPACKE_zggev*. It also exists with a native Fortran interface as *sggev*.

4.19.1360 LAPACKE_sggev3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggev3(armpl_int_t matrix_layout, char jobvl, char jobvr,
                           armpl_int_t n, float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, float *alphar, float *alphai,
                           float *beta, float *vl, armpl_int_t ldvl,
                           float *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev3*, *LAPACKE_dggev3*, *LAPACKE_sggev3* and *LAPACKE_zggev3*. It also exists with a native Fortran interface as *sggev3*.

4.19.1361 LAPACKE_sggev3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggev3_work(armpl_int_t matrix_layout, char jobvl,
                                char jobvr, armpl_int_t n, float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                float *alphar, float *alphai, float *beta,
                                float *vl, armpl_int_t ldvl, float *vr,
                                armpl_int_t ldvr, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev3_work*, *LAPACKE_dggev3_work*, *LAPACKE_sggev3_work* and *LAPACKE_zggev3_work*.

4.19.1362 LAPACKE_sggev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggev_work(armpl_int_t matrix_layout, char jobvl,
                               char jobvr, armpl_int_t n, float *a,
                               armpl_int_t lda, float *b, armpl_int_t ldb,
                               float *alphar, float *alphai, float *beta,
                               float *vl, armpl_int_t ldvl, float *vr,
                               armpl_int_t ldvr, float *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev_work*, *LAPACKE_dggev_work*, *LAPACKE_sggev_work* and *LAPACKE_zggev_work*.

4.19.1363 LAPACKE_sggevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggevx(armpl_int_t matrix_layout, char balanc, char jobvl,
                           char jobvr, char sense, armpl_int_t n, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           float *alphar, float *alphai, float *beta,
                           float *vl, armpl_int_t ldvl, float *vr,
                           armpl_int_t ldvr, armpl_int_t *ilo,
                           armpl_int_t *ihi, float *lscale, float *rscale,
                           float *abnrm, float *bbnrm, float *rconde,
                           float *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggevx*, *LAPACKE_dggevx*, *LAPACKE_sggevx* and *LAPACKE_zggevx*. It also exists with a native Fortran interface as *sggevx*.

4.19.1364 LAPACKE_sggevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggevx_work(armpl_int_t matrix_layout, char balanc,
                                char jobvl, char jobvr, char sense,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *b, armpl_int_t ldb, float *alphar,
                                float *alphai, float *beta, float *vl,
                                armpl_int_t ldvl, float *vr, armpl_int_t ldvr,
                                armpl_int_t *ilo, armpl_int_t *ihi,
                                float *lscale, float *rscale, float *abnrm,
                                float *bbnrm, float *rconde, float *rcondv,
                                float *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggevx_work*, *LAPACKE_dggevx_work*, *LAPACKE_sggevx_work* and *LAPACKE_zggevx_work*.

4.19.1365 LAPACKE_sggglm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggglm(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t m, armpl_int_t p, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           float *d, float *x, float *y);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggglm*, *LAPACKE_dggglm*, *LAPACKE_sggglm* and *LAPACKE_zggglm*. It also exists with a native Fortran interface as *sggglm*.

4.19.1366 LAPACKE_sggglm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggglm_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t m, armpl_int_t p, float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                float *d, float *x, float *y, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggglm_work*, *LAPACKE_dggglm_work*, *LAPACKE_sggglm_work* and *LAPACKE_zggglm_work*.

4.19.1367 LAPACKE_sgghd3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgghd3(armpl_int_t matrix_layout, char compq, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, float *q, armpl_int_t ldq,
                           float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghd3*, *LAPACKE_dgghd3*, *LAPACKE_sgghd3* and *LAPACKE_zgghd3*. It also exists with a native Fortran interface as *sgghd3*.

4.19.1368 LAPACKE_sgghd3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgghd3_work(armpl_int_t matrix_layout, char compq,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, float *a, armpl_int_t lda,

```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldq, float *z, armpl_int_t ldz,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1369 LAPACKE_sgghrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgghrd(armpl_int_t matrix_layout, char compq, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, float *q, armpl_int_t ldq,
                           float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghrd*, *LAPACKE_dgghrd*, *LAPACKE_sgghrd* and *LAPACKE_zgghrd*. It also exists with a native Fortran interface as *sgghrd*.

4.19.1370 LAPACKE_sgghrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgghrd_work(armpl_int_t matrix_layout, char compq,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, float *a, armpl_int_t lda,
                                float *b, armpl_int_t ldb, float *q,
                                armpl_int_t ldq, float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghrd_work*, *LAPACKE_dgghrd_work*, *LAPACKE_sgghrd_work* and *LAPACKE_zgghrd_work*.

4.19.1371 LAPACKE_sgglse

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgglse(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t p, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           float *c, float *d, float *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgglse*, *LAPACKE_dgglse*, *LAPACKE_sgglse* and *LAPACKE_zgglse*. It also exists with a native Fortran interface as *sgglse*.

4.19.1372 LAPACKE_sgglse_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgglse_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t p, float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                float *c, float *d, float *x, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgglse_work*, *LAPACKE_dgglse_work*, *LAPACKE_sgglse_work* and *LAPACKE_zgglse_work*.

4.19.1373 LAPACKE_sggqrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggqrf(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t m, armpl_int_t p, float *a,
                           armpl_int_t lda, float *taua, float *b,
                           armpl_int_t ldb, float *taub);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggqrf*, *LAPACKE_dggqrf*, *LAPACKE_sggqrf* and *LAPACKE_zggqrf*. It also exists with a native Fortran interface as *sggqrf*.

4.19.1374 LAPACKE_sggqrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggqrf_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t m, armpl_int_t p, float *a,
                                armpl_int_t lda, float *taua, float *b,
                                armpl_int_t ldb, float *taub, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggqrf_work*, *LAPACKE_dggqrf_work*, *LAPACKE_sggqrf_work* and *LAPACKE_zggqrf_work*.

4.19.1375 LAPACKE_sggrqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggrqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t p, armpl_int_t n, float *a,
                           armpl_int_t lda, float *taua, float *b,
                           armpl_int_t ldb, float *taub);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggrqf*, *LAPACKE_dggrqf*, *LAPACKE_sggrqf* and *LAPACKE_zggrqf*. It also exists with a native Fortran interface as *sggrqf*.

4.19.1376 LAPACKE_sggrqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggrqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n, float *a,
                                armpl_int_t lda, float *taua, float *b,
                                armpl_int_t ldb, float *taub, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggrqf_work*, *LAPACKE_dggrqf_work*, *LAPACKE_sggrqf_work* and *LAPACKE_zggrqf_work*.

4.19.1377 LAPACKE_sggsvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggsvd(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t n,
                           armpl_int_t p, armpl_int_t *k, armpl_int_t *l,
                           float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, float *alpha, float *beta,
                           float *u, armpl_int_t ldu, float *v,
                           armpl_int_t ldv, float *q, armpl_int_t ldq,
                           armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd*, *LAPACKE_dggsvd*, *LAPACKE_sggsvd* and *LAPACKE_zggsvd*.

4.19.1378 LAPACKE_sggsvd3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggsvd3(armpl_int_t matrix_layout, char jobu, char jobv,
                            char jobq, armpl_int_t m, armpl_int_t n,
                            armpl_int_t p, armpl_int_t *k, armpl_int_t *l,
                            float *a, armpl_int_t lda, float *b,
                            armpl_int_t ldb, float *alpha, float *beta,
                            float *u, armpl_int_t ldu, float *v,
                            armpl_int_t ldv, float *q, armpl_int_t ldq,
                            armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd3*, *LAPACKE_dggsvd3*, *LAPACKE_sggsvd3* and *LAPACKE_zggsvd3*. It also exists with a native Fortran interface as *sggsvd3*.

4.19.1379 LAPACKE_sggsvd3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggsvd3_work(armpl_int_t matrix_layout, char jobu,
                                 char jobv, char jobq, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t p, armpl_int_t *k,
                                 armpl_int_t *l, float *a, armpl_int_t lda,
                                 float *b, armpl_int_t ldb, float *alpha,
                                 float *beta, float *u, armpl_int_t ldu,
                                 float *v, armpl_int_t ldv, float *q,
                                 armpl_int_t ldq, float *work,
                                 armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd3_work*, *LAPACKE_dggsvd3_work*, *LAPACKE_sggsvd3_work* and *LAPACKE_zggsvd3_work*.

4.19.1380 LAPACKE_sggsvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggsvd_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t n, armpl_int_t p, armpl_int_t *k,
                                armpl_int_t *l, float *a, armpl_int_t lda,
                                float *b, armpl_int_t ldb, float *alpha,
                                float *beta, float *u, armpl_int_t ldu,
                                float *v, armpl_int_t ldv, float *q,
                                armpl_int_t ldq, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd_work*, *LAPACKE_dggsvd_work*, *LAPACKE_sggsvd_work* and *LAPACKE_zggsvd_work*.

4.19.1381 LAPACKE_sggsvp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggsvp(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t p,
                           armpl_int_t n, float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, float tola, float tolb,
                           armpl_int_t *k, armpl_int_t *l, float *u,
                           armpl_int_t ldu, float *v, armpl_int_t ldv,
                           float *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp*, *LAPACKE_dggsvp*, *LAPACKE_sggsvp* and *LAPACKE_zggsvp*.

4.19.1382 LAPACKE_sggsvp3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggsvp3(armpl_int_t matrix_layout, char jobu, char jobv,
                            char jobq, armpl_int_t m, armpl_int_t p,
                            armpl_int_t n, float *a, armpl_int_t lda,
                            float *b, armpl_int_t ldb, float tola, float tolb,
                            armpl_int_t *k, armpl_int_t *l, float *u,
                            armpl_int_t ldu, float *v, armpl_int_t ldv,
                            float *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp3*, *LAPACKE_dggsvp3*, *LAPACKE_sggsvp3* and *LAPACKE_zggsvp3*. It also exists with a native Fortran interface as *sggsvp3*.

4.19.1383 LAPACKE_sggsvp3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggsvp3_work(armpl_int_t matrix_layout, char jobu,
                                 char jobv, char jobq, armpl_int_t m,
                                 armpl_int_t p, armpl_int_t n, float *a,
                                 armpl_int_t lda, float *b, armpl_int_t ldb,
                                 float tola, float tolb, armpl_int_t *k,
                                 armpl_int_t *l, float *u, armpl_int_t ldu,
                                 float *v, armpl_int_t ldv, float *q,
                                 armpl_int_t ldq, armpl_int_t *iwork,
                                 float *tau, float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1384 LAPACKE_sggsvp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sggsvp_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n, float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                float tola, float tolb, armpl_int_t *k,
                                armpl_int_t *l, float *u, armpl_int_t ldu,
                                float *v, armpl_int_t ldv, float *q,
                                armpl_int_t ldq, armpl_int_t *iwork,
                                float *tau, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1385 LAPACKE_sgtcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgtcon(char norm, armpl_int_t n, const float *dl,
                           const float *d, const float *du, const float *du2,
                           const armpl_int_t *ipiv, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtcon*, *LAPACKE_dgtcon*, *LAPACKE_sgtcon* and *LAPACKE_zgtcon*. It also exists with a native Fortran interface as *sgtcon*.

4.19.1386 LAPACKE_sgtcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgtcon_work(char norm, armpl_int_t n, const float *dl,
                                const float *d, const float *du,
                                const float *du2, const armpl_int_t *ipiv,
                                float anorm, float *rcond, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1387 LAPACKE_sgtrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgtrfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const float *dl,
                           const float *d, const float *du, const float *dlf,
                           const float *df, const float *duf,
                           const float *du2, const armpl_int_t *ipiv,
                           const float *b, armpl_int_t ldb, float *x,
                           armpl_int_t ldx, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtrfs*, *LAPACKE_dgtrfs*, *LAPACKE_sgtrfs* and *LAPACKE_zgtrfs*. It also exists with a native Fortran interface as *sgtrfs*.

4.19.1388 LAPACKE_sgtrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgtrfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *dl, const float *d,
                                const float *du, const float *dlf,
                                const float *df, const float *duf,
                                const float *du2, const armpl_int_t *ipiv,
                                const float *b, armpl_int_t ldb, float *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtrfs_work*, *LAPACKE_dgtrfs_work*, *LAPACKE_sgtrfs_work* and *LAPACKE_zgtrfs_work*.

4.19.1389 LAPACKE_sgtsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgtsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, float *dl, float *d, float *du,
                          float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsv*, *LAPACKE_dgtsv*, *LAPACKE_sgtsv* and *LAPACKE_zgtsv*. It also exists with a native Fortran interface as *sgtsv*.

4.19.1390 LAPACKE_sgtsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgtsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, float *dl, float *d,
                               float *du, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1391 LAPACKE_sgtsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgtsvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const float *dl,
                           const float *d, const float *du, float *dlf,
                           float *df, float *duf, float *du2,
                           armpl_int_t *ipiv, const float *b, armpl_int_t ldb,
                           float *x, armpl_int_t ldx, float *rcond,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsvx*, *LAPACKE_dgtsvx*, *LAPACKE_sgtsvx* and *LAPACKE_zgtsvx*. It also exists with a native Fortran interface as *sgtsvx*.

4.19.1392 LAPACKE_sgtsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgtsvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t nrhs,
```

(continues on next page)

(continued from previous page)

```
                                const float *dl, const float *d,
                                const float *du, float *dlf, float *df,
                                float *duf, float *du2, armpl_int_t *ipiv,
                                const float *b, armpl_int_t ldb, float *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsvx_work*, *LAPACKE_dgtsvx_work*, *LAPACKE_sgtsvx_work* and *LAPACKE_zgtsvx_work*.

4.19.1393 LAPACKE_sgttrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgttrf(armpl_int_t n, float *dl, float *d, float *du,
                           float *du2, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrf*, *LAPACKE_dgttrf*, *LAPACKE_sgttrf* and *LAPACKE_zgttrf*. It also exists with a native Fortran interface as *sgttrf*.

4.19.1394 LAPACKE_sgttrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgttrf_work(armpl_int_t n, float *dl, float *d, float *du,
                                float *du2, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrf_work*, *LAPACKE_dgttrf_work*, *LAPACKE_sgttrf_work* and *LAPACKE_zgttrf_work*.

4.19.1395 LAPACKE_sgttrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgttrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs, const float *dl,
                           const float *d, const float *du, const float *du2,
                           const armpl_int_t *ipiv, float *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrs*, *LAPACKE_dgttrs*, *LAPACKE_sgttrs* and *LAPACKE_zgttrs*. It also exists with a native Fortran interface as *sgttrs*.

4.19.1396 LAPACKE_sgttrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sgttrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *dl, const float *d,
                                const float *du, const float *du2,
                                const armpl_int_t *ipiv, float *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1397 LAPACKE_shgeqz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_shgeqz(armpl_int_t matrix_layout, char job, char compq,
                           char compz, armpl_int_t n, armpl_int_t ilo,
                           armpl_int_t ihi, float *h, armpl_int_t ldh,
                           float *t, armpl_int_t ldt, float *alphar,
                           float *alphai, float *beta, float *q,
                           armpl_int_t ldq, float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chgeqz*, *LAPACKE_dhgeqz*, *LAPACKE_shgeqz* and *LAPACKE_zhgeqz*. It also exists with a native Fortran interface as *shgeqz*.

4.19.1398 LAPACKE_shgeqz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_shgeqz_work(armpl_int_t matrix_layout, char job,
                                char compq, char compz, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi, float *h,
                                armpl_int_t ldh, float *t, armpl_int_t ldt,
                                float *alphar, float *alphai, float *beta,
                                float *q, armpl_int_t ldq, float *z,
                                armpl_int_t ldz, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chgeqz_work*, *LAPACKE_dhgeqz_work*, *LAPACKE_shgeqz_work* and *LAPACKE_zhgeqz_work*.

4.19.1399 LAPACKE_shsein

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_shsein(armpl_int_t matrix_layout, char job, char eigsrc,
                           char initv, armpl_int_t *select, armpl_int_t n,
                           const float *h, armpl_int_t ldh, float *wr,
                           const float *wi, float *vl, armpl_int_t ldvl,
                           float *vr, armpl_int_t ldvr, armpl_int_t mm,
                           armpl_int_t *m, armpl_int_t *ifaill,
                           armpl_int_t *ifailr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chsein*, *LAPACKE_dhsein*, *LAPACKE_shsein* and *LAPACKE_zhsein*. It also exists with a native Fortran interface as *shsein*.

4.19.1400 LAPACKE_shsein_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_shsein_work(armpl_int_t matrix_layout, char job,
                                char eigsrc, char initv, armpl_int_t *select,
                                armpl_int_t n, const float *h,
                                armpl_int_t ldh, float *wr, const float *wi,
                                float *vl, armpl_int_t ldvl, float *vr,
                                armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, float *work,
                                armpl_int_t *ifaill, armpl_int_t *ifailr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chsein_work*, *LAPACKE_dhsein_work*, *LAPACKE_shsein_work* and *LAPACKE_zhsein_work*.

4.19.1401 LAPACKE_shseqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_shseqr(armpl_int_t matrix_layout, char job, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           float *h, armpl_int_t ldh, float *wr, float *wi,
                           float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chseqr*, *LAPACKE_dhseqr*, *LAPACKE_shseqr* and *LAPACKE_zhseqr*. It also exists with a native Fortran interface as *shseqr*.

4.19.1402 LAPACKE_shseqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_shseqr_work(armpl_int_t matrix_layout, char job,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, float *h, armpl_int_t ldh,
                                float *wr, float *wi, float *z,
                                armpl_int_t ldz, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1403 LAPACKE_slacn2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slacn2(armpl_int_t n, float *v, float *x,
                           armpl_int_t *isgn, float *est, armpl_int_t *kase,
                           armpl_int_t *isave);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacn2*, *LAPACKE_dlacn2*, *LAPACKE_slacn2* and *LAPACKE_zlacn2*. It also exists with a native Fortran interface as *slacn2*.

4.19.1404 LAPACKE_slacn2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slacn2_work(armpl_int_t n, float *v, float *x,
                                armpl_int_t *isgn, float *est,
                                armpl_int_t *kase, armpl_int_t *isave);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacn2_work*, *LAPACKE_dlacn2_work*, *LAPACKE_slacn2_work* and *LAPACKE_zlacn2_work*.

4.19.1405 LAPACKE_slacpy

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slacpy(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n, const float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacpy*, *LAPACKE_dlacpy*, *LAPACKE_slacpy* and *LAPACKE_zlacpy*. It also exists with a native Fortran interface as *slacpy*.

4.19.1406 LAPACKE_slacpy_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slacpy_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n, const float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacpy_work*, *LAPACKE_dlacpy_work*, *LAPACKE_slacpy_work* and *LAPACKE_zlacpy_work*.

4.19.1407 LAPACKE_slag2d

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slag2d(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const float *sa, armpl_int_t ldsa,
                           double *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_slag2d*. It also exists with a native Fortran interface as *slag2d*.

4.19.1408 LAPACKE_slag2d_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slag2d_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const float *sa,
                                armpl_int_t ldsa, double *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_slag2d_work*.

4.19.1409 LAPACKE_slagge

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.1410 LAPACKE_slagge_work

Syntax

4.19.1411 LAPACKE_slagsy

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.1412 LAPACKE_slagsy_work

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.1413 LAPACKE_slamch

Syntax

```
#include "armpl.h"

float LAPACKE_slamch(char cmach);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlamch* and *LAPACKE_slamch*.

4.19.1414 LAPACKE_slamch_work

Syntax

```
#include "armpl.h"

float LAPACKE_slamch_work(char cmach);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlamch_work* and *LAPACKE_slamch_work*.

4.19.1415 LAPACKE_slange

Syntax

```
#include "armpl.h"

float LAPACKE_slange(armpl_int_t matrix_layout, char norm, armpl_int_t m,
                     armpl_int_t n, const float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clange*, *LAPACKE_dlange*, *LAPACKE_slange* and *LAPACKE_zlange*. It also exists with a native Fortran interface as *slange*.

4.19.1416 LAPACKE_slange_work

Syntax

```
#include "armpl.h"

float LAPACKE_slange_work(armpl_int_t matrix_layout, char norm, armpl_int_t m,
                          armpl_int_t n, const float *a, armpl_int_t lda,
                          float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clange_work*, *LAPACKE_dlange_work*, *LAPACKE_slange_work* and *LAPACKE_zlange_work*.

4.19.1417 LAPACKE_slansy

Syntax

```
#include "armpl.h"

float LAPACKE_slansy(armpl_int_t matrix_layout, char norm, char uplo,
                     armpl_int_t n, const float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clansy*, *LAPACKE_dlansy*, *LAPACKE_slansy* and *LAPACKE_zlansy*. It also exists with a native Fortran interface as *slansy*.

4.19.1418 LAPACKE_slansy_work

Syntax

```
#include "armpl.h"

float LAPACKE_slansy_work(armpl_int_t matrix_layout, char norm, char uplo,
                          armpl_int_t n, const float *a, armpl_int_t lda,
                          float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clansy_work*, *LAPACKE_dlansy_work*, *LAPACKE_slansy_work* and *LAPACKE_zlansy_work*.

4.19.1419 LAPACKE_slantr

Syntax

```
#include "armpl.h"

float LAPACKE_slantr(armpl_int_t matrix_layout, char norm, char uplo,
                     char diag, armpl_int_t m, armpl_int_t n, const float *a,
                     armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clantr*, *LAPACKE_dlantr*, *LAPACKE_slantr* and *LAPACKE_zlantr*. It also exists with a native Fortran interface as *slantr*.

4.19.1420 LAPACKE_slantr_work

Syntax

```
#include "armpl.h"

float LAPACKE_slantr_work(armpl_int_t matrix_layout, char norm, char uplo,
                          char diag, armpl_int_t m, armpl_int_t n,
                          const float *a, armpl_int_t lda, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clantr_work*, *LAPACKE_dlantr_work*, *LAPACKE_slantr_work* and *LAPACKE_zlantr_work*.

4.19.1421 LAPACKE_slapmr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slapmr(armpl_int_t matrix_layout, armpl_int_t forwrd,
                           armpl_int_t m, armpl_int_t n, float *x,
                           armpl_int_t ldx, armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmr*, *LAPACKE_dlapmr*, *LAPACKE_slapmr* and *LAPACKE_zlapmr*. It also exists with a native Fortran interface as *slapmr*.

4.19.1422 LAPACKE_slapmr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slapmr_work(armpl_int_t matrix_layout, armpl_int_t forwrd,
                                armpl_int_t m, armpl_int_t n, float *x,
                                armpl_int_t ldx, armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmr_work*, *LAPACKE_dlapmr_work*, *LAPACKE_slapmr_work* and *LAPACKE_zlapmr_work*.

4.19.1423 LAPACKE_slapmt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slapmt(armpl_int_t matrix_layout, armpl_int_t forwrd,
                           armpl_int_t m, armpl_int_t n, float *x,
                           armpl_int_t ldx, armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmt*, *LAPACKE_dlapmt*, *LAPACKE_slapmt* and *LAPACKE_zlapmt*. It also exists with a native Fortran interface as *slapmt*.

4.19.1424 LAPACKE_slapmt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slapmt_work(armpl_int_t matrix_layout, armpl_int_t forwrd,
                                armpl_int_t m, armpl_int_t n, float *x,
                                armpl_int_t ldx, armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1425 LAPACKE_slapy2

Syntax

```
#include "armpl.h"

float LAPACKE_slapy2(float x, float y);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlapy2* and *LAPACKE_slapy2*. It also exists with a native Fortran interface as *slapy2*.

4.19.1426 LAPACKE_slapy2_work

Syntax

```
#include "armpl.h"

float LAPACKE_slapy2_work(float x, float y);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlapy2_work* and *LAPACKE_slapy2_work*.

4.19.1427 LAPACKE_slapy3

Syntax

```
#include "armpl.h"

float LAPACKE_slapy3(float x, float y, float z);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlapy3* and *LAPACKE_slapy3*. It also exists with a native Fortran interface as *slapy3*.

4.19.1428 LAPACKE_slapy3_work

Syntax

```
#include "armpl.h"

float LAPACKE_slapy3_work(float x, float y, float z);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlapy3_work* and *LAPACKE_slapy3_work*.

4.19.1429 LAPACKE_slarfb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarfb(armpl_int_t matrix_layout, char side, char trans,
                           char direct, char storev, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, const float *v,
                           armpl_int_t ldv, const float *t, armpl_int_t ldt,
                           float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfb*, *LAPACKE_dlarfb*, *LAPACKE_slarfb* and *LAPACKE_zlarfb*. It also exists with a native Fortran interface as *slarfb*.

4.19.1430 LAPACKE_slarfb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarfb_work(armpl_int_t matrix_layout, char side,
                                char trans, char direct, char storev,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                const float *v, armpl_int_t ldv,
                                const float *t, armpl_int_t ldt, float *c,
                                armpl_int_t ldc, float *work,
                                armpl_int_t ldwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfb_work*, *LAPACKE_dlarfb_work*, *LAPACKE_slarfb_work* and *LAPACKE_zlarfb_work*.

4.19.1431 LAPACKE_slarfg

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarfg(armpl_int_t n, float *alpha, float *x,
                           armpl_int_t incx, float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfg*, *LAPACKE_dlarfg*, *LAPACKE_slarfg* and *LAPACKE_zlarfg*. It also exists with a native Fortran interface as *slarfg*.

4.19.1432 LAPACKE_slarfg_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarfg_work(armpl_int_t n, float *alpha, float *x,
                                armpl_int_t incx, float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfg_work*, *LAPACKE_dlarfg_work*, *LAPACKE_slarfg_work* and *LAPACKE_zlarfg_work*.

4.19.1433 LAPACKE_slarft

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarft(armpl_int_t matrix_layout, char direct,
                           char storev, armpl_int_t n, armpl_int_t k,
                           const float *v, armpl_int_t ldv, const float *tau,
                           float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarft*, *LAPACKE_dlarft*, *LAPACKE_slarft* and *LAPACKE_zlarft*. It also exists with a native Fortran interface as *slarft*.

4.19.1434 LAPACKE_slarft_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarft_work(armpl_int_t matrix_layout, char direct,
                                char storev, armpl_int_t n, armpl_int_t k,
                                const float *v, armpl_int_t ldv,
                                const float *tau, float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarft_work*, *LAPACKE_dlarft_work*, *LAPACKE_slarft_work* and *LAPACKE_zlarft_work*.

4.19.1435 LAPACKE_slarfx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarfx(armpl_int_t matrix_layout, char side,
                           armpl_int_t m, armpl_int_t n, const float *v,
                           float tau, float *c, armpl_int_t ldc,
                           float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfx*, *LAPACKE_dlarfx*, *LAPACKE_slarfx* and *LAPACKE_zlarfx*. It also exists with a native Fortran interface as *slarfx*.

4.19.1436 LAPACKE_slarfx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarfx_work(armpl_int_t matrix_layout, char side,
                                armpl_int_t m, armpl_int_t n, const float *v,
                                float tau, float *c, armpl_int_t ldc,
                                float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfx_work*, *LAPACKE_dlarfx_work*, *LAPACKE_slarfx_work* and *LAPACKE_zlarfx_work*.

4.19.1437 LAPACKE_slarnv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarnv(armpl_int_t idist, armpl_int_t *iseed,
                           armpl_int_t n, float *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarnv*, *LAPACKE_dlarnv*, *LAPACKE_slarnv* and *LAPACKE_zlarnv*. It also exists with a native Fortran interface as *slarnv*.

4.19.1438 LAPACKE_slarnv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slarnv_work(armpl_int_t idist, armpl_int_t *iseed,
                                armpl_int_t n, float *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarnv_work*, *LAPACKE_dlarnv_work*, *LAPACKE_slarnv_work* and *LAPACKE_zlarnv_work*.

4.19.1439 LAPACKE_slartgp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slartgp(float f, float g, float *cs, float *sn,
                            float *r);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlartgp* and *LAPACKE_slartgp*. It also exists with a native Fortran interface as *slartgp*.

4.19.1440 LAPACKE_slartgp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slartgp_work(float f, float g, float *cs, float *sn,
                                 float *r);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlartgp_work* and *LAPACKE_slartgp_work*.

4.19.1441 LAPACKE_slartgs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slartgs(float x, float y, float sigma, float *cs,
                            float *sn);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlartgs* and *LAPACKE_slartgs*. It also exists with a native Fortran interface as *slartgs*.

4.19.1442 LAPACKE_slartgs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slartgs_work(float x, float y, float sigma, float *cs,
                                 float *sn);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlartgs_work* and *LAPACKE_slartgs_work*.

4.19.1443 LAPACKE_slascl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slascl(armpl_int_t matrix_layout, char type,
                           armpl_int_t kl, armpl_int_t ku, float cfrom,
                           float cto, armpl_int_t m, armpl_int_t n, float *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1444 LAPACKE_slascl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slascl_work(armpl_int_t matrix_layout, char type,
                                armpl_int_t kl, armpl_int_t ku, float cfrom,
                                float cto, armpl_int_t m, armpl_int_t n,
                                float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clascl_work*, *LAPACKE_dlascl_work*, *LAPACKE_slascl_work* and *LAPACKE_zlascl_work*.

4.19.1445 LAPACKE_slaset

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slaset(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n, float alpha,
                           float beta, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claset*, *LAPACKE_dlaset*, *LAPACKE_slaset* and *LAPACKE_zlaset*. It also exists with a native Fortran interface as *slaset*.

4.19.1446 LAPACKE_slaset_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slaset_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n, float alpha,
                                float beta, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claset_work*, *LAPACKE_dlaset_work*, *LAPACKE_slaset_work* and *LAPACKE_zlaset_work*.

4.19.1447 LAPACKE_slasrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slasrt(char id, armpl_int_t n, float *d);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlasrt* and *LAPACKE_slasrt*. It also exists with a native Fortran interface as *slasrt*.

4.19.1448 LAPACKE_slasrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slasrt_work(char id, armpl_int_t n, float *d);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dlasrt_work* and *LAPACKE_slasrt_work*.

4.19.1449 LAPACKE_slassq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slassq(armpl_int_t n, float *x, armpl_int_t incx,
                           float *scale, float *sumsq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_classq*, *LAPACKE_dlassq*, *LAPACKE_slassq* and *LAPACKE_zlassq*. It also exists with a native Fortran interface as *slassq*.

4.19.1450 LAPACKE_slassq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slassq_work(armpl_int_t n, float *x, armpl_int_t incx,
                                float *scale, float *sumsq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_classq_work*, *LAPACKE_dlassq_work*, *LAPACKE_slassq_work* and *LAPACKE_zlassq_work*.

4.19.1451 LAPACKE_slaswp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slaswp(armpl_int_t matrix_layout, armpl_int_t n, float *a,
                           armpl_int_t lda, armpl_int_t k1, armpl_int_t k2,
                           const armpl_int_t *ipiv, armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claswp*, *LAPACKE_dlaswp*, *LAPACKE_slaswp* and *LAPACKE_zlaswp*. It also exists with a native Fortran interface as *slaswp*.

4.19.1452 LAPACKE_slaswp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slaswp_work(armpl_int_t matrix_layout, armpl_int_t n,
                                float *a, armpl_int_t lda, armpl_int_t k1,
                                armpl_int_t k2, const armpl_int_t *ipiv,
                                armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claswp_work*, *LAPACKE_dlaswp_work*, *LAPACKE_slaswp_work* and *LAPACKE_zlaswp_work*.

4.19.1453 LAPACKE_slatms

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.1454 LAPACKE_slatms_work

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.1455 LAPACKE_slauum

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slauum(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clauum*, *LAPACKE_dlauum*, *LAPACKE_slauum* and *LAPACKE_zlauum*. It also exists with a native Fortran interface as *slauum*.

4.19.1456 LAPACKE_slauum_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_slauum_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clauum_work*, *LAPACKE_dlauum_work*, *LAPACKE_slauum_work* and *LAPACKE_zlauum_work*.

4.19.1457 LAPACKE_sopgtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sopgtr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const float *ap, const float *tau,
                           float *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dopgtr* and *LAPACKE_sopgtr*. It also exists with a native Fortran interface as *sopgtr*.

4.19.1458 LAPACKE_sopgtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sopgtr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const float *ap,
                                const float *tau, float *q, armpl_int_t ldq,
                                float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dopgtr_work* and *LAPACKE_sopgtr_work*.

4.19.1459 LAPACKE_sopmtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sopmtr(armpl_int_t matrix_layout, char side, char uplo,
                           char trans, armpl_int_t m, armpl_int_t n,
                           const float *ap, const float *tau, float *c,
                           armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dopmtr* and *LAPACKE_sopmtr*. It also exists with a native Fortran interface as *sopmtr*.

4.19.1460 LAPACKE_sopmtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sopmtr_work(armpl_int_t matrix_layout, char side,
                                char uplo, char trans, armpl_int_t m,
                                armpl_int_t n, const float *ap,
                                const float *tau, float *c, armpl_int_t ldc,
                                float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dopmtr_work* and *LAPACKE_sopmtr_work*.

4.19.1461 LAPACKE_sorbdb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorbdb(armpl_int_t matrix_layout, char trans, char signs,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           float *x11, armpl_int_t ldx11, float *x12,
                           armpl_int_t ldx12, float *x21, armpl_int_t ldx21,
                           float *x22, armpl_int_t ldx22, float *theta,
                           float *phi, float *taup1, float *taup2,
                           float *tauq1, float *tauq2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorbdb* and *LAPACKE_sorbdb*. It also exists with a native Fortran interface as *sorbdb*.

4.19.1462 LAPACKE_sorbdb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorbdb_work(armpl_int_t matrix_layout, char trans,
                                char signs, armpl_int_t m, armpl_int_t p,
                                armpl_int_t q, float *x11, armpl_int_t ldx11,
                                float *x12, armpl_int_t ldx12, float *x21,
                                armpl_int_t ldx21, float *x22,
                                armpl_int_t ldx22, float *theta, float *phi,
                                float *taup1, float *taup2, float *tauq1,
                                float *tauq2, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorbdb_work* and *LAPACKE_sorbdb_work*.

4.19.1463 LAPACKE_sorcsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorcsd(armpl_int_t matrix_layout, char jobu1, char jobu2,
                           char jobv1t, char jobv2t, char trans, char signs,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           float *x11, armpl_int_t ldx11, float *x12,
                           armpl_int_t ldx12, float *x21, armpl_int_t ldx21,
                           float *x22, armpl_int_t ldx22, float *theta,
                           float *u1, armpl_int_t ldu1, float *u2,
                           armpl_int_t ldu2, float *v1t, armpl_int_t ldv1t,
                           float *v2t, armpl_int_t ldv2t);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorcsd_work* and *LAPACKE_sorcsd_work*.

4.19.1467 LAPACKE_sorgbr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgbr(armpl_int_t matrix_layout, char vect,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           float *a, armpl_int_t lda, const float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgbr* and *LAPACKE_sorgbr*. It also exists with a native Fortran interface as *sorgbr*.

4.19.1468 LAPACKE_sorgbr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgbr_work(armpl_int_t matrix_layout, char vect,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                float *a, armpl_int_t lda, const float *tau,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgbr_work* and *LAPACKE_sorgbr_work*.

4.19.1469 LAPACKE_sorghr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorghr(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t ilo, armpl_int_t ihi, float *a,
                           armpl_int_t lda, const float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorghr* and *LAPACKE_sorghr*. It also exists with a native Fortran interface as *sorghr*.

4.19.1470 LAPACKE_sorghr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorghr_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi, float *a,
                                armpl_int_t lda, const float *tau,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorghr_work* and *LAPACKE_sorghr_work*.

4.19.1471 LAPACKE_sorglq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorglq(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, float *a,
                           armpl_int_t lda, const float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorglq* and *LAPACKE_sorglq*. It also exists with a native Fortran interface as *sorglq*.

4.19.1472 LAPACKE_sorglq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorglq_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, float *a,
                                armpl_int_t lda, const float *tau,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorglq_work* and *LAPACKE_sorglq_work*.

4.19.1473 LAPACKE_sorgql

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgql(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, float *a,
                           armpl_int_t lda, const float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgql* and *LAPACKE_sorgql*. It also exists with a native Fortran interface as *sorgql*.

4.19.1474 LAPACKE_sorgql_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgql_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, float *a,
                                armpl_int_t lda, const float *tau,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgql_work* and *LAPACKE_sorgql_work*.

4.19.1475 LAPACKE_sorgqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgqr(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, float *a,
                           armpl_int_t lda, const float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgqr* and *LAPACKE_sorgqr*. It also exists with a native Fortran interface as *sorgqr*.

4.19.1476 LAPACKE_sorgqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgqr_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, float *a,
                                armpl_int_t lda, const float *tau,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgqr_work* and *LAPACKE_sorgqr_work*.

4.19.1477 LAPACKE_sorgrq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgrq(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, float *a,
                           armpl_int_t lda, const float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgrq* and *LAPACKE_sorgrq*. It also exists with a native Fortran interface as *sorgrq*.

4.19.1478 LAPACKE_sorgrq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgrq_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, float *a,
                                armpl_int_t lda, const float *tau,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgrq_work* and *LAPACKE_sorgrq_work*.

4.19.1479 LAPACKE_sorgtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgtr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           const float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgtr* and *LAPACKE_sorgtr*. It also exists with a native Fortran interface as *sorgtr*.

4.19.1480 LAPACKE_sorgtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sorgtr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                const float *tau, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dorgtr_work* and *LAPACKE_sorgtr_work*.

4.19.1481 LAPACKE_sormbr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormbr(armpl_int_t matrix_layout, char vect, char side,
                           char trans, armpl_int_t m, armpl_int_t n,
                           armpl_int_t k, const float *a, armpl_int_t lda,
                           const float *tau, float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormbr* and *LAPACKE_sormbr*. It also exists with a native Fortran interface as *sormbr*.

4.19.1482 LAPACKE_sormbr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormbr_work(armpl_int_t matrix_layout, char vect,
                                char side, char trans, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k, const float *a,
                                armpl_int_t lda, const float *tau, float *c,
                                armpl_int_t ldc, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormbr_work* and *LAPACKE_sormbr_work*.

4.19.1483 LAPACKE_sormhr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormhr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t ilo,
                           armpl_int_t ihi, const float *a, armpl_int_t lda,
                           const float *tau, float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormhr* and *LAPACKE_sormhr*. It also exists with a native Fortran interface as *sormhr*.

4.19.1484 LAPACKE_sormhr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormhr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi,
                                const float *a, armpl_int_t lda,
                                const float *tau, float *c, armpl_int_t ldc,
                                float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormhr_work* and *LAPACKE_sormhr_work*.

4.19.1485 LAPACKE_sormlq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormlq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const float *a, armpl_int_t lda, const float *tau,
                           float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormlq* and *LAPACKE_sormlq*. It also exists with a native Fortran interface as *sormlq*.

4.19.1486 LAPACKE_sormlq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormlq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const float *a,
                                armpl_int_t lda, const float *tau, float *c,
                                armpl_int_t ldc, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormlq_work* and *LAPACKE_sormlq_work*.

4.19.1487 LAPACKE_sormql

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormql(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const float *a, armpl_int_t lda, const float *tau,
                           float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormql* and *LAPACKE_sormql*. It also exists with a native Fortran interface as *sormql*.

4.19.1488 LAPACKE_sormql_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormql_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const float *a,
                                armpl_int_t lda, const float *tau, float *c,
                                armpl_int_t ldc, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormql_work* and *LAPACKE_sormql_work*.

4.19.1489 LAPACKE_sormqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormqr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const float *a, armpl_int_t lda, const float *tau,
                           float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormqr* and *LAPACKE_sormqr*. It also exists with a native Fortran interface as *sormqr*.

4.19.1490 LAPACKE_sormqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormqr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const float *a,
                                armpl_int_t lda, const float *tau, float *c,
                                armpl_int_t ldc, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormqr_work* and *LAPACKE_sormqr_work*.

4.19.1491 LAPACKE_sormrq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormrq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const float *a, armpl_int_t lda, const float *tau,
                           float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormrq* and *LAPACKE_sormrq*. It also exists with a native Fortran interface as *sormrq*.

4.19.1492 LAPACKE_sormrq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormrq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const float *a,
                                armpl_int_t lda, const float *tau, float *c,
                                armpl_int_t ldc, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormrq_work* and *LAPACKE_sormrq_work*.

4.19.1493 LAPACKE_sormrz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormrz(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           armpl_int_t l, const float *a, armpl_int_t lda,
                           const float *tau, float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormrz* and *LAPACKE_sormrz*. It also exists with a native Fortran interface as *sormrz*.

4.19.1494 LAPACKE_sormrz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormrz_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, armpl_int_t l, const float *a,
                                armpl_int_t lda, const float *tau, float *c,
                                armpl_int_t ldc, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormrz_work* and *LAPACKE_sormrz_work*.

4.19.1495 LAPACKE_sormtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormtr(armpl_int_t matrix_layout, char side, char uplo,
                           char trans, armpl_int_t m, armpl_int_t n,
                           const float *a, armpl_int_t lda, const float *tau,
                           float *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormtr* and *LAPACKE_sormtr*. It also exists with a native Fortran interface as *sormtr*.

4.19.1496 LAPACKE_sormtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sormtr_work(armpl_int_t matrix_layout, char side,
                                char uplo, char trans, armpl_int_t m,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda, const float *tau, float *c,
                                armpl_int_t ldc, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dormtr_work* and *LAPACKE_sormtr_work*.

4.19.1497 LAPACKE_spbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, const float *ab,
                           armpl_int_t ldab, float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbcon*, *LAPACKE_dpbcon*, *LAPACKE_spbcon* and *LAPACKE_zpbcon*. It also exists with a native Fortran interface as *spbcon*.

4.19.1498 LAPACKE_spbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                const float *ab, armpl_int_t ldab,
                                float anorm, float *rcond, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbcon_work*, *LAPACKE_dpbcon_work*, *LAPACKE_spbcon_work* and *LAPACKE_zpbcon_work*.

4.19.1499 LAPACKE_spbequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbequ(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, const float *ab,
                           armpl_int_t ldab, float *s, float *scond,
                           float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbequ*, *LAPACKE_dpbequ*, *LAPACKE_spbequ* and *LAPACKE_zpbequ*. It also exists with a native Fortran interface as *spbequ*.

4.19.1500 LAPACKE_spbequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbequ_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                const float *ab, armpl_int_t ldab, float *s,
                                float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbequ_work*, *LAPACKE_dpbequ_work*, *LAPACKE_spbequ_work* and *LAPACKE_zpbequ_work*.

4.19.1501 LAPACKE_spbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           const float *ab, armpl_int_t ldab,
                           const float *afb, armpl_int_t ldafb,
                           const float *b, armpl_int_t ldb, float *x,
                           armpl_int_t ldx, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbrfs*, *LAPACKE_dpbrfs*, *LAPACKE_spbrfs* and *LAPACKE_zpbrfs*. It also exists with a native Fortran interface as *spbrfs*.

4.19.1502 LAPACKE_spbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs, const float *ab,
                                armpl_int_t ldab, const float *afb,
                                armpl_int_t ldafb, const float *b,
                                armpl_int_t ldb, float *x, armpl_int_t ldx,
                                float *ferr, float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbrfs_work*, *LAPACKE_dpbrfs_work*, *LAPACKE_spbrfs_work* and *LAPACKE_zpbrfs_work*.

4.19.1503 LAPACKE_spbstf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbstf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kb, float *bb,
                           armpl_int_t ldbb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbstf*, *LAPACKE_dpbstf*, *LAPACKE_spbstf* and *LAPACKE_zpbstf*. It also exists with a native Fortran interface as *spbstf*.

4.19.1504 LAPACKE_spbstf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbstf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kb, float *bb,
                                armpl_int_t ldbb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbstf_work*, *LAPACKE_dpbstf_work*, *LAPACKE_spbstf_work* and *LAPACKE_zpbstf_work*.

4.19.1505 LAPACKE_spbsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t kd, armpl_int_t nrhs, float *ab,
                          armpl_int_t ldab, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsv*, *LAPACKE_dpbsv*, *LAPACKE_spbsv* and *LAPACKE_zpbsv*. It also exists with a native Fortran interface as *spbsv*.

4.19.1506 LAPACKE_spbsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t kd,
                               armpl_int_t nrhs, float *ab, armpl_int_t ldab,
                               float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsv_work*, *LAPACKE_dpbsv_work*, *LAPACKE_spbsv_work* and *LAPACKE_zpbsv_work*.

4.19.1507 LAPACKE_spbsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           float *ab, armpl_int_t ldab, float *afb,
                           armpl_int_t ldafb, char *equed, float *s, float *b,
                           armpl_int_t ldb, float *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsvx*, *LAPACKE_dpbsvx*, *LAPACKE_spbsvx* and *LAPACKE_zpbsvx*. It also exists with a native Fortran interface as *spbsvx*.

4.19.1508 LAPACKE_spbsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs, float *ab, armpl_int_t ldab,
                                float *afb, armpl_int_t ldafb, char *equed,
                                float *s, float *b, armpl_int_t ldb, float *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsvx_work*, *LAPACKE_dpbsvx_work*, *LAPACKE_spbsvx_work* and *LAPACKE_zpbsvx_work*.

4.19.1509 LAPACKE_spbtrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbtrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, float *ab,
                           armpl_int_t ldab);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrf*, *LAPACKE_dpbtrf*, *LAPACKE_spbtrf* and *LAPACKE_zpbtrf*. It also exists with a native Fortran interface as *spbtrf*.

4.19.1510 LAPACKE_spbtrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbtrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd, float *ab,
                                armpl_int_t ldab);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrf_work*, *LAPACKE_dpbtrf_work*, *LAPACKE_spbtrf_work* and *LAPACKE_zpbtrf_work*.

4.19.1511 LAPACKE_spbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbtrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           const float *ab, armpl_int_t ldab, float *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrs*, *LAPACKE_dpbtrs*, *LAPACKE_spbtrs* and *LAPACKE_zpbtrs*. It also exists with a native Fortran interface as *spbtrs*.

4.19.1512 LAPACKE_spbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spbtrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs, const float *ab,
                                armpl_int_t ldab, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrs_work*, *LAPACKE_dpbtrs_work*, *LAPACKE_spbtrs_work* and *LAPACKE_zpbtrs_work*.

4.19.1513 LAPACKE_spftrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spftrf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, float *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrf*, *LAPACKE_dpftrf*, *LAPACKE_spftrf* and *LAPACKE_zpftrf*. It also exists with a native Fortran interface as *spftrf*.

4.19.1514 LAPACKE_spftrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spftrf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, float *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrf_work*, *LAPACKE_dpftrf_work*, *LAPACKE_spftrf_work* and *LAPACKE_zpftrf_work*.

4.19.1515 LAPACKE_spftri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spftri(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, float *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftri*, *LAPACKE_dpftri*, *LAPACKE_spftri* and *LAPACKE_zpftri*. It also exists with a native Fortran interface as *spftri*.

4.19.1516 LAPACKE_spftri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spftri_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, float *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftri_work*, *LAPACKE_dpftri_work*, *LAPACKE_spftri_work* and *LAPACKE_zpftri_work*.

4.19.1517 LAPACKE_spftrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spftrs(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *a,
                           float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrs*, *LAPACKE_dpftrs*, *LAPACKE_spftrs* and *LAPACKE_zpftrs*. It also exists with a native Fortran interface as *spftrs*.

4.19.1518 LAPACKE_spftrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spftrs_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const float *a, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrs_work*, *LAPACKE_dpftrs_work*, *LAPACKE_spftrs_work* and *LAPACKE_zpftrs_work*.

4.19.1519 LAPACKE_spocon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spocon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const float *a, armpl_int_t lda,
                           float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpocon*, *LAPACKE_dpocon*, *LAPACKE_spocon* and *LAPACKE_zpocon*. It also exists with a native Fortran interface as *spocon*.

4.19.1520 LAPACKE_spocon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spocon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda, float anorm, float *rcond,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpocon_work*, *LAPACKE_dpocon_work*, *LAPACKE_spocon_work* and *LAPACKE_zpocon_work*.

4.19.1521 LAPACKE_spoequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spoequ(armpl_int_t matrix_layout, armpl_int_t n,
                           const float *a, armpl_int_t lda, float *s,
                           float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequ*, *LAPACKE_dpoequ*, *LAPACKE_spoequ* and *LAPACKE_zpoequ*. It also exists with a native Fortran interface as *spoequ*.

4.19.1522 LAPACKE_spoequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spoequ_work(armpl_int_t matrix_layout, armpl_int_t n,
                                const float *a, armpl_int_t lda, float *s,
                                float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequ_work*, *LAPACKE_dpoequ_work*, *LAPACKE_spoequ_work* and *LAPACKE_zpoequ_work*.

4.19.1523 LAPACKE_spoequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spoequb(armpl_int_t matrix_layout, armpl_int_t n,
                            const float *a, armpl_int_t lda, float *s,
                            float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequb*, *LAPACKE_dpoequb*, *LAPACKE_spoequb* and *LAPACKE_zpoequb*. It also exists with a native Fortran interface as *spoequb*.

4.19.1524 LAPACKE_spoequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spoequb_work(armpl_int_t matrix_layout, armpl_int_t n,
                                 const float *a, armpl_int_t lda, float *s,
                                 float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1525 LAPACKE_sporfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sporfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *a,
                           armpl_int_t lda, const float *af, armpl_int_t ldaf,
                           const float *b, armpl_int_t ldb, float *x,
                           armpl_int_t ldx, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfs*, *LAPACKE_dporfs*, *LAPACKE_sporfs* and *LAPACKE_zporfs*. It also exists with a native Fortran interface as *sporfs*.

4.19.1526 LAPACKE_sporfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sporfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *a, armpl_int_t lda,
                                const float *af, armpl_int_t ldaf,
                                const float *b, armpl_int_t ldb, float *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfs_work*, *LAPACKE_dporfs_work*, *LAPACKE_sporfs_work* and *LAPACKE_zporfs_work*.

4.19.1527 LAPACKE_sporfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sporfsx(armpl_int_t matrix_layout, char uplo, char equed,
                            armpl_int_t n, armpl_int_t nrhs, const float *a,
                            armpl_int_t lda, const float *af,
                            armpl_int_t ldaf, const float *s, const float *b,
                            armpl_int_t ldb, float *x, armpl_int_t ldx,
                            float *rcond, float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfsx*, *LAPACKE_dporfsx*, *LAPACKE_sporfsx* and *LAPACKE_zporfsx*. It also exists with a native Fortran interface as *sporfsx*.

4.19.1528 LAPACKE_sporfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sporfsx_work(armpl_int_t matrix_layout, char uplo,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const float *a, armpl_int_t lda,
                                 const float *af, armpl_int_t ldaf,
                                 const float *s, const float *b,
                                 armpl_int_t ldb, float *x, armpl_int_t ldx,
                                 float *rcond, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, float *work,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfsx_work*, *LAPACKE_dporfsx_work*, *LAPACKE_sporfsx_work* and *LAPACKE_zporfsx_work*.

4.19.1529 LAPACKE_sposv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sposv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, float *a, armpl_int_t lda,
                          float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposv*, *LAPACKE_dposv*, *LAPACKE_sposv* and *LAPACKE_zposv*. It also exists with a native Fortran interface as *sposv*.

4.19.1530 LAPACKE_sposv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sposv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, float *a,
                               armpl_int_t lda, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposv_work*, *LAPACKE_dposv_work*, *LAPACKE_sposv_work* and *LAPACKE_zposv_work*.

4.19.1531 LAPACKE_sposvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sposvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, float *a,
                           armpl_int_t lda, float *af, armpl_int_t ldaf,
                           char *equed, float *s, float *b, armpl_int_t ldb,
                           float *x, armpl_int_t ldx, float *rcond,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposvx*, *LAPACKE_dposvx*, *LAPACKE_sposvx* and *LAPACKE_zposvx*. It also exists with a native Fortran interface as *sposvx*.

4.19.1532 LAPACKE_sposvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sposvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                float *a, armpl_int_t lda, float *af,
                                armpl_int_t ldaf, char *equed, float *s,
                                float *b, armpl_int_t ldb, float *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposvx_work*, *LAPACKE_dposvx_work*, *LAPACKE_sposvx_work* and *LAPACKE_zposvx_work*.

4.19.1533 LAPACKE_sposvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sposvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs, float *a,
                            armpl_int_t lda, float *af, armpl_int_t ldaf,
                            char *equed, float *s, float *b, armpl_int_t ldb,
                            float *x, armpl_int_t ldx, float *rcond,
                            float *rpvgrw, float *berr,
                            armpl_int_t n_err_bnds, float *err_bnds_norm,
                            float *err_bnds_comp, armpl_int_t nparams,
                            float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposvxx*, *LAPACKE_dposvxx*, *LAPACKE_sposvxx* and *LAPACKE_zposvxx*. It also exists with a native Fortran interface as *sposvxx*.

4.19.1534 LAPACKE_sposvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sposvxx_work(armpl_int_t matrix_layout, char fact,
                                 char uplo, armpl_int_t n, armpl_int_t nrhs,
                                 float *a, armpl_int_t lda, float *af,
                                 armpl_int_t ldaf, char *equed, float *s,
                                 float *b, armpl_int_t ldb, float *x,
                                 armpl_int_t ldx, float *rcond, float *rpvgrw,
                                 float *berr, armpl_int_t n_err_bnds,
                                 float *err_bnds_norm, float *err_bnds_comp,
                                 armpl_int_t nparams, float *params,
                                 float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposvxx_work*, *LAPACKE_dposvxx_work*, *LAPACKE_sposvxx_work* and *LAPACKE_zposvxx_work*.

4.19.1535 LAPACKE_spotrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spotrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf*, *LAPACKE_dpotrf*, *LAPACKE_spotrf* and *LAPACKE_zpotrf*. It also exists with a native Fortran interface as *spotrf*.

4.19.1536 LAPACKE_spotrf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spotrf2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf2*, *LAPACKE_dpotrf2*, *LAPACKE_spotrf2* and *LAPACKE_zpotrf2*. It also exists with a native Fortran interface as *spotrf2*.

4.19.1537 LAPACKE_spotrf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spotrf2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf2_work*, *LAPACKE_dpotrf2_work*, *LAPACKE_spotrf2_work* and *LAPACKE_zpotrf2_work*.

4.19.1538 LAPACKE_spotrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spotrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf_work*, *LAPACKE_dpotrf_work*, *LAPACKE_spotrf_work* and *LAPACKE_zpotrf_work*.

4.19.1539 LAPACKE_spotri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spotri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotri*, *LAPACKE_dpotri*, *LAPACKE_spotri* and *LAPACKE_zpotri*. It also exists with a native Fortran interface as *spotri*.

4.19.1540 LAPACKE_spotri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spotri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotri_work*, *LAPACKE_dpotri_work*, *LAPACKE_spotri_work* and *LAPACKE_zpotri_work*.

4.19.1541 LAPACKE_spotrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spotrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrs*, *LAPACKE_dpotrs*, *LAPACKE_spotrs* and *LAPACKE_zpotrs*. It also exists with a native Fortran interface as *spotrs*.

4.19.1542 LAPACKE_spotrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spotrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *a, armpl_int_t lda, float *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrs_work*, *LAPACKE_dpotrs_work*, *LAPACKE_spotrs_work* and *LAPACKE_zpotrs_work*.

4.19.1543 LAPACKE_sppcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sppcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const float *ap, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppcon*, *LAPACKE_dppcon*, *LAPACKE_sppcon* and *LAPACKE_zppcon*. It also exists with a native Fortran interface as *sppcon*.

4.19.1544 LAPACKE_sppcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sppcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const float *ap, float anorm,
                                float *rcond, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppcon_work*, *LAPACKE_dppcon_work*, *LAPACKE_sppcon_work* and *LAPACKE_zppcon_work*.

4.19.1545 LAPACKE_sppequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sppequ(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const float *ap, float *s,
                           float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppequ*, *LAPACKE_dppequ*, *LAPACKE_sppequ* and *LAPACKE_zppequ*. It also exists with a native Fortran interface as *sppequ*.

4.19.1546 LAPACKE_sppequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sppequ_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const float *ap, float *s,
                                float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppequ_work*, *LAPACKE_dppequ_work*, *LAPACKE_sppequ_work* and *LAPACKE_zppequ_work*.

4.19.1547 LAPACKE_spprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *ap,
                           const float *afp, const float *b, armpl_int_t ldb,
                           float *x, armpl_int_t ldx, float *ferr,
                           float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpprfs*, *LAPACKE_dpprfs*, *LAPACKE_spprfs* and *LAPACKE_zpprfs*. It also exists with a native Fortran interface as *spprfs*.

4.19.1548 LAPACKE_spprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *ap, const float *afp,
                                const float *b, armpl_int_t ldb, float *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpprfs_work*, *LAPACKE_dpprfs_work*, *LAPACKE_spprfs_work* and *LAPACKE_zpprfs_work*.

4.19.1549 LAPACKE_sppsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sppsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, float *ap, float *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsv*, *LAPACKE_dppsv*, *LAPACKE_sppsv* and *LAPACKE_zppsv*. It also exists with a native Fortran interface as *sppsv*.

4.19.1550 LAPACKE_sppsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sppsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, float *ap,
                               float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsv_work*, *LAPACKE_dppsv_work*, *LAPACKE_sppsv_work* and *LAPACKE_zppsv_work*.

4.19.1551 LAPACKE_sppsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sppsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, float *ap,
                           float *afp, char *equed, float *s, float *b,
                           armpl_int_t ldb, float *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsvx*, *LAPACKE_dppsvx*, *LAPACKE_sppsvx* and *LAPACKE_zppsvx*. It also exists with a native Fortran interface as *sppsvx*.

4.19.1552 LAPACKE_sppsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sppsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                float *ap, float *afp, char *equed, float *s,
                                float *b, armpl_int_t ldb, float *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsvx_work*, *LAPACKE_dppsvx_work*, *LAPACKE_sppsvx_work* and *LAPACKE_zppsvx_work*.

4.19.1553 LAPACKE_spptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrf*, *LAPACKE_dpptrf*, *LAPACKE_spptrf* and *LAPACKE_zpptrf*. It also exists with a native Fortran interface as *spptrf*.

4.19.1554 LAPACKE_spptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrf_work*, *LAPACKE_dpptrf_work*, *LAPACKE_spptrf_work* and *LAPACKE_zpptrf_work*.

4.19.1555 LAPACKE_spptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptri*, *LAPACKE_dpptri*, *LAPACKE_spptri* and *LAPACKE_zpptri*. It also exists with a native Fortran interface as *spptri*.

4.19.1556 LAPACKE_spptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptri_work*, *LAPACKE_dpptri_work*, *LAPACKE_spptri_work* and *LAPACKE_zpptri_work*.

4.19.1557 LAPACKE_spptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *ap,
                           float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrs*, *LAPACKE_dpptrs*, *LAPACKE_spptrs* and *LAPACKE_zpptrs*. It also exists with a native Fortran interface as *spptrs*.

4.19.1558 LAPACKE_spptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *ap, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrs_work*, *LAPACKE_dpptrs_work*, *LAPACKE_spptrs_work* and *LAPACKE_zpptrs_work*.

4.19.1559 LAPACKE_spstrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spstrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           armpl_int_t *piv, armpl_int_t *rank, float tol);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpstrf*, *LAPACKE_dpstrf*, *LAPACKE_spstrf* and *LAPACKE_zpstrf*. It also exists with a native Fortran interface as *spstrf*.

4.19.1560 LAPACKE_spstrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spstrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                armpl_int_t *piv, armpl_int_t *rank,
                                float tol, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpstrf_work*, *LAPACKE_dpstrf_work*, *LAPACKE_spstrf_work* and *LAPACKE_zpstrf_work*.

4.19.1561 LAPACKE_sptcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sptcon(armpl_int_t n, const float *d, const float *e,
                           float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptcon*, *LAPACKE_dptcon*, *LAPACKE_sptcon* and *LAPACKE_zptcon*. It also exists with a native Fortran interface as *sptcon*.

4.19.1562 LAPACKE_sptcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sptcon_work(armpl_int_t n, const float *d, const float *e,
                                float anorm, float *rcond, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptcon_work*, *LAPACKE_dptcon_work*, *LAPACKE_sptcon_work* and *LAPACKE_zptcon_work*.

4.19.1563 LAPACKE_spteqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spteqr(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, float *d, float *e, float *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpteqr*, *LAPACKE_dpteqr*, *LAPACKE_spteqr* and *LAPACKE_zpteqr*. It also exists with a native Fortran interface as *spteqr*.

4.19.1564 LAPACKE_spteqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spteqr_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, float *d, float *e, float *z,
                                armpl_int_t ldz, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpteqr_work*, *LAPACKE_dpteqr_work*, *LAPACKE_spteqr_work* and *LAPACKE_zpteqr_work*.

4.19.1565 LAPACKE_sptrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sptrfs(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t nrhs, const float *d, const float *e,
                           const float *df, const float *ef, const float *b,
                           armpl_int_t ldb, float *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptrfs*, *LAPACKE_dptrfs*, *LAPACKE_sptrfs* and *LAPACKE_zptrfs*. It also exists with a native Fortran interface as *sptrfs*.

4.19.1566 LAPACKE_sptrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sptrfs_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t nrhs, const float *d,
                                const float *e, const float *df,
                                const float *ef, const float *b,
                                armpl_int_t ldb, float *x, armpl_int_t ldx,
                                float *ferr, float *berr, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptrfs_work*, *LAPACKE_dptrfs_work*, *LAPACKE_sptrfs_work* and *LAPACKE_zptrfs_work*.

4.19.1567 LAPACKE_sptsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sptsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, float *d, float *e, float *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsv*, *LAPACKE_dptsv*, *LAPACKE_sptsv* and *LAPACKE_zptsv*. It also exists with a native Fortran interface as *sptsv*.

4.19.1568 LAPACKE_sptsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sptsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, float *d, float *e, float *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsv_work*, *LAPACKE_dptsv_work*, *LAPACKE_sptsv_work* and *LAPACKE_zptsv_work*.

4.19.1569 LAPACKE_sptsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sptsvx(armpl_int_t matrix_layout, char fact,
                           armpl_int_t n, armpl_int_t nrhs, const float *d,
                           const float *e, float *df, float *ef,
                           const float *b, armpl_int_t ldb, float *x,
                           armpl_int_t ldx, float *rcond, float *ferr,
                           float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsvx*, *LAPACKE_dptsvx*, *LAPACKE_sptsvx* and *LAPACKE_zptsvx*. It also exists with a native Fortran interface as *sptsvx*.

4.19.1570 LAPACKE_sptsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sptsvx_work(armpl_int_t matrix_layout, char fact,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *d, const float *e, float *df,
                                float *ef, const float *b, armpl_int_t ldb,
                                float *x, armpl_int_t ldx, float *rcond,
                                float *ferr, float *berr, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsvx_work*, *LAPACKE_dptsvx_work*, *LAPACKE_sptsvx_work* and *LAPACKE_zptsvx_work*.

4.19.1571 LAPACKE_spttrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spttrf(armpl_int_t n, float *d, float *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrf*, *LAPACKE_dpttrf*, *LAPACKE_spttrf* and *LAPACKE_zpttrf*. It also exists with a native Fortran interface as *spttrf*.

4.19.1572 LAPACKE_spttrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spttrf_work(armpl_int_t n, float *d, float *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrf_work*, *LAPACKE_dpttrf_work*, *LAPACKE_spttrf_work* and *LAPACKE_zpttrf_work*.

4.19.1573 LAPACKE_spttrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spttrs(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t nrhs, const float *d, const float *e,
                           float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrs*, *LAPACKE_dpttrs*, *LAPACKE_spttrs* and *LAPACKE_zpttrs*. It also exists with a native Fortran interface as *spttrs*.

4.19.1574 LAPACKE_spttrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_spttrs_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t nrhs, const float *d,
                                const float *e, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrs_work*, *LAPACKE_dpttrs_work*, *LAPACKE_spttrs_work* and *LAPACKE_zpttrs_work*.

4.19.1575 LAPACKE_ssbev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_int_t kd, float *ab,
                          armpl_int_t ldab, float *w, float *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbev* and *LAPACKE_ssbev*. It also exists with a native Fortran interface as *ssbev*.

4.19.1576 LAPACKE_ssbev_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbev_2stage(armpl_int_t matrix_layout, char jobz,
                                 char uplo, armpl_int_t n, armpl_int_t kd,
                                 float *ab, armpl_int_t ldab, float *w,
                                 float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbev_2stage* and *LAPACKE_ssbev_2stage*. It also exists with a native Fortran interface as *ssbev_2stage*.

4.19.1577 LAPACKE_ssbev_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbev_2stage_work(armpl_int_t matrix_layout, char jobz,
                                      char uplo, armpl_int_t n,
                                      armpl_int_t kd, float *ab,
                                      armpl_int_t ldab, float *w, float *z,
                                      armpl_int_t ldz, float *work,
                                      armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbev_2stage_work* and *LAPACKE_ssbev_2stage_work*.

4.19.1578 LAPACKE_ssbev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, armpl_int_t kd,
                               float *ab, armpl_int_t ldab, float *w,
                               float *z, armpl_int_t ldz, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbev_work* and *LAPACKE_ssbev_work*.

4.19.1579 LAPACKE_ssbevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_int_t kd, float *ab,
                           armpl_int_t ldab, float *w, float *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevd* and *LAPACKE_ssbevd*. It also exists with a native Fortran interface as *ssbevd*.

4.19.1580 LAPACKE_ssbevd_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbevd_2stage(armpl_int_t matrix_layout, char jobz,
                                  char uplo, armpl_int_t n, armpl_int_t kd,
                                  float *ab, armpl_int_t ldab, float *w,
                                  float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevd_2stage* and *LAPACKE_ssbevd_2stage*. It also exists with a native Fortran interface as *ssbevd_2stage*.

4.19.1581 LAPACKE_ssbevd_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbevd_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char uplo, armpl_int_t n,
                                       armpl_int_t kd, float *ab,
                                       armpl_int_t ldab, float *w, float *z,
                                       armpl_int_t ldz, float *work,
                                       armpl_int_t lwork, armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevd_2stage_work* and *LAPACKE_ssbevd_2stage_work*.

4.19.1582 LAPACKE_ssbevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                float *ab, armpl_int_t ldab, float *w,
                                float *z, armpl_int_t ldz, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevd_work* and *LAPACKE_ssbevd_work*.

4.19.1583 LAPACKE_ssbevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_int_t kd,
                           float *ab, armpl_int_t ldab, float *q,
                           armpl_int_t ldq, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevx* and *LAPACKE_ssbevx*. It also exists with a native Fortran interface as *ssbevx*.

4.19.1584 LAPACKE_ssbevx_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbevx_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  armpl_int_t kd, float *ab, armpl_int_t ldab,
                                  float *q, armpl_int_t ldq, float vl,
                                  float vu, armpl_int_t il, armpl_int_t iu,
                                  float abstol, armpl_int_t *m, float *w,
                                  float *z, armpl_int_t ldz,
                                  armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevx_2stage* and *LAPACKE_ssbevx_2stage*. It also exists with a native Fortran interface as *ssbevx_2stage*.

4.19.1585 LAPACKE_ssbevx_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbevx_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       armpl_int_t kd, float *ab,
                                       armpl_int_t ldab, float *q,
                                       armpl_int_t ldq, float vl, float vu,
                                       armpl_int_t il, armpl_int_t iu,
                                       float abstol, armpl_int_t *m, float *w,
                                       float *z, armpl_int_t ldz, float *work,
                                       armpl_int_t lwork, armpl_int_t *iwork,
                                       armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

For this routine in other precisions, please see *LAPACKE_dsbevx_2stage_work* and *LAPACKE_ssbevx_2stage_work*.

4.19.1586 LAPACKE_ssbevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_int_t kd, float *ab, armpl_int_t ldab,
                                float *q, armpl_int_t ldq, float vl, float vu,
                                armpl_int_t il, armpl_int_t iu, float abstol,
                                armpl_int_t *m, float *w, float *z,
                                armpl_int_t ldz, float *work,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbevx_work* and *LAPACKE_ssbevx_work*.

4.19.1587 LAPACKE_ssbgst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbgst(armpl_int_t matrix_layout, char vect, char uplo,
                           armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                           float *ab, armpl_int_t ldab, const float *bb,
                           armpl_int_t ldbb, float *x, armpl_int_t ldx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgst* and *LAPACKE_ssbgst*. It also exists with a native Fortran interface as *ssbgst*.

4.19.1588 LAPACKE_ssbgst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbgst_work(armpl_int_t matrix_layout, char vect,
                                char uplo, armpl_int_t n, armpl_int_t ka,
                                armpl_int_t kb, float *ab, armpl_int_t ldab,
                                const float *bb, armpl_int_t ldbb, float *x,
                                armpl_int_t ldx, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgst_work* and *LAPACKE_ssbgst_work*.

4.19.1589 LAPACKE_ssbgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbgv(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                          float *ab, armpl_int_t ldab, float *bb,
                          armpl_int_t ldbb, float *w, float *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgv* and *LAPACKE_ssbgv*. It also exists with a native Fortran interface as *ssbgv*.

4.19.1590 LAPACKE_ssbgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbgv_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, armpl_int_t ka,
                               armpl_int_t kb, float *ab, armpl_int_t ldab,
                               float *bb, armpl_int_t ldbb, float *w,
                               float *z, armpl_int_t ldz, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgv_work* and *LAPACKE_ssbgv_work*.

4.19.1591 LAPACKE_ssbgvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbgvd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                           float *ab, armpl_int_t ldab, float *bb,
                           armpl_int_t ldbb, float *w, float *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgvd* and *LAPACKE_ssbgvd*. It also exists with a native Fortran interface as *ssbgvd*.

4.19.1592 LAPACKE_ssbgvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbgvd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, armpl_int_t ka,
                                armpl_int_t kb, float *ab, armpl_int_t ldab,
                                float *bb, armpl_int_t ldbb, float *w,
                                float *z, armpl_int_t ldz, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgvd_work* and *LAPACKE_ssbgvd_work*.

4.19.1593 LAPACKE_ssbgvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbgvx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_int_t ka,
                           armpl_int_t kb, float *ab, armpl_int_t ldab,
                           float *bb, armpl_int_t ldbb, float *q,
                           armpl_int_t ldq, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgvx* and *LAPACKE_ssbgvx*. It also exists with a native Fortran interface as *ssbgvx*.

4.19.1594 LAPACKE_ssbgvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbgvx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_int_t ka, armpl_int_t kb, float *ab,
                                armpl_int_t ldab, float *bb, armpl_int_t ldbb,
                                float *q, armpl_int_t ldq, float vl, float vu,
                                armpl_int_t il, armpl_int_t iu, float abstol,
                                armpl_int_t *m, float *w, float *z,
                                armpl_int_t ldz, float *work,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbgvx_work* and *LAPACKE_ssbgvx_work*.

4.19.1595 LAPACKE_ssbtrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbtrd(armpl_int_t matrix_layout, char vect, char uplo,
                           armpl_int_t n, armpl_int_t kd, float *ab,
                           armpl_int_t ldab, float *d, float *e, float *q,
                           armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbtrd* and *LAPACKE_ssbtrd*. It also exists with a native Fortran interface as *ssbtrd*.

4.19.1596 LAPACKE_ssbtrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssbtrd_work(armpl_int_t matrix_layout, char vect,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                float *ab, armpl_int_t ldab, float *d,
                                float *e, float *q, armpl_int_t ldq,
                                float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsbtrd_work* and *LAPACKE_ssbtrd_work*.

4.19.1597 LAPACKE_ssfrk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssfrk(armpl_int_t matrix_layout, char transr, char uplo,
                          char trans, armpl_int_t n, armpl_int_t k,
                          float alpha, const float *a, armpl_int_t lda,
                          float beta, float *c);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsfrk* and *LAPACKE_ssfrk*. It also exists with a native Fortran interface as *ssfrk*.

4.19.1598 LAPACKE_ssfrk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssfrk_work(armpl_int_t matrix_layout, char transr,
                               char uplo, char trans, armpl_int_t n,
                               armpl_int_t k, float alpha, const float *a,
                               armpl_int_t lda, float beta, float *c);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsfrk_work* and *LAPACKE_ssfrk_work*.

4.19.1599 LAPACKE_sspcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const float *ap,
                           const armpl_int_t *ipiv, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspcon*, *LAPACKE_dspcon*, *LAPACKE_sspcon* and *LAPACKE_zspcon*. It also exists with a native Fortran interface as *sspcon*.

4.19.1600 LAPACKE_sspcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const float *ap,
                                const armpl_int_t *ipiv, float anorm,
                                float *rcond, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspcon_work*, *LAPACKE_dspcon_work*, *LAPACKE_sspcon_work* and *LAPACKE_zspcon_work*.

4.19.1601 LAPACKE_sspev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, float *ap, float *w, float *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1602 LAPACKE_sspev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, float *ap, float *w,
                               float *z, armpl_int_t ldz, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspev_work* and *LAPACKE_sspev_work*.

4.19.1603 LAPACKE_sspevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, float *ap, float *w, float *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspevd* and *LAPACKE_sspevd*. It also exists with a native Fortran interface as *sspevd*.

4.19.1604 LAPACKE_sspevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, float *ap, float *w,
                                float *z, armpl_int_t ldz, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspevd_work* and *LAPACKE_sspevd_work*.

4.19.1605 LAPACKE_sspevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, float *ap, float vl,
                           float vu, armpl_int_t il, armpl_int_t iu,
                           float abstol, armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspevx* and *LAPACKE_sspevx*. It also exists with a native Fortran interface as *sspevx*.

4.19.1606 LAPACKE_sspevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                float *ap, float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, float abstol, armpl_int_t *m,
                                float *w, float *z, armpl_int_t ldz,
                                float *work, armpl_int_t *iwork,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspevx_work* and *LAPACKE_sspevx_work*.

4.19.1607 LAPACKE_sspgst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspgst(armpl_int_t matrix_layout, armpl_int_t itype,
                           char uplo, armpl_int_t n, float *ap,
                           const float *bp);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgst* and *LAPACKE_sspgst*. It also exists with a native Fortran interface as *sspgst*.

4.19.1608 LAPACKE_sspgst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspgst_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char uplo, armpl_int_t n, float *ap,
                                const float *bp);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgst_work* and *LAPACKE_sspgst_work*.

4.19.1609 LAPACKE_sspgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspgv(armpl_int_t matrix_layout, armpl_int_t itype,
                          char jobz, char uplo, armpl_int_t n, float *ap,
                          float *bp, float *w, float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgv* and *LAPACKE_sspgv*. It also exists with a native Fortran interface as *sspgv*.

4.19.1610 LAPACKE_sspgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspgv_work(armpl_int_t matrix_layout, armpl_int_t itype,
                               char jobz, char uplo, armpl_int_t n, float *ap,
                               float *bp, float *w, float *z, armpl_int_t ldz,
                               float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgv_work* and *LAPACKE_sspgv_work*.

4.19.1611 LAPACKE_sspgvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspgvd(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char uplo, armpl_int_t n, float *ap,
                           float *bp, float *w, float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgvd* and *LAPACKE_sspgvd*. It also exists with a native Fortran interface as *sspgvd*.

4.19.1612 LAPACKE_sspgvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspgvd_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char uplo, armpl_int_t n,
                                float *ap, float *bp, float *w, float *z,
                                armpl_int_t ldz, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgvd_work* and *LAPACKE_sspgvd_work*.

4.19.1613 LAPACKE_sspgvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspgvx(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char range, char uplo, armpl_int_t n,
                           float *ap, float *bp, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgvx* and *LAPACKE_sspgvx*. It also exists with a native Fortran interface as *sspgvx*.

4.19.1614 LAPACKE_sspgvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspgvx_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char range, char uplo,
                                armpl_int_t n, float *ap, float *bp, float vl,
                                float vu, armpl_int_t il, armpl_int_t iu,
                                float abstol, armpl_int_t *m, float *w,
                                float *z, armpl_int_t ldz, float *work,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dspgvx_work* and *LAPACKE_sspgvx_work*.

4.19.1615 LAPACKE_ssprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *ap,
                           const float *afp, const armpl_int_t *ipiv,
                           const float *b, armpl_int_t ldb, float *x,
                           armpl_int_t ldx, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csprfs*, *LAPACKE_dsprfs*, *LAPACKE_ssprfs* and *LAPACKE_zsprfs*. It also exists with a native Fortran interface as *ssprfs*.

4.19.1616 LAPACKE_ssprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *ap, const float *afp,
                                const armpl_int_t *ipiv, const float *b,
                                armpl_int_t ldb, float *x, armpl_int_t ldx,
                                float *ferr, float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csprfs_work*, *LAPACKE_dsprfs_work*, *LAPACKE_ssprfs_work* and *LAPACKE_zsprfs_work*.

4.19.1617 LAPACKE_sspsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, float *ap, armpl_int_t *ipiv,
                          float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsv*, *LAPACKE_dspsv*, *LAPACKE_sspsv* and *LAPACKE_zspsv*. It also exists with a native Fortran interface as *sspsv*.

4.19.1618 LAPACKE_sspsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, float *ap,
                               armpl_int_t *ipiv, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsv_work*, *LAPACKE_dspsv_work*, *LAPACKE_sspsv_work* and *LAPACKE_zspsv_work*.

4.19.1619 LAPACKE_sspsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *ap,
                           float *afp, armpl_int_t *ipiv, const float *b,
                           armpl_int_t ldb, float *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsvx*, *LAPACKE_dspsvx*, *LAPACKE_sspsvx* and *LAPACKE_zspsvx*. It also exists with a native Fortran interface as *sspsvx*.

4.19.1620 LAPACKE_sspsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sspsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const float *ap, float *afp,
                                armpl_int_t *ipiv, const float *b,
                                armpl_int_t ldb, float *x, armpl_int_t ldx,
                                float *rcond, float *ferr, float *berr,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsvx_work*, *LAPACKE_dspsvx_work*, *LAPACKE_sspsvx_work* and *LAPACKE_zspsvx_work*.

4.19.1621 LAPACKE_ssptrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssptrd(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *ap, float *d, float *e,
                           float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsptrd* and *LAPACKE_ssptrd*. It also exists with a native Fortran interface as *ssptrd*.

4.19.1622 LAPACKE_ssptrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssptrd_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *ap, float *d, float *e,
                                float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsptrd_work* and *LAPACKE_ssptrd_work*.

4.19.1623 LAPACKE_ssptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *ap, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrf*, *LAPACKE_dsptrf*, *LAPACKE_ssptrf* and *LAPACKE_zsptrf*. It also exists with a native Fortran interface as *ssptrf*.

4.19.1624 LAPACKE_ssptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *ap, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrf_work*, *LAPACKE_dsptrf_work*, *LAPACKE_ssptrf_work* and *LAPACKE_zsptrf_work*.

4.19.1625 LAPACKE_ssptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *ap,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptri*, *LAPACKE_dsptri*, *LAPACKE_ssptri* and *LAPACKE_zsptri*. It also exists with a native Fortran interface as *ssptri*.

4.19.1626 LAPACKE_ssptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *ap,
                                const armpl_int_t *ipiv, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptri_work*, *LAPACKE_dsptri_work*, *LAPACKE_ssptri_work* and *LAPACKE_zsptri_work*.

4.19.1627 LAPACKE_ssptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *ap,
                           const armpl_int_t *ipiv, float *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrs*, *LAPACKE_dsptrs*, *LAPACKE_ssptrs* and *LAPACKE_zsptrs*. It also exists with a native Fortran interface as *ssptrs*.

4.19.1628 LAPACKE_ssptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *ap, const armpl_int_t *ipiv,
                                float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrs_work*, *LAPACKE_dsptrs_work*, *LAPACKE_ssptrs_work* and *LAPACKE_zsptrs_work*.

4.19.1629 LAPACKE_sstebz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstebz(char range, char order, armpl_int_t n, float vl,
                           float vu, armpl_int_t il, armpl_int_t iu,
                           float abstol, const float *d, const float *e,
                           armpl_int_t *m, armpl_int_t *nsplit, float *w,
                           armpl_int_t *iblock, armpl_int_t *isplit);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1630 LAPACKE_sstebz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstebz_work(char range, char order, armpl_int_t n,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, float abstol, const float *d,
                                const float *e, armpl_int_t *m,
                                armpl_int_t *nsplit, float *w,
                                armpl_int_t *iblock, armpl_int_t *isplit,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstebz_work* and *LAPACKE_sstebz_work*.

4.19.1631 LAPACKE_sstedc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstedc(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, float *d, float *e, float *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstedc*, *LAPACKE_dstedc*, *LAPACKE_sstedc* and *LAPACKE_zstedc*. It also exists with a native Fortran interface as *sstedc*.

4.19.1632 LAPACKE_sstedc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstedc_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, float *d, float *e, float *z,
                                armpl_int_t ldz, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1633 LAPACKE_sstegr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstegr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, float *d, float *e, float vl,
                           float vu, armpl_int_t il, armpl_int_t iu,
                           float abstol, armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstegr*, *LAPACKE_dstegr*, *LAPACKE_sstegr* and *LAPACKE_zstegr*. It also exists with a native Fortran interface as *sstegr*.

4.19.1634 LAPACKE_sstegr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstegr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, float *d, float *e,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, float abstol, armpl_int_t *m,
                                float *w, float *z, armpl_int_t ldz,
                                armpl_int_t *isuppz, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstegr_work*, *LAPACKE_dstegr_work*, *LAPACKE_sstegr_work* and *LAPACKE_zstegr_work*.

4.19.1635 LAPACKE_sstein

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstein(armpl_int_t matrix_layout, armpl_int_t n,
                           const float *d, const float *e, armpl_int_t m,
                           const float *w, const armpl_int_t *iblock,
                           const armpl_int_t *isplit, float *z,
                           armpl_int_t ldz, armpl_int_t *ifailv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstein*, *LAPACKE_dstein*, *LAPACKE_sstein* and *LAPACKE_zstein*. It also exists with a native Fortran interface as *sstein*.

4.19.1636 LAPACKE_sstein_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstein_work(armpl_int_t matrix_layout, armpl_int_t n,
                                const float *d, const float *e, armpl_int_t m,
                                const float *w, const armpl_int_t *iblock,
                                const armpl_int_t *isplit, float *z,
                                armpl_int_t ldz, float *work,
                                armpl_int_t *iwork, armpl_int_t *ifailv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstein_work*, *LAPACKE_dstein_work*, *LAPACKE_sstein_work* and *LAPACKE_zstein_work*.

4.19.1637 LAPACKE_sstemr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstemr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, float *d, float *e, float vl,
                           float vu, armpl_int_t il, armpl_int_t iu,
                           armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t nzc,
                           armpl_int_t *isuppz, armpl_int_t *tryrac);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstemr*, *LAPACKE_dstemr*, *LAPACKE_sstemr* and *LAPACKE_zstemr*. It also exists with a native Fortran interface as *sstemr*.

4.19.1638 LAPACKE_sstemr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstemr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, float *d, float *e,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, armpl_int_t *m, float *w,
                                float *z, armpl_int_t ldz, armpl_int_t nzc,
                                armpl_int_t *isuppz, armpl_int_t *tryrac,
                                float *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstemr_work*, *LAPACKE_dstemr_work*, *LAPACKE_sstemr_work* and *LAPACKE_zstemr_work*.

4.19.1639 LAPACKE_ssteqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssteqr(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, float *d, float *e, float *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csteqr*, *LAPACKE_dsteqr*, *LAPACKE_ssteqr* and *LAPACKE_zsteqr*. It also exists with a native Fortran interface as *ssteqr*.

4.19.1640 LAPACKE_ssteqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssteqr_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, float *d, float *e, float *z,
                                armpl_int_t ldz, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csteqr_work*, *LAPACKE_dsteqr_work*, *LAPACKE_ssteqr_work* and *LAPACKE_zsteqr_work*.

4.19.1641 LAPACKE_ssterf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssterf(armpl_int_t n, float *d, float *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsterf* and *LAPACKE_ssterf*. It also exists with a native Fortran interface as *ssterf*.

4.19.1642 LAPACKE_ssterf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssterf_work(armpl_int_t n, float *d, float *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsterf_work* and *LAPACKE_ssterf_work*.

4.19.1643 LAPACKE_sstev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstev(armpl_int_t matrix_layout, char jobz, armpl_int_t n,
                          float *d, float *e, float *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstev* and *LAPACKE_sstev*. It also exists with a native Fortran interface as *sstev*.

4.19.1644 LAPACKE_sstev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstev_work(armpl_int_t matrix_layout, char jobz,
                               armpl_int_t n, float *d, float *e, float *z,
                               armpl_int_t ldz, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstev_work* and *LAPACKE_sstev_work*.

4.19.1645 LAPACKE_sstevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstevd(armpl_int_t matrix_layout, char jobz,
                           armpl_int_t n, float *d, float *e, float *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevd* and *LAPACKE_sstevd*. It also exists with a native Fortran interface as *sstevd*.

4.19.1646 LAPACKE_sstevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstevd_work(armpl_int_t matrix_layout, char jobz,
                                armpl_int_t n, float *d, float *e, float *z,
                                armpl_int_t ldz, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevd_work* and *LAPACKE_sstevd_work*.

4.19.1647 LAPACKE_sstevr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstevr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, float *d, float *e, float vl,
                           float vu, armpl_int_t il, armpl_int_t iu,
                           float abstol, armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevr* and *LAPACKE_sstevr*. It also exists with a native Fortran interface as *sstevr*.

4.19.1648 LAPACKE_sstevr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstevr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, float *d, float *e,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, float abstol, armpl_int_t *m,
                                float *w, float *z, armpl_int_t ldz,
                                armpl_int_t *isuppz, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevr_work* and *LAPACKE_sstevr_work*.

4.19.1649 LAPACKE_sstevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstevx(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, float *d, float *e, float vl,
                           float vu, armpl_int_t il, armpl_int_t iu,
                           float abstol, armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevx* and *LAPACKE_sstevx*. It also exists with a native Fortran interface as *sstevx*.

4.19.1650 LAPACKE_sstevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_sstevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, float *d, float *e,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, float abstol, armpl_int_t *m,
                                float *w, float *z, armpl_int_t ldz,
                                float *work, armpl_int_t *iwork,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dstevx_work* and *LAPACKE_sstevx_work*.

4.19.1651 LAPACKE_ssycon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssycon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const float *a, armpl_int_t lda,
                           const armpl_int_t *ipiv, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon*, *LAPACKE_dsycon*, *LAPACKE_ssycon* and *LAPACKE_zsycon*. It also exists with a native Fortran interface as *ssycon*.

4.19.1652 LAPACKE_ssycon_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssycon_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, const float *a, armpl_int_t lda,
                             const float *e, const armpl_int_t *ipiv,
                             float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_3*, *LAPACKE_dsycon_3*, *LAPACKE_ssycon_3* and *LAPACKE_zsycon_3*. It also exists with a native Fortran interface as *ssycon_3*.

4.19.1653 LAPACKE_ssycon_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssycon_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, const float *a,
                                  armpl_int_t lda, const float *e,
                                  const armpl_int_t *ipiv, float anorm,
                                  float *rcond, float *work,
                                  armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_3_work*, *LAPACKE_dsycon_3_work*, *LAPACKE_ssycon_3_work* and *LAPACKE_zsycon_3_work*.

4.19.1654 LAPACKE_ssycon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssycon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                float anorm, float *rcond, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_work*, *LAPACKE_dsycon_work*, *LAPACKE_ssycon_work* and *LAPACKE_zsycon_work*.

4.19.1655 LAPACKE_ssyconv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyconv(armpl_int_t matrix_layout, char uplo, char way,
                            armpl_int_t n, float *a, armpl_int_t lda,
                            const armpl_int_t *ipiv, float *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyconv*, *LAPACKE_dsyconv*, *LAPACKE_ssyconv* and *LAPACKE_zsyconv*. It also exists with a native Fortran interface as *ssyconv*.

4.19.1656 LAPACKE_ssyconv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyconv_work(armpl_int_t matrix_layout, char uplo,
                                 char way, armpl_int_t n, float *a,
                                 armpl_int_t lda, const armpl_int_t *ipiv,
                                 float *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyconv_work*, *LAPACKE_dsyconv_work*, *LAPACKE_ssyconv_work* and *LAPACKE_zsyconv_work*.

4.19.1657 LAPACKE_ssyequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyequb(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, const float *a, armpl_int_t lda,
                            float *s, float *scond, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyequb*, *LAPACKE_dsyequb*, *LAPACKE_ssyequb* and *LAPACKE_zsyequb*. It also exists with a native Fortran interface as *ssyequb*.

4.19.1658 LAPACKE_ssyequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyequb_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, const float *a,
                                 armpl_int_t lda, float *s, float *scond,
                                 float *amax, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyequb_work*, *LAPACKE_dsyequb_work*, *LAPACKE_ssyequb_work* and *LAPACKE_zsyequb_work*.

4.19.1659 LAPACKE_ssyev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, float *a, armpl_int_t lda,
                          float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyev* and *LAPACKE_ssyev*. It also exists with a native Fortran interface as *ssyev*.

4.19.1660 LAPACKE_ssyev_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyev_2stage(armpl_int_t matrix_layout, char jobz,
                                 char uplo, armpl_int_t n, float *a,
                                 armpl_int_t lda, float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyev_2stage* and *LAPACKE_ssyev_2stage*. It also exists with a native Fortran interface as *ssyev_2stage*.

4.19.1661 LAPACKE_ssyev_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyev_2stage_work(armpl_int_t matrix_layout, char jobz,
                                      char uplo, armpl_int_t n, float *a,
                                      armpl_int_t lda, float *w, float *work,
                                      armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyev_2stage_work* and *LAPACKE_ssyev_2stage_work*.

4.19.1662 LAPACKE_ssyev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, float *a,
                               armpl_int_t lda, float *w, float *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyev_work* and *LAPACKE_ssyev_work*.

4.19.1663 LAPACKE_ssyevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevd* and *LAPACKE_ssyevd*. It also exists with a native Fortran interface as *ssyevd*.

4.19.1664 LAPACKE_ssyevd_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevd_2stage(armpl_int_t matrix_layout, char jobz,
                                  char uplo, armpl_int_t n, float *a,
                                  armpl_int_t lda, float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevd_2stage* and *LAPACKE_ssyevd_2stage*. It also exists with a native Fortran interface as *ssyevd_2stage*.

4.19.1665 LAPACKE_ssyevd_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevd_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char uplo, armpl_int_t n, float *a,
                                       armpl_int_t lda, float *w, float *work,
                                       armpl_int_t lwork, armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevd_2stage_work* and *LAPACKE_ssyevd_2stage_work*.

4.19.1666 LAPACKE_ssyevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, float *a,
                                armpl_int_t lda, float *w, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevd_work* and *LAPACKE_ssyevd_work*.

4.19.1667 LAPACKE_ssyevr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevr(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, float *a,
                           armpl_int_t lda, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevr* and *LAPACKE_ssyevr*. It also exists with a native Fortran interface as *ssyevr*.

4.19.1668 LAPACKE_ssyevr_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevr_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  float *a, armpl_int_t lda, float vl,
                                  float vu, armpl_int_t il, armpl_int_t iu,
```

(continues on next page)

(continued from previous page)

```
                                    float abstol, armpl_int_t *m, float *w,
                                    float *z, armpl_int_t ldz,
                                    armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevr_2stage* and *LAPACKE_ssyevr_2stage*. It also exists with a native Fortran interface as *ssyevr_2stage*.

4.19.1669 LAPACKE_ssyevr_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevr_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       float *a, armpl_int_t lda, float vl,
                                       float vu, armpl_int_t il,
                                       armpl_int_t iu, float abstol,
                                       armpl_int_t *m, float *w, float *z,
                                       armpl_int_t ldz, armpl_int_t *isuppz,
                                       float *work, armpl_int_t lwork,
                                       armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1670 LAPACKE_ssyevr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevr_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                float *a, armpl_int_t lda, float vl, float vu,
                                armpl_int_t il, armpl_int_t iu, float abstol,
                                armpl_int_t *m, float *w, float *z,
                                armpl_int_t ldz, armpl_int_t *isuppz,
                                float *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevr_work* and *LAPACKE_ssyevr_work*.

4.19.1671 LAPACKE_ssyevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, float *a,
                           armpl_int_t lda, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevx* and *LAPACKE_ssyevx*. It also exists with a native Fortran interface as *ssyevx*.

4.19.1672 LAPACKE_ssyevx_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevx_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  float *a, armpl_int_t lda, float vl,
                                  float vu, armpl_int_t il, armpl_int_t iu,
                                  float abstol, armpl_int_t *m, float *w,
                                  float *z, armpl_int_t ldz,
                                  armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsyevx_2stage* and *LAPACKE_ssyevx_2stage*. It also exists with a native Fortran interface as *ssyevx_2stage*.

4.19.1673 LAPACKE_ssyevx_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyevx_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       float *a, armpl_int_t lda, float vl,
                                       float vu, armpl_int_t il,
                                       armpl_int_t iu, float abstol,
                                       armpl_int_t *m, float *w, float *z,
                                       armpl_int_t ldz, float *work,
                                       armpl_int_t lwork, armpl_int_t *iwork,
                                       armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1674 LAPACKE_ssyevx_work

4.19.1675 LAPACKE_ssygst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssygst(armpl_int_t matrix_layout, armpl_int_t itype,
                           char uplo, armpl_int_t n, float *a,
                           armpl_int_t lda, const float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygst* and *LAPACKE_ssygst*. It also exists with a native Fortran interface as *ssygst*.

4.19.1676 LAPACKE_ssygst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssygst_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char uplo, armpl_int_t n, float *a,
                                armpl_int_t lda, const float *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygst_work* and *LAPACKE_ssygst_work*.

4.19.1677 LAPACKE_ssygv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssygv(armpl_int_t matrix_layout, armpl_int_t itype,
                          char jobz, char uplo, armpl_int_t n, float *a,
                          armpl_int_t lda, float *b, armpl_int_t ldb,
                          float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygv* and *LAPACKE_ssygv*. It also exists with a native Fortran interface as *ssygv*.

4.19.1678 LAPACKE_ssygv_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssygv_2stage(armpl_int_t matrix_layout, armpl_int_t itype,
                                 char jobz, char uplo, armpl_int_t n,
                                 float *a, armpl_int_t lda, float *b,
                                 armpl_int_t ldb, float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygv_2stage* and *LAPACKE_ssygv_2stage*. It also exists with a native Fortran interface as *ssygv_2stage*.

4.19.1679 LAPACKE_ssygv_2stage_work

4.19.1680 LAPACKE_ssygv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssygv_work(armpl_int_t matrix_layout, armpl_int_t itype,
                               char jobz, char uplo, armpl_int_t n, float *a,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                float *w, float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygv_work* and *LAPACKE_ssygv_work*.

4.19.1681 LAPACKE_ssygvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssygvd(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char uplo, armpl_int_t n, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           float *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygvd* and *LAPACKE_ssygvd*. It also exists with a native Fortran interface as *ssygvd*.

4.19.1682 LAPACKE_ssygvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssygvd_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char uplo, armpl_int_t n, float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                float *w, float *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygvd_work* and *LAPACKE_ssygvd_work*.

4.19.1683 LAPACKE_ssygvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssygvx(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char range, char uplo, armpl_int_t n,
                           float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, float vl, float vu,
                           armpl_int_t il, armpl_int_t iu, float abstol,
                           armpl_int_t *m, float *w, float *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygvx* and *LAPACKE_ssygvx*. It also exists with a native Fortran interface as *ssygvx*.

4.19.1684 LAPACKE_ssygvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssygvx_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char range, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *b, armpl_int_t ldb, float vl, float vu,
                                armpl_int_t il, armpl_int_t iu, float abstol,
                                armpl_int_t *m, float *w, float *z,
                                armpl_int_t ldz, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsygvx_work* and *LAPACKE_ssygvx_work*.

4.19.1685 LAPACKE_ssyrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *a,
                           armpl_int_t lda, const float *af, armpl_int_t ldaf,
                           const armpl_int_t *ipiv, const float *b,
                           armpl_int_t ldb, float *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyrfs*, *LAPACKE_dsyrfs*, *LAPACKE_ssyrfs* and *LAPACKE_zsyrfs*. It also exists with a native Fortran interface as *ssyrfs*.

4.19.1686 LAPACKE_ssyrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *a, armpl_int_t lda,
                                const float *af, armpl_int_t ldaf,
                                const armpl_int_t *ipiv, const float *b,
                                armpl_int_t ldb, float *x, armpl_int_t ldx,
                                float *ferr, float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

For this routine in other precisions, please see *LAPACKE_csyrfs_work*, *LAPACKE_dsyrfs_work*, *LAPACKE_ssyrfs_work* and *LAPACKE_zsyrfs_work*.

4.19.1687 LAPACKE_ssyrfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyrfsx(armpl_int_t matrix_layout, char uplo, char equed,
                            armpl_int_t n, armpl_int_t nrhs, const float *a,
                            armpl_int_t lda, const float *af,
                            armpl_int_t ldaf, const armpl_int_t *ipiv,
                            const float *s, const float *b, armpl_int_t ldb,
                            float *x, armpl_int_t ldx, float *rcond,
                            float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1688 LAPACKE_ssyrfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyrfsx_work(armpl_int_t matrix_layout, char uplo,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const float *a, armpl_int_t lda,
                                 const float *af, armpl_int_t ldaf,
                                 const armpl_int_t *ipiv, const float *s,
                                 const float *b, armpl_int_t ldb, float *x,
                                 armpl_int_t ldx, float *rcond, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, float *work,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyrfsx_work*, *LAPACKE_dsyrfsx_work*, *LAPACKE_ssyrfsx_work* and *LAPACKE_zsyrfsx_work*.

4.19.1689 LAPACKE_ssysv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, float *a, armpl_int_t lda,
                          armpl_int_t *ipiv, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv*, *LAPACKE_dsysv*, *LAPACKE_ssysv* and *LAPACKE_zsysv*. It also exists with a native Fortran interface as *ssysv*.

4.19.1690 LAPACKE_ssysv_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysv_aa(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs, float *a,
                             armpl_int_t lda, armpl_int_t *ipiv, float *b,
                             armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_aa*, *LAPACKE_dsysv_aa*, *LAPACKE_ssysv_aa* and *LAPACKE_zsysv_aa*. It also exists with a native Fortran interface as *ssysv_aa*.

4.19.1691 LAPACKE_ssysv_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysv_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs, float *a,
                                    armpl_int_t lda, float *tb,
                                    armpl_int_t ltb, armpl_int_t *ipiv,
                                    armpl_int_t *ipiv2, float *b,
                                    armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_aa_2stage*, *LAPACKE_dsysv_aa_2stage*, *LAPACKE_ssysv_aa_2stage* and *LAPACKE_zsysv_aa_2stage*. It also exists with a native Fortran interface as *ssysv_aa_2stage*.

4.19.1692 LAPACKE_ssysv_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysv_aa_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs, float *a,
                                  armpl_int_t lda, armpl_int_t *ipiv,
                                  float *b, armpl_int_t ldb, float *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_aa_work*, *LAPACKE_dsysv_aa_work*, *LAPACKE_ssysv_aa_work* and *LAPACKE_zsysv_aa_work*.

4.19.1693 LAPACKE_ssysv_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysv_rk(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs, float *a,
                             armpl_int_t lda, float *e, armpl_int_t *ipiv,
                             float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rk*, *LAPACKE_dsysv_rk*, *LAPACKE_ssysv_rk* and *LAPACKE_zsysv_rk*. It also exists with a native Fortran interface as *ssysv_rk*.

4.19.1694 LAPACKE_ssysv_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysv_rk_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs, float *a,
                                  armpl_int_t lda, float *e,
                                  armpl_int_t *ipiv, float *b,
                                  armpl_int_t ldb, float *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rk_work*, *LAPACKE_dsysv_rk_work*, *LAPACKE_ssysv_rk_work* and *LAPACKE_zsysv_rk_work*.

4.19.1695 LAPACKE_ssysv_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysv_rook(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, float *a,
                               armpl_int_t lda, armpl_int_t *ipiv, float *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rook*, *LAPACKE_dsysv_rook*, *LAPACKE_ssysv_rook* and *LAPACKE_zsysv_rook*. It also exists with a native Fortran interface as *ssysv_rook*.

4.19.1696 LAPACKE_ssysv_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysv_rook_work(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs, float *a,
                                    armpl_int_t lda, armpl_int_t *ipiv,
                                    float *b, armpl_int_t ldb, float *work,
                                    armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rook_work*, *LAPACKE_dsysv_rook_work*, *LAPACKE_ssysv_rook_work* and *LAPACKE_zsysv_rook_work*.

4.19.1697 LAPACKE_ssysv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs, float *a,
                               armpl_int_t lda, armpl_int_t *ipiv, float *b,
                               armpl_int_t ldb, float *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_work*, *LAPACKE_dsysv_work*, *LAPACKE_ssysv_work* and *LAPACKE_zsysv_work*.

4.19.1698 LAPACKE_ssysvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *a,
                           armpl_int_t lda, float *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, const float *b, armpl_int_t ldb,
                           float *x, armpl_int_t ldx, float *rcond,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvx*, *LAPACKE_dsysvx*, *LAPACKE_ssysvx* and *LAPACKE_zsysvx*. It also exists with a native Fortran interface as *ssysvx*.

4.19.1699 LAPACKE_ssysvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const float *a, armpl_int_t lda, float *af,
                                armpl_int_t ldaf, armpl_int_t *ipiv,
                                const float *b, armpl_int_t ldb, float *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, float *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvx_work*, *LAPACKE_dsysvx_work*, *LAPACKE_ssysvx_work* and *LAPACKE_zsysvx_work*.

4.19.1700 LAPACKE_ssysvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs, float *a,
                            armpl_int_t lda, float *af, armpl_int_t ldaf,
                            armpl_int_t *ipiv, char *equed, float *s,
                            float *b, armpl_int_t ldb, float *x,
                            armpl_int_t ldx, float *rcond, float *rpvgrw,
                            float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvxx*, *LAPACKE_dsysvxx*, *LAPACKE_ssysvxx* and *LAPACKE_zsysvxx*. It also exists with a native Fortran interface as *ssysvxx*.

4.19.1701 LAPACKE_ssysvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssysvxx_work(armpl_int_t matrix_layout, char fact,
                                 char uplo, armpl_int_t n, armpl_int_t nrhs,
                                 float *a, armpl_int_t lda, float *af,
                                 armpl_int_t ldaf, armpl_int_t *ipiv,
                                 char *equed, float *s, float *b,
                                 armpl_int_t ldb, float *x, armpl_int_t ldx,
                                 float *rcond, float *rpvgrw, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, float *work,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvxx_work*, *LAPACKE_dsysvxx_work*, *LAPACKE_ssysvxx_work* and *LAPACKE_zsysvxx_work*.

4.19.1702 LAPACKE_ssyswapr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyswapr(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, float *a, armpl_int_t lda,
                             armpl_int_t i1, armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyswapr*, *LAPACKE_dsyswapr*, *LAPACKE_ssyswapr* and *LAPACKE_zsyswapr*. It also exists with a native Fortran interface as *ssyswapr*.

4.19.1703 LAPACKE_ssyswapr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssyswapr_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, float *a, armpl_int_t lda,
                                  armpl_int_t i1, armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyswapr_work*, *LAPACKE_dsyswapr_work*, *LAPACKE_ssyswapr_work* and *LAPACKE_zsyswapr_work*.

4.19.1704 LAPACKE_ssytrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrd(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *a, armpl_int_t lda, float *d,
                           float *e, float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsytrd* and *LAPACKE_ssytrd*. It also exists with a native Fortran interface as *ssytrd*.

4.19.1705 LAPACKE_ssytrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrd_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *d, float *e, float *tau, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_dsytrd_work* and *LAPACKE_ssytrd_work*.

4.19.1706 LAPACKE_ssytrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf*, *LAPACKE_dsytrf*, *LAPACKE_ssytrf* and *LAPACKE_zsytrf*. It also exists with a native Fortran interface as *ssytrf*.

4.19.1707 LAPACKE_ssytrf_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrf_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, float *a, armpl_int_t lda,
                              armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa*, *LAPACKE_dsytrf_aa*, *LAPACKE_ssytrf_aa* and *LAPACKE_zsytrf_aa*. It also exists with a native Fortran interface as *ssytrf_aa*.

4.19.1708 LAPACKE_ssytrf_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrf_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, float *a, armpl_int_t lda,
                                     float *tb, armpl_int_t ltb,
                                     armpl_int_t *ipiv, armpl_int_t *ipiv2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa_2stage*, *LAPACKE_dsytrf_aa_2stage*, *LAPACKE_ssytrf_aa_2stage* and *LAPACKE_zsytrf_aa_2stage*. It also exists with a native Fortran interface as *ssytrf_aa_2stage*.

4.19.1709 LAPACKE_ssytrf_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrf_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, float *a, armpl_int_t lda,
                                   armpl_int_t *ipiv, float *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa_work*, *LAPACKE_dsytrf_aa_work*, *LAPACKE_ssytrf_aa_work* and *LAPACKE_zsytrf_aa_work*.

4.19.1710 LAPACKE_ssytrf_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrf_rk(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, float *a, armpl_int_t lda,
                              float *e, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rk*, *LAPACKE_dsytrf_rk*, *LAPACKE_ssytrf_rk* and *LAPACKE_zsytrf_rk*. It also exists with a native Fortran interface as *ssytrf_rk*.

4.19.1711 LAPACKE_ssytrf_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrf_rk_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, float *a, armpl_int_t lda,
                                   float *e, armpl_int_t *ipiv, float *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rk_work*, *LAPACKE_dsytrf_rk_work*, *LAPACKE_ssytrf_rk_work* and *LAPACKE_zsytrf_rk_work*.

4.19.1712 LAPACKE_ssytrf_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrf_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rook*, *LAPACKE_dsytrf_rook*, *LAPACKE_ssytrf_rook* and *LAPACKE_zsytrf_rook*. It also exists with a native Fortran interface as *ssytrf_rook*.

4.19.1713 LAPACKE_ssytrf_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrf_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, float *a, armpl_int_t lda,
                                     armpl_int_t *ipiv, float *work,
                                     armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rook_work*, *LAPACKE_dsytrf_rook_work*, *LAPACKE_ssytrf_rook_work* and *LAPACKE_zsytrf_rook_work*.

4.19.1714 LAPACKE_ssytrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                armpl_int_t *ipiv, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_work*, *LAPACKE_dsytrf_work*, *LAPACKE_ssytrf_work* and *LAPACKE_zsytrf_work*.

4.19.1715 LAPACKE_ssytri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri*, *LAPACKE_dsytri*, *LAPACKE_ssytri* and *LAPACKE_zsytri*. It also exists with a native Fortran interface as *ssytri*.

4.19.1716 LAPACKE_ssytri2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytri2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, float *a, armpl_int_t lda,
                            const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2*, *LAPACKE_dsytri2*, *LAPACKE_ssytri2* and *LAPACKE_zsytri2*. It also exists with a native Fortran interface as *ssytri2*.

4.19.1717 LAPACKE_ssytri2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytri2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, float *a, armpl_int_t lda,
                                 const armpl_int_t *ipiv, float *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2_work*, *LAPACKE_dsytri2_work*, *LAPACKE_ssytri2_work* and *LAPACKE_zsytri2_work*.

4.19.1718 LAPACKE_ssytri2x

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytri2x(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, float *a, armpl_int_t lda,
                             const armpl_int_t *ipiv, armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2x*, *LAPACKE_dsytri2x*, *LAPACKE_ssytri2x* and *LAPACKE_zsytri2x*. It also exists with a native Fortran interface as *ssytri2x*.

4.19.1719 LAPACKE_ssytri2x_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytri2x_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, float *a, armpl_int_t lda,
                                  const armpl_int_t *ipiv, float *work,
                                  armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2x_work*, *LAPACKE_dsytri2x_work*, *LAPACKE_ssytri2x_work* and *LAPACKE_zsytri2x_work*.

4.19.1720 LAPACKE_ssytri_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytri_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, float *a, armpl_int_t lda,
                             const float *e, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri_3*, *LAPACKE_dsytri_3*, *LAPACKE_ssytri_3* and *LAPACKE_zsytri_3*. It also exists with a native Fortran interface as *ssytri_3*.

4.19.1721 LAPACKE_ssytri_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytri_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, float *a, armpl_int_t lda,
                                  const float *e, const armpl_int_t *ipiv,
                                  float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri_3_work*, *LAPACKE_dsytri_3_work*, *LAPACKE_ssytri_3_work* and *LAPACKE_zsytri_3_work*.

4.19.1722 LAPACKE_ssytri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri_work*, *LAPACKE_dsytri_work*, *LAPACKE_ssytri_work* and *LAPACKE_zsytri_work*.

4.19.1723 LAPACKE_ssytrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const float *a,
                           armpl_int_t lda, const armpl_int_t *ipiv, float *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs*, *LAPACKE_dsytrs*, *LAPACKE_ssytrs* and *LAPACKE_zsytrs*. It also exists with a native Fortran interface as *ssytrs*.

4.19.1724 LAPACKE_ssytrs2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_int_t nrhs, const float *a,
                            armpl_int_t lda, const armpl_int_t *ipiv,
                            float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs2*, *LAPACKE_dsytrs2*, *LAPACKE_ssytrs2* and *LAPACKE_zsytrs2*. It also exists with a native Fortran interface as *ssytrs2*.

4.19.1725 LAPACKE_ssytrs2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_int_t nrhs,
                                 const float *a, armpl_int_t lda,
                                 const armpl_int_t *ipiv, float *b,
                                 armpl_int_t ldb, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs2_work*, *LAPACKE_dsytrs2_work*, *LAPACKE_ssytrs2_work* and *LAPACKE_zsytrs2_work*.

4.19.1726 LAPACKE_ssytrs_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs, const float *a,
                             armpl_int_t lda, const float *e,
                             const armpl_int_t *ipiv, float *b,
                             armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_3*, *LAPACKE_dsytrs_3*, *LAPACKE_ssytrs_3* and *LAPACKE_zsytrs_3*. It also exists with a native Fortran interface as *ssytrs_3*.

4.19.1727 LAPACKE_ssytrs_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  const float *a, armpl_int_t lda,
                                  const float *e, const armpl_int_t *ipiv,
                                  float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_3_work*, *LAPACKE_dsytrs_3_work*, *LAPACKE_ssytrs_3_work* and *LAPACKE_zsytrs_3_work*.

4.19.1728 LAPACKE_ssytrs_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_int_t nrhs, const float *a,
                              armpl_int_t lda, const armpl_int_t *ipiv,
                              float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa*, *LAPACKE_dsytrs_aa*, *LAPACKE_ssytrs_aa* and *LAPACKE_zsytrs_aa*. It also exists with a native Fortran interface as *ssytrs_aa*.

4.19.1729 LAPACKE_ssytrs_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     float *a, armpl_int_t lda, float *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2, float *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa_2stage*, *LAPACKE_dsytrs_aa_2stage*, *LAPACKE_ssytrs_aa_2stage* and *LAPACKE_zsytrs_aa_2stage*. It also exists with a native Fortran interface as *ssytrs_aa_2stage*.

4.19.1730 LAPACKE_ssytrs_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_int_t nrhs,
                                   const float *a, armpl_int_t lda,
                                   const armpl_int_t *ipiv, float *b,
                                   armpl_int_t ldb, float *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa_work*, *LAPACKE_dsytrs_aa_work*, *LAPACKE_ssytrs_aa_work* and *LAPACKE_zsytrs_aa_work*.

4.19.1731 LAPACKE_ssytrs_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, float *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1732 LAPACKE_ssytrs_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     const float *a, armpl_int_t lda,
                                     const armpl_int_t *ipiv, float *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_rook_work*, *LAPACKE_dsytrs_rook_work*, *LAPACKE_ssytrs_rook_work* and *LAPACKE_zsytrs_rook_work*.

4.19.1733 LAPACKE_ssytrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ssytrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const float *a, armpl_int_t lda,
                                const armpl_int_t *ipiv, float *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_work*, *LAPACKE_dsytrs_work*, *LAPACKE_ssytrs_work* and *LAPACKE_zsytrs_work*.

4.19.1734 LAPACKE_stbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stbcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           const float *ab, armpl_int_t ldab, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbcon*, *LAPACKE_dtbcon*, *LAPACKE_stbcon* and *LAPACKE_ztbcon*. It also exists with a native Fortran interface as *stbcon*.

4.19.1735 LAPACKE_stbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stbcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                armpl_int_t kd, const float *ab,
                                armpl_int_t ldab, float *rcond, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbcon_work*, *LAPACKE_dtbcon_work*, *LAPACKE_stbcon_work* and *LAPACKE_ztbcon_work*.

4.19.1736 LAPACKE_stbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stbrfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           armpl_int_t nrhs, const float *ab,
                           armpl_int_t ldab, const float *b, armpl_int_t ldb,
                           const float *x, armpl_int_t ldx, float *ferr,
                           float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbrfs*, *LAPACKE_dtbrfs*, *LAPACKE_stbrfs* and *LAPACKE_ztbrfs*. It also exists with a native Fortran interface as *stbrfs*.

4.19.1737 LAPACKE_stbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stbrfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t kd, armpl_int_t nrhs,
                                const float *ab, armpl_int_t ldab,
                                const float *b, armpl_int_t ldb,
                                const float *x, armpl_int_t ldx, float *ferr,
                                float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbrfs_work*, *LAPACKE_dtbrfs_work*, *LAPACKE_stbrfs_work* and *LAPACKE_ztbrfs_work*.

4.19.1738 LAPACKE_stbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stbtrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           armpl_int_t nrhs, const float *ab,
                           armpl_int_t ldab, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbtrs*, *LAPACKE_dtbtrs*, *LAPACKE_stbtrs* and *LAPACKE_ztbtrs*. It also exists with a native Fortran interface as *stbtrs*.

4.19.1739 LAPACKE_stbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stbtrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t kd, armpl_int_t nrhs,
                                const float *ab, armpl_int_t ldab, float *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbtrs_work*, *LAPACKE_dtbtrs_work*, *LAPACKE_stbtrs_work* and *LAPACKE_ztbtrs_work*.

4.19.1740 LAPACKE_stfsm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stfsm(armpl_int_t matrix_layout, char transr, char side,
                          char uplo, char trans, char diag, armpl_int_t m,
                          armpl_int_t n, float alpha, const float *a,
                          float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfsm*, *LAPACKE_dtfsm*, *LAPACKE_stfsm* and *LAPACKE_ztfsm*. It also exists with a native Fortran interface as *stfsm*.

4.19.1741 LAPACKE_stfsm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stfsm_work(armpl_int_t matrix_layout, char transr,
                               char side, char uplo, char trans, char diag,
                               armpl_int_t m, armpl_int_t n, float alpha,
                               const float *a, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfsm_work*, *LAPACKE_dtfsm_work*, *LAPACKE_stfsm_work* and *LAPACKE_ztfsm_work*.

4.19.1742 LAPACKE_stftri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stftri(armpl_int_t matrix_layout, char transr, char uplo,
                           char diag, armpl_int_t n, float *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctftri*, *LAPACKE_dtftri*, *LAPACKE_stftri* and *LAPACKE_ztftri*. It also exists with a native Fortran interface as *stftri*.

4.19.1743 LAPACKE_stftri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stftri_work(armpl_int_t matrix_layout, char transr,
                                char uplo, char diag, armpl_int_t n,
                                float *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctftri_work*, *LAPACKE_dtftri_work*, *LAPACKE_stftri_work* and *LAPACKE_ztftri_work*.

4.19.1744 LAPACKE_stfttp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stfttp(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const float *arf, float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttp*, *LAPACKE_dtfttp*, *LAPACKE_stfttp* and *LAPACKE_ztfttp*. It also exists with a native Fortran interface as *stfttp*.

4.19.1745 LAPACKE_stfttp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stfttp_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, const float *arf,
                                float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttp_work*, *LAPACKE_dtfttp_work*, *LAPACKE_stfttp_work* and *LAPACKE_ztfttp_work*.

4.19.1746 LAPACKE_stfttr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stfttr(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const float *arf, float *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttr*, *LAPACKE_dtfttr*, *LAPACKE_stfttr* and *LAPACKE_ztfttr*. It also exists with a native Fortran interface as *stfttr*.

4.19.1747 LAPACKE_stfttr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stfttr_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, const float *arf,
                                float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1748 LAPACKE_stgevc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgevc(armpl_int_t matrix_layout, char side, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const float *s, armpl_int_t lds, const float *p,
                           armpl_int_t ldp, float *vl, armpl_int_t ldvl,
                           float *vr, armpl_int_t ldvr, armpl_int_t mm,
                           armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgevc*, *LAPACKE_dtgevc*, *LAPACKE_stgevc* and *LAPACKE_ztgevc*. It also exists with a native Fortran interface as *stgevc*.

4.19.1749 LAPACKE_stgevc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgevc_work(armpl_int_t matrix_layout, char side,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, const float *s,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t lds, const float *p,
                                armpl_int_t ldp, float *vl, armpl_int_t ldvl,
                                float *vr, armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgevc_work*, *LAPACKE_dtgevc_work*, *LAPACKE_stgevc_work* and *LAPACKE_ztgevc_work*.

4.19.1750 LAPACKE_stgexc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgexc(armpl_int_t matrix_layout, armpl_int_t wantq,
                           armpl_int_t wantz, armpl_int_t n, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           float *q, armpl_int_t ldq, float *z,
                           armpl_int_t ldz, armpl_int_t *ifst,
                           armpl_int_t *ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgexc*, *LAPACKE_dtgexc*, *LAPACKE_stgexc* and *LAPACKE_ztgexc*. It also exists with a native Fortran interface as *stgexc*.

4.19.1751 LAPACKE_stgexc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgexc_work(armpl_int_t matrix_layout, armpl_int_t wantq,
                                armpl_int_t wantz, armpl_int_t n, float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb,
                                float *q, armpl_int_t ldq, float *z,
                                armpl_int_t ldz, armpl_int_t *ifst,
                                armpl_int_t *ilst, float *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgexc_work*, *LAPACKE_dtgexc_work*, *LAPACKE_stgexc_work* and *LAPACKE_ztgexc_work*.

4.19.1752 LAPACKE_stgsen

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgsen(armpl_int_t matrix_layout, armpl_int_t ijob,
                           armpl_int_t wantq, armpl_int_t wantz,
                           const armpl_int_t *select, armpl_int_t n, float *a,
                           armpl_int_t lda, float *b, armpl_int_t ldb,
                           float *alphar, float *alphai, float *beta,
                           float *q, armpl_int_t ldq, float *z,
                           armpl_int_t ldz, armpl_int_t *m, float *pl,
                           float *pr, float *dif);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsen*, *LAPACKE_dtgsen*, *LAPACKE_stgsen* and *LAPACKE_ztgsen*. It also exists with a native Fortran interface as *stgsen*.

4.19.1753 LAPACKE_stgsen_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgsen_work(armpl_int_t matrix_layout, armpl_int_t ijob,
                                armpl_int_t wantq, armpl_int_t wantz,
                                const armpl_int_t *select, armpl_int_t n,
                                float *a, armpl_int_t lda, float *b,
                                armpl_int_t ldb, float *alphar, float *alphai,
                                float *beta, float *q, armpl_int_t ldq,
                                float *z, armpl_int_t ldz, armpl_int_t *m,
                                float *pl, float *pr, float *dif, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsen_work*, *LAPACKE_dtgsen_work*, *LAPACKE_stgsen_work* and *LAPACKE_ztgsen_work*.

4.19.1754 LAPACKE_stgsja

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgsja(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t p,
                           armpl_int_t n, armpl_int_t k, armpl_int_t l,
                           float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, float tola, float tolb,
                           float *alpha, float *beta, float *u,
                           armpl_int_t ldu, float *v, armpl_int_t ldv,
                           float *q, armpl_int_t ldq, armpl_int_t *ncycle);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1755 LAPACKE_stgsja_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgsja_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n, armpl_int_t k,
                                armpl_int_t l, float *a, armpl_int_t lda,
                                float *b, armpl_int_t ldb, float tola,
                                float tolb, float *alpha, float *beta,
                                float *u, armpl_int_t ldu, float *v,
                                armpl_int_t ldv, float *q, armpl_int_t ldq,
                                float *work, armpl_int_t *ncycle);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1756 LAPACKE_stgsna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgsna(armpl_int_t matrix_layout, char job, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const float *a, armpl_int_t lda, const float *b,
                           armpl_int_t ldb, const float *vl, armpl_int_t ldvl,
```

(continues on next page)

(continued from previous page)

```
                                const float *vr, armpl_int_t ldvr, float *s,
                                float *dif, armpl_int_t mm, armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsna*, *LAPACKE_dtgsna*, *LAPACKE_stgsna* and *LAPACKE_ztgsna*. It also exists with a native Fortran interface as *stgsna*.

4.19.1757 LAPACKE_stgsna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgsna_work(armpl_int_t matrix_layout, char job,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda, const float *b,
                                armpl_int_t ldb, const float *vl,
                                armpl_int_t ldvl, const float *vr,
                                armpl_int_t ldvr, float *s, float *dif,
                                armpl_int_t mm, armpl_int_t *m, float *work,
                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsna_work*, *LAPACKE_dtgsna_work*, *LAPACKE_stgsna_work* and *LAPACKE_ztgsna_work*.

4.19.1758 LAPACKE_stgsyl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgsyl(armpl_int_t matrix_layout, char trans,
                           armpl_int_t ijob, armpl_int_t m, armpl_int_t n,
                           const float *a, armpl_int_t lda, const float *b,
                           armpl_int_t ldb, float *c, armpl_int_t ldc,
                           const float *d, armpl_int_t ldd, const float *e,
                           armpl_int_t lde, float *f, armpl_int_t ldf,
                           float *scale, float *dif);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsyl*, *LAPACKE_dtgsyl*, *LAPACKE_stgsyl* and *LAPACKE_ztgsyl*. It also exists with a native Fortran interface as *stgsyl*.

4.19.1759 LAPACKE_stgsyl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stgsyl_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t ijob, armpl_int_t m,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda, const float *b,
                                armpl_int_t ldb, float *c, armpl_int_t ldc,
                                const float *d, armpl_int_t ldd,
                                const float *e, armpl_int_t lde, float *f,
                                armpl_int_t ldf, float *scale, float *dif,
                                float *work, armpl_int_t lwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsyl_work*, *LAPACKE_dtgsyl_work*, *LAPACKE_stgsyl_work* and *LAPACKE_ztgsyl_work*.

4.19.1760 LAPACKE_stpcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n, const float *ap,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpcon*, *LAPACKE_dtpcon*, *LAPACKE_stpcon* and *LAPACKE_ztpcon*. It also exists with a native Fortran interface as *stpcon*.

4.19.1761 LAPACKE_stpcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                const float *ap, float *rcond, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpcon_work*, *LAPACKE_dtpcon_work*, *LAPACKE_stpcon_work* and *LAPACKE_ztpcon_work*.

4.19.1762 LAPACKE_stpmqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpmqrt(armpl_int_t matrix_layout, char side, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t k,
                            armpl_int_t l, armpl_int_t nb, const float *v,
                            armpl_int_t ldv, const float *t, armpl_int_t ldt,
                            float *a, armpl_int_t lda, float *b,
                            armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpmqrt*, *LAPACKE_dtpmqrt*, *LAPACKE_stpmqrt* and *LAPACKE_ztpmqrt*. It also exists with a native Fortran interface as *stpmqrt*.

4.19.1763 LAPACKE_stpmqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpmqrt_work(armpl_int_t matrix_layout, char side,
                                 char trans, armpl_int_t m, armpl_int_t n,
                                 armpl_int_t k, armpl_int_t l, armpl_int_t nb,
                                 const float *v, armpl_int_t ldv,
                                 const float *t, armpl_int_t ldt, float *a,
                                 armpl_int_t lda, float *b, armpl_int_t ldb,
                                 float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1764 LAPACKE_stpqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpqrt(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t l, armpl_int_t nb,
                           float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb, float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt*, *LAPACKE_dtpqrt*, *LAPACKE_stpqrt* and *LAPACKE_ztpqrt*. It also exists with a native Fortran interface as *stpqrt*.

4.19.1765 LAPACKE_stpqrt2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpqrt2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_int_t l, float *a,
                            armpl_int_t lda, float *b, armpl_int_t ldb,
                            float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt2*, *LAPACKE_dtpqrt2*, *LAPACKE_stpqrt2* and *LAPACKE_ztpqrt2*. It also exists with a native Fortran interface as *stpqrt2*.

4.19.1766 LAPACKE_stpqrt2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpqrt2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t l, float *a,
                                 armpl_int_t lda, float *b, armpl_int_t ldb,
                                 float *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt2_work*, *LAPACKE_dtpqrt2_work*, *LAPACKE_stpqrt2_work* and *LAPACKE_ztpqrt2_work*.

4.19.1767 LAPACKE_stpqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpqrt_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t l, armpl_int_t nb,
                                float *a, armpl_int_t lda, float *b,
                                armpl_int_t ldb, float *t, armpl_int_t ldt,
                                float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt_work*, *LAPACKE_dtpqrt_work*, *LAPACKE_stpqrt_work* and *LAPACKE_ztpqrt_work*.

4.19.1768 LAPACKE_stprfb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stprfb(armpl_int_t matrix_layout, char side, char trans,
                           char direct, char storev, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, armpl_int_t l,
                           const float *v, armpl_int_t ldv, const float *t,
                           armpl_int_t ldt, float *a, armpl_int_t lda,
                           float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfb*, *LAPACKE_dtprfb*, *LAPACKE_stprfb* and *LAPACKE_ztprfb*. It also exists with a native Fortran interface as *stprfb*.

4.19.1769 LAPACKE_stprfb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stprfb_work(armpl_int_t matrix_layout, char side,
                                char trans, char direct, char storev,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t l, const float *v,
                                armpl_int_t ldv, const float *t,
                                armpl_int_t ldt, float *a, armpl_int_t lda,
                                float *b, armpl_int_t ldb, float *work,
                                armpl_int_t ldwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfb_work*, *LAPACKE_dtprfb_work*, *LAPACKE_stprfb_work* and *LAPACKE_ztprfb_work*.

4.19.1770 LAPACKE_stprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stprfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const float *ap, const float *b, armpl_int_t ldb,
                           const float *x, armpl_int_t ldx, float *ferr,
                           float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfs*, *LAPACKE_dtprfs*, *LAPACKE_stprfs* and *LAPACKE_ztprfs*. It also exists with a native Fortran interface as *stprfs*.

4.19.1771 LAPACKE_stprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stprfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs, const float *ap,
                                const float *b, armpl_int_t ldb,
                                const float *x, armpl_int_t ldx, float *ferr,
                                float *berr, float *work,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfs_work*, *LAPACKE_dtprfs_work*, *LAPACKE_stprfs_work* and *LAPACKE_ztprfs_work*.

4.19.1772 LAPACKE_stptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stptri(armpl_int_t matrix_layout, char uplo, char diag,
                           armpl_int_t n, float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptri*, *LAPACKE_dtptri*, *LAPACKE_stptri* and *LAPACKE_ztptri*. It also exists with a native Fortran interface as *stptri*.

4.19.1773 LAPACKE_stptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stptri_work(armpl_int_t matrix_layout, char uplo,
                                char diag, armpl_int_t n, float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptri_work*, *LAPACKE_dtptri_work*, *LAPACKE_stptri_work* and *LAPACKE_ztptri_work*.

4.19.1774 LAPACKE_stptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stptrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const float *ap, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptrs*, *LAPACKE_dtptrs*, *LAPACKE_stptrs* and *LAPACKE_ztptrs*. It also exists with a native Fortran interface as *stptrs*.

4.19.1775 LAPACKE_stptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stptrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs, const float *ap, float *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptrs_work*, *LAPACKE_dtptrs_work*, *LAPACKE_stptrs_work* and *LAPACKE_ztptrs_work*.

4.19.1776 LAPACKE_stpttf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpttf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const float *ap, float *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttf*, *LAPACKE_dtpttf*, *LAPACKE_stpttf* and *LAPACKE_ztpttf*. It also exists with a native Fortran interface as *stpttf*.

4.19.1777 LAPACKE_stpttf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpttf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, const float *ap,
                                float *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttf_work*, *LAPACKE_dtpttf_work*, *LAPACKE_stpttf_work* and *LAPACKE_ztpttf_work*.

4.19.1778 LAPACKE_stpttr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpttr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const float *ap, float *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttr*, *LAPACKE_dtpttr*, *LAPACKE_stpttr* and *LAPACKE_ztpttr*. It also exists with a native Fortran interface as *stpttr*.

4.19.1779 LAPACKE_stpttr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stpttr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const float *ap, float *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttr_work*, *LAPACKE_dtpttr_work*, *LAPACKE_stpttr_work* and *LAPACKE_ztpttr_work*.

4.19.1780 LAPACKE_strcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n, const float *a,
                           armpl_int_t lda, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrcon*, *LAPACKE_dtrcon*, *LAPACKE_strcon* and *LAPACKE_ztrcon*. It also exists with a native Fortran interface as *strcon*.

4.19.1781 LAPACKE_strcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                const float *a, armpl_int_t lda, float *rcond,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrcon_work*, *LAPACKE_dtrcon_work*, *LAPACKE_strcon_work* and *LAPACKE_ztrcon_work*.

4.19.1782 LAPACKE_strevc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strevc(armpl_int_t matrix_layout, char side, char howmny,
                           armpl_int_t *select, armpl_int_t n, const float *t,
                           armpl_int_t ldt, float *vl, armpl_int_t ldvl,
                           float *vr, armpl_int_t ldvr, armpl_int_t mm,
                           armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrevc*, *LAPACKE_dtrevc*, *LAPACKE_strevc* and *LAPACKE_ztrevc*. It also exists with a native Fortran interface as *strevc*.

4.19.1783 LAPACKE_strevc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strevc_work(armpl_int_t matrix_layout, char side,
                                char howmny, armpl_int_t *select,
                                armpl_int_t n, const float *t,
                                armpl_int_t ldt, float *vl, armpl_int_t ldvl,
                                float *vr, armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrevc_work*, *LAPACKE_dtrevc_work*, *LAPACKE_strevc_work* and *LAPACKE_ztrevc_work*.

4.19.1784 LAPACKE_strexc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strexc(armpl_int_t matrix_layout, char compq,
                           armpl_int_t n, float *t, armpl_int_t ldt, float *q,
                           armpl_int_t ldq, armpl_int_t *ifst,
                           armpl_int_t *ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrexc*, *LAPACKE_dtrexc*, *LAPACKE_strexc* and *LAPACKE_ztrexc*. It also exists with a native Fortran interface as *strexc*.

4.19.1785 LAPACKE_strexc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strexc_work(armpl_int_t matrix_layout, char compq,
                                armpl_int_t n, float *t, armpl_int_t ldt,
                                float *q, armpl_int_t ldq, armpl_int_t *ifst,
                                armpl_int_t *ilst, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrexc_work*, *LAPACKE_dtrexc_work*, *LAPACKE_strexc_work* and *LAPACKE_ztrexc_work*.

4.19.1786 LAPACKE_strrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strrfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const float *a, armpl_int_t lda, const float *b,
                           armpl_int_t ldb, const float *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrrfs*, *LAPACKE_dtrrfs*, *LAPACKE_strrfs* and *LAPACKE_ztrrfs*. It also exists with a native Fortran interface as *strrfs*.

4.19.1787 LAPACKE_strrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strrfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs, const float *a,
                                armpl_int_t lda, const float *b,
                                armpl_int_t ldb, const float *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                float *work, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrrfs_work*, *LAPACKE_dtrrfs_work*, *LAPACKE_strrfs_work* and *LAPACKE_ztrrfs_work*.

4.19.1788 LAPACKE_strsen

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strsen(armpl_int_t matrix_layout, char job, char compq,
                           const armpl_int_t *select, armpl_int_t n, float *t,
                           armpl_int_t ldt, float *q, armpl_int_t ldq,
                           float *wr, float *wi, armpl_int_t *m, float *s,
                           float *sep);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsen*, *LAPACKE_dtrsen*, *LAPACKE_strsen* and *LAPACKE_ztrsen*. It also exists with a native Fortran interface as *strsen*.

4.19.1789 LAPACKE_strsen_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strsen_work(armpl_int_t matrix_layout, char job,
                                char compq, const armpl_int_t *select,
                                armpl_int_t n, float *t, armpl_int_t ldt,
                                float *q, armpl_int_t ldq, float *wr,
                                float *wi, armpl_int_t *m, float *s,
                                float *sep, float *work, armpl_int_t lwork,
                                armpl_int_t *iwork, armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsen_work*, *LAPACKE_dtrsen_work*, *LAPACKE_strsen_work* and *LAPACKE_ztrsen_work*.

4.19.1790 LAPACKE_strsna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strsna(armpl_int_t matrix_layout, char job, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const float *t, armpl_int_t ldt, const float *vl,
                           armpl_int_t ldvl, const float *vr,
                           armpl_int_t ldvr, float *s, float *sep,
                           armpl_int_t mm, armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsna*, *LAPACKE_dtrsna*, *LAPACKE_strsna* and *LAPACKE_ztrsna*. It also exists with a native Fortran interface as *strsna*.

4.19.1791 LAPACKE_strsna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strsna_work(armpl_int_t matrix_layout, char job,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, const float *t,
                                armpl_int_t ldt, const float *vl,
                                armpl_int_t ldvl, const float *vr,
                                armpl_int_t ldvr, float *s, float *sep,
                                armpl_int_t mm, armpl_int_t *m, float *work,
                                armpl_int_t ldwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsna_work*, *LAPACKE_dtrsna_work*, *LAPACKE_strsna_work* and *LAPACKE_ztrsna_work*.

4.19.1792 LAPACKE_strsyl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strsyl(armpl_int_t matrix_layout, char trana, char tranb,
                           armpl_int_t isgn, armpl_int_t m, armpl_int_t n,
                           const float *a, armpl_int_t lda, const float *b,
                           armpl_int_t ldb, float *c, armpl_int_t ldc,
                           float *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsyl*, *LAPACKE_dtrsyl*, *LAPACKE_strsyl* and *LAPACKE_ztrsyl*. It also exists with a native Fortran interface as *strsyl*.

4.19.1793 LAPACKE_strsyl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strsyl_work(armpl_int_t matrix_layout, char trana,
                                char tranb, armpl_int_t isgn, armpl_int_t m,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda, const float *b,
                                armpl_int_t ldb, float *c, armpl_int_t ldc,
                                float *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsyl_work*, *LAPACKE_dtrsyl_work*, *LAPACKE_strsyl_work* and *LAPACKE_ztrsyl_work*.

4.19.1794 LAPACKE_strtri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strtri(armpl_int_t matrix_layout, char uplo, char diag,
                           armpl_int_t n, float *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtri*, *LAPACKE_dtrtri*, *LAPACKE_strtri* and *LAPACKE_ztrtri*. It also exists with a native Fortran interface as *strtri*.

4.19.1795 LAPACKE_strtri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strtri_work(armpl_int_t matrix_layout, char uplo,
                                char diag, armpl_int_t n, float *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtri_work*, *LAPACKE_dtrtri_work*, *LAPACKE_strtri_work* and *LAPACKE_ztrtri_work*.

4.19.1796 LAPACKE_strtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strtrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const float *a, armpl_int_t lda, float *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtrs*, *LAPACKE_dtrtrs*, *LAPACKE_strtrs* and *LAPACKE_ztrtrs*. It also exists with a native Fortran interface as *strtrs*.

4.19.1797 LAPACKE_strtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strtrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs, const float *a,
                                armpl_int_t lda, float *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtrs_work*, *LAPACKE_dtrtrs_work*, *LAPACKE_strtrs_work* and *LAPACKE_ztrtrs_work*.

4.19.1798 LAPACKE_strttf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strttf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const float *a, armpl_int_t lda,
                           float *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttf*, *LAPACKE_dtrttf*, *LAPACKE_strttf* and *LAPACKE_ztrttf*. It also exists with a native Fortran interface as *strttf*.

4.19.1799 LAPACKE_strttf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strttf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, const float *a,
                                armpl_int_t lda, float *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttf_work*, *LAPACKE_dtrttf_work*, *LAPACKE_strttf_work* and *LAPACKE_ztrttf_work*.

4.19.1800 LAPACKE_strttp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strttp(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const float *a, armpl_int_t lda,
                           float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttp*, *LAPACKE_dtrttp*, *LAPACKE_strttp* and *LAPACKE_ztrttp*. It also exists with a native Fortran interface as *strttp*.

4.19.1801 LAPACKE_strttp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_strttp_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const float *a,
                                armpl_int_t lda, float *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttp_work*, *LAPACKE_dtrttp_work*, *LAPACKE_strttp_work* and *LAPACKE_ztrttp_work*.

4.19.1802 LAPACKE_stzrzf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stzrzf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, float *a, armpl_int_t lda,
                           float *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctzrzf*, *LAPACKE_dtzrzf*, *LAPACKE_stzrzf* and *LAPACKE_ztzrzf*. It also exists with a native Fortran interface as *stzrzf*.

4.19.1803 LAPACKE_stzrzf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_stzrzf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, float *a, armpl_int_t lda,
                                float *tau, float *work, armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctzrzf_work*, *LAPACKE_dtzrzf_work*, *LAPACKE_stzrzf_work* and *LAPACKE_ztzrzf_work*.

4.19.1804 LAPACKE_zbbcsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zbbcsd(armpl_int_t matrix_layout, char jobu1, char jobu2,
                           char jobv1t, char jobv2t, char trans,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           double *theta, double *phi,
                           armpl_doublecomplex_t *u1, armpl_int_t ldu1,
                           armpl_doublecomplex_t *u2, armpl_int_t ldu2,
```

```
                                armpl_doublecomplex_t *v1t, armpl_int_t ldv1t,
                                armpl_doublecomplex_t *v2t, armpl_int_t ldv2t,
                                double *b11d, double *b11e, double *b12d,
                                double *b12e, double *b21d, double *b21e,
                                double *b22d, double *b22e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1807 LAPACKE_zbdsqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zbdsqr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t ncvt,
                                armpl_int_t nru, armpl_int_t ncc, double *d,
                                double *e, armpl_doublecomplex_t *vt,
                                armpl_int_t ldvt, armpl_doublecomplex_t *u,
                                armpl_int_t ldu, armpl_doublecomplex_t *c,
                                armpl_int_t ldc, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1808 LAPACKE_zcgesv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zcgesv(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t nrhs, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *ipiv,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           armpl_int_t *iter);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1814 LAPACKE_zgbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbcon(armpl_int_t matrix_layout, char norm,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           const armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           const armpl_int_t *ipiv, double anorm,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbcon*, *LAPACKE_dgbcon*, *LAPACKE_sgbcon* and *LAPACKE_zgbcon*. It also exists with a native Fortran interface as *zgbcon*.

4.19.1815 LAPACKE_zgbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbcon_work(armpl_int_t matrix_layout, char norm,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, const armpl_int_t *ipiv,
                                double anorm, double *rcond,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1816 LAPACKE_zgbequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbequ(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           const armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           double *r, double *c, double *rowcnd,
                           double *colcnd, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequ*, *LAPACKE_dgbequ*, *LAPACKE_sgbequ* and *LAPACKE_zgbequ*. It also exists with a native Fortran interface as *zgbequ*.

4.19.1817 LAPACKE_zgbequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbequ_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, double *r, double *c,
                                double *rowcnd, double *colcnd,
                                double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1818 LAPACKE_zgbequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbequb(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            const armpl_doublecomplex_t *ab, armpl_int_t ldab,
                            double *r, double *c, double *rowcnd,
                            double *colcnd, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequb*, *LAPACKE_dgbequb*, *LAPACKE_sgbequb* and *LAPACKE_zgbequb*. It also exists with a native Fortran interface as *zgbequb*.

4.19.1819 LAPACKE_zgbequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbequb_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku,
                                 const armpl_doublecomplex_t *ab,
                                 armpl_int_t ldab, double *r, double *c,
                                 double *rowcnd, double *colcnd,
                                 double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequb_work*, *LAPACKE_dgbequb_work*, *LAPACKE_sgbequb_work* and *LAPACKE_zgbequb_work*.

4.19.1820 LAPACKE_zgbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbrfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, const armpl_doublecomplex_t *ab,
                           armpl_int_t ldab, const armpl_doublecomplex_t *afb,
                           armpl_int_t ldafb, const armpl_int_t *ipiv,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbrfs*, *LAPACKE_dgbrfs*, *LAPACKE_sgbrfs* and *LAPACKE_zgbrfs*. It also exists with a native Fortran interface as *zgbrfs*.

4.19.1821 LAPACKE_zgbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbrfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab,
                                const armpl_doublecomplex_t *afb,
                                armpl_int_t ldafb, const armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1822 LAPACKE_zgbrfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbrfsx(armpl_int_t matrix_layout, char trans, char equed,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            armpl_int_t nrhs, const armpl_doublecomplex_t *ab,
                            armpl_int_t ldab,
                            const armpl_doublecomplex_t *afb,
                            armpl_int_t ldafb, const armpl_int_t *ipiv,
                            const double *r, const double *c,
                            const armpl_doublecomplex_t *b, armpl_int_t ldb,
                            armpl_doublecomplex_t *x, armpl_int_t ldx,
                            double *rcond, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1824 LAPACKE_zgbsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t kl, armpl_int_t ku, armpl_int_t nrhs,
                          armpl_doublecomplex_t *ab, armpl_int_t ldab,
                          armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsv*, *LAPACKE_dgbsv*, *LAPACKE_sgbsv* and *LAPACKE_zgbsv*. It also exists with a native Fortran interface as *zgbsv*.

4.19.1825 LAPACKE_zgbsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t kl, armpl_int_t ku,
                               armpl_int_t nrhs, armpl_doublecomplex_t *ab,
                               armpl_int_t ldab, armpl_int_t *ipiv,
                               armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsv_work*, *LAPACKE_dgbsv_work*, *LAPACKE_sgbsv_work* and *LAPACKE_zgbsv_work*.

4.19.1826 LAPACKE_zgbsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbsvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, armpl_doublecomplex_t *ab,
                           armpl_int_t ldab, armpl_doublecomplex_t *afb,
                           armpl_int_t ldafb, armpl_int_t *ipiv, char *equed,
                           double *r, double *c, armpl_doublecomplex_t *b,
                           armpl_int_t ldb, armpl_doublecomplex_t *x,
                           armpl_int_t ldx, double *rcond, double *ferr,
                           double *berr, double *rpivot);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvx*, *LAPACKE_dgbsvx*, *LAPACKE_sgbsvx* and *LAPACKE_zgbsvx*. It also exists with a native Fortran interface as *zgbsvx*.

4.19.1827 LAPACKE_zgbsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbsvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t kl,
                                armpl_int_t ku, armpl_int_t nrhs,
                                armpl_doublecomplex_t *ab, armpl_int_t ldab,
                                armpl_doublecomplex_t *afb, armpl_int_t ldafb,
                                armpl_int_t *ipiv, char *equed, double *r,
                                double *c, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvx_work*, *LAPACKE_dgbsvx_work*, *LAPACKE_sgbsvx_work* and *LAPACKE_zgbsvx_work*.

4.19.1828 LAPACKE_zgbsvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbsvxx(armpl_int_t matrix_layout, char fact, char trans,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            armpl_int_t nrhs, armpl_doublecomplex_t *ab,
                            armpl_int_t ldab, armpl_doublecomplex_t *afb,
                            armpl_int_t ldafb, armpl_int_t *ipiv, char *equed,
                            double *r, double *c, armpl_doublecomplex_t *b,
                            armpl_int_t ldb, armpl_doublecomplex_t *x,
                            armpl_int_t ldx, double *rcond, double *rpvgrw,
                            double *berr, armpl_int_t n_err_bnds,
                            double *err_bnds_norm, double *err_bnds_comp,
                            armpl_int_t nparams, double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvxx*, *LAPACKE_dgbsvxx*, *LAPACKE_sgbsvxx* and *LAPACKE_zgbsvxx*. It also exists with a native Fortran interface as *zgbsvxx*.

4.19.1829 LAPACKE_zgbsvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbsvxx_work(armpl_int_t matrix_layout, char fact,
                                 char trans, armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku, armpl_int_t nrhs,
                                 armpl_doublecomplex_t *ab, armpl_int_t ldab,
                                 armpl_doublecomplex_t *afb,
                                 armpl_int_t ldafb, armpl_int_t *ipiv,
                                 char *equed, double *r, double *c,
                                 armpl_doublecomplex_t *b, armpl_int_t ldb,
                                 armpl_doublecomplex_t *x, armpl_int_t ldx,
                                 double *rcond, double *rpvgrw, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1830 LAPACKE_zgbtrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbtrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
```

(continues on next page)

(continued from previous page)

```
                                armpl_doublecomplex_t *ab, armpl_int_t ldab,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrf*, *LAPACKE_dgbtrf*, *LAPACKE_sgbtrf* and *LAPACKE_zgbtrf*. It also exists with a native Fortran interface as *zgbtrf*.

4.19.1831 LAPACKE_zgbtrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbtrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                armpl_doublecomplex_t *ab, armpl_int_t ldab,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1832 LAPACKE_zgbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbtrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, const armpl_doublecomplex_t *ab,
                           armpl_int_t ldab, const armpl_int_t *ipiv,
                           armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrs*, *LAPACKE_dgbtrs*, *LAPACKE_sgbtrs* and *LAPACKE_zgbtrs*. It also exists with a native Fortran interface as *zgbtrs*.

4.19.1833 LAPACKE_zgbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgbtrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1834 LAPACKE_zgebak

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgebak(armpl_int_t matrix_layout, char job, char side,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           const double *scale, armpl_int_t m,
                           armpl_doublecomplex_t *v, armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebak*, *LAPACKE_dgebak*, *LAPACKE_sgebak* and *LAPACKE_zgebak*. It also exists with a native Fortran interface as *zgebak*.

4.19.1835 LAPACKE_zgebak_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgebak_work(armpl_int_t matrix_layout, char job,
                                char side, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, const double *scale,
                                armpl_int_t m, armpl_doublecomplex_t *v,
                                armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebak_work*, *LAPACKE_dgebak_work*, *LAPACKE_sgebak_work* and *LAPACKE_zgebak_work*.

4.19.1836 LAPACKE_zgebal

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgebal(armpl_int_t matrix_layout, char job, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_int_t *ilo, armpl_int_t *ihi,
                           double *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebal*, *LAPACKE_dgebal*, *LAPACKE_sgebal* and *LAPACKE_zgebal*. It also exists with a native Fortran interface as *zgebal*.

4.19.1837 LAPACKE_zgebal_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgebal_work(armpl_int_t matrix_layout, char job,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ilo,
                                armpl_int_t *ihi, double *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebal_work*, *LAPACKE_dgebal_work*, *LAPACKE_sgebal_work* and *LAPACKE_zgebal_work*.

4.19.1838 LAPACKE_zgebrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgebrd(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, double *d, double *e,
                           armpl_doublecomplex_t *tauq,
                           armpl_doublecomplex_t *taup);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebrd*, *LAPACKE_dgebrd*, *LAPACKE_sgebrd* and *LAPACKE_zgebrd*. It also exists with a native Fortran interface as *zgebrd*.

4.19.1839 LAPACKE_zgebrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgebrd_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, double *d, double *e,
                                armpl_doublecomplex_t *tauq,
                                armpl_doublecomplex_t *taup,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebrd_work*, *LAPACKE_dgebrd_work*, *LAPACKE_sgebrd_work* and *LAPACKE_zgebrd_work*.

4.19.1840 LAPACKE_zgecon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgecon(armpl_int_t matrix_layout, char norm,
                           armpl_int_t n, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgecon*, *LAPACKE_dgecon*, *LAPACKE_sgecon* and *LAPACKE_zgecon*. It also exists with a native Fortran interface as *zgecon*.

4.19.1841 LAPACKE_zgecon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgecon_work(armpl_int_t matrix_layout, char norm,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda, double anorm, double *rcond,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgecon_work*, *LAPACKE_dgecon_work*, *LAPACKE_sgecon_work* and *LAPACKE_zgecon_work*.

4.19.1842 LAPACKE_zgeequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeequ(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, double *r, double *c,
                           double *rowcnd, double *colcnd, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequ*, *LAPACKE_dgeequ*, *LAPACKE_sgeequ* and *LAPACKE_zgeequ*. It also exists with a native Fortran interface as *zgeequ*.

4.19.1843 LAPACKE_zgeequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeequ_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda, double *r, double *c,
                                double *rowcnd, double *colcnd,
                                double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequ_work*, *LAPACKE_dgeequ_work*, *LAPACKE_sgeequ_work* and *LAPACKE_zgeequ_work*.

4.19.1844 LAPACKE_zgeequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeequb(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, const armpl_doublecomplex_t *a,
                            armpl_int_t lda, double *r, double *c,
                            double *rowcnd, double *colcnd, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequb*, *LAPACKE_dgeequb*, *LAPACKE_sgeequb* and *LAPACKE_zgeequb*. It also exists with a native Fortran interface as *zgeequb*.

4.19.1845 LAPACKE_zgeequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeequb_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n,
                                 const armpl_doublecomplex_t *a,
                                 armpl_int_t lda, double *r, double *c,
                                 double *rowcnd, double *colcnd,
                                 double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequb_work*, *LAPACKE_dgeequb_work*, *LAPACKE_sgeequb_work* and *LAPACKE_zgeequb_work*.

4.19.1846 LAPACKE_zgees

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgees(armpl_int_t matrix_layout, char jobvs, char sort,
                          LAPACK_Z_SELECT1 select, armpl_int_t n,
                          armpl_doublecomplex_t *a, armpl_int_t lda,
                          armpl_int_t *sdim, armpl_doublecomplex_t *w,
                          armpl_doublecomplex_t *vs, armpl_int_t ldvs);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgees*, *LAPACKE_dgees*, *LAPACKE_sgees* and *LAPACKE_zgees*. It also exists with a native Fortran interface as *zgees*.

4.19.1847 LAPACKE_zgees_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgees_work(armpl_int_t matrix_layout, char jobvs,
                               char sort, LAPACK_Z_SELECT1 select,
                               armpl_int_t n, armpl_doublecomplex_t *a,
                               armpl_int_t lda, armpl_int_t *sdim,
                               armpl_doublecomplex_t *w,
                               armpl_doublecomplex_t *vs, armpl_int_t ldvs,
                               armpl_doublecomplex_t *work, armpl_int_t lwork,
                               double *rwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgees_work*, *LAPACKE_dgees_work*, *LAPACKE_sgees_work* and *LAPACKE_zgees_work*.

4.19.1848 LAPACKE_zgeesx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeesx(armpl_int_t matrix_layout, char jobvs, char sort,
                           LAPACK_Z_SELECT1 select, char sense, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_int_t *sdim, armpl_doublecomplex_t *w,
                           armpl_doublecomplex_t *vs, armpl_int_t ldvs,
                           double *rconde, double *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeesx*, *LAPACKE_dgeesx*, *LAPACKE_sgeesx* and *LAPACKE_zgeesx*. It also exists with a native Fortran interface as *zgeesx*.

4.19.1849 LAPACKE_zgeesx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeesx_work(armpl_int_t matrix_layout, char jobvs,
                                char sort, LAPACK_Z_SELECT1 select,
                                char sense, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_int_t *sdim, armpl_doublecomplex_t *w,
                                armpl_doublecomplex_t *vs, armpl_int_t ldvs,
                                double *rconde, double *rcondv,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeesx_work*, *LAPACKE_dgeesx_work*, *LAPACKE_sgeesx_work* and *LAPACKE_zgeesx_work*.

4.19.1850 LAPACKE_zgeev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeev(armpl_int_t matrix_layout, char jobvl, char jobvr,
                          armpl_int_t n, armpl_doublecomplex_t *a,
                          armpl_int_t lda, armpl_doublecomplex_t *w,
                          armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                          armpl_doublecomplex_t *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeev*, *LAPACKE_dgeev*, *LAPACKE_sgeev* and *LAPACKE_zgeev*. It also exists with a native Fortran interface as *zgeev*.

4.19.1851 LAPACKE_zgeev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeev_work(armpl_int_t matrix_layout, char jobvl,
                               char jobvr, armpl_int_t n,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               armpl_doublecomplex_t *w,
```

(continues on next page)

(continued from previous page)

```
                                armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                                armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                                armpl_doublecomplex_t *work, armpl_int_t lwork,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeev_work*, *LAPACKE_dgeev_work*, *LAPACKE_sgeev_work* and *LAPACKE_zgeev_work*.

4.19.1852 LAPACKE_zgeevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeevx(armpl_int_t matrix_layout, char balanc, char jobvl,
                           char jobvr, char sense, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *w,
                           armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                           armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t *ilo, armpl_int_t *ihi, double *scale,
                           double *abnrm, double *rconde, double *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeevx*, *LAPACKE_dgeevx*, *LAPACKE_sgeevx* and *LAPACKE_zgeevx*. It also exists with a native Fortran interface as *zgeevx*.

4.19.1853 LAPACKE_zgeevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeevx_work(armpl_int_t matrix_layout, char balanc,
                                char jobvl, char jobvr, char sense,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *w,
                                armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                                armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                                armpl_int_t *ilo, armpl_int_t *ihi,
                                double *scale, double *abnrm, double *rconde,
                                double *rcondv, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1854 LAPACKE_zgehrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgehrd(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t ilo, armpl_int_t ihi,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1855 LAPACKE_zgehrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgehrd_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1856 LAPACKE_zgejsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgejsv(armpl_int_t matrix_layout, char joba, char jobu,
                           char jobv, char jobr, char jobt, char jobp,
                           armpl_int_t m, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           double *sva, armpl_doublecomplex_t *u,
                           armpl_int_t ldu, armpl_doublecomplex_t *v,
                           armpl_int_t ldv, double *stat,
                           armpl_int_t *istat);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgejsv*, *LAPACKE_dgejsv*, *LAPACKE_sgejsv* and *LAPACKE_zgejsv*. It also exists with a native Fortran interface as *zgejsv*.

4.19.1857 LAPACKE_zgejsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgejsv_work(armpl_int_t matrix_layout, char joba,
                                char jobu, char jobv, char jobr, char jobt,
                                char jobp, armpl_int_t m, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                double *sva, armpl_doublecomplex_t *u,
                                armpl_int_t ldu, armpl_doublecomplex_t *v,
                                armpl_int_t ldv, armpl_doublecomplex_t *cwork,
                                armpl_int_t lwork, double *work,
                                armpl_int_t lrwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1858 LAPACKE_zgelq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelq(armpl_int_t matrix_layout, armpl_int_t m,
                          armpl_int_t n, armpl_doublecomplex_t *a,
                          armpl_int_t lda, armpl_doublecomplex_t *t,
                          armpl_int_t tsize);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq*, *LAPACKE_dgelq*, *LAPACKE_sgelq* and *LAPACKE_zgelq*. It also exists with a native Fortran interface as *zgelq*.

4.19.1859 LAPACKE_zgelq2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelq2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq2*, *LAPACKE_dgelq2*, *LAPACKE_sgelq2* and *LAPACKE_zgelq2*. It also exists with a native Fortran interface as *zgelq2*.

4.19.1860 LAPACKE_zgelq2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelq2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq2_work*, *LAPACKE_dgelq2_work*, *LAPACKE_sgelq2_work* and *LAPACKE_zgelq2_work*.

4.19.1861 LAPACKE_zgelq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelq_work(armpl_int_t matrix_layout, armpl_int_t m,
                               armpl_int_t n, armpl_doublecomplex_t *a,
                               armpl_int_t lda, armpl_doublecomplex_t *t,
                               armpl_int_t tsize, armpl_doublecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq_work*, *LAPACKE_dgelq_work*, *LAPACKE_sgelq_work* and *LAPACKE_zgelq_work*.

4.19.1862 LAPACKE_zgelqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelqf*, *LAPACKE_dgelqf*, *LAPACKE_sgelqf* and *LAPACKE_zgelqf*. It also exists with a native Fortran interface as *zgelqf*.

4.19.1863 LAPACKE_zgelqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelqf_work*, *LAPACKE_dgelqf_work*, *LAPACKE_sgelqf_work* and *LAPACKE_zgelqf_work*.

4.19.1864 LAPACKE_zgels

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgels(armpl_int_t matrix_layout, char trans,
                          armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                          armpl_doublecomplex_t *a, armpl_int_t lda,
                          armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgels*, *LAPACKE_dgels*, *LAPACKE_sgels* and *LAPACKE_zgels*. It also exists with a native Fortran interface as *zgels*.

4.19.1865 LAPACKE_zgels_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgels_work(armpl_int_t matrix_layout, char trans,
                               armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               armpl_doublecomplex_t *b, armpl_int_t ldb,
                               armpl_doublecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgels_work*, *LAPACKE_dgels_work*, *LAPACKE_sgels_work* and *LAPACKE_zgels_work*.

4.19.1866 LAPACKE_zgelsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelsd(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           double *s, double rcond, armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsd*, *LAPACKE_dgelsd*, *LAPACKE_sgelsd* and *LAPACKE_zgelsd*. It also exists with a native Fortran interface as *zgelsd*.

4.19.1867 LAPACKE_zgelsd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelsd_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                double *s, double rcond, armpl_int_t *rank,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1868 LAPACKE_zgelss

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelss(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           double *s, double rcond, armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelss*, *LAPACKE_dgelss*, *LAPACKE_sgelss* and *LAPACKE_zgelss*. It also exists with a native Fortran interface as *zgelss*.

4.19.1869 LAPACKE_zgelss_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelss_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                double *s, double rcond, armpl_int_t *rank,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1870 LAPACKE_zgelsy

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelsy(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_int_t *jpvt, double rcond,
                           armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsy*, *LAPACKE_dgelsy*, *LAPACKE_sgelsy* and *LAPACKE_zgelsy*. It also exists with a native Fortran interface as *zgelsy*.

4.19.1871 LAPACKE_zgelsy_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgelsy_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_int_t *jpvt, double rcond,
                                armpl_int_t *rank,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsy_work*, *LAPACKE_dgelsy_work*, *LAPACKE_sgelsy_work* and *LAPACKE_zgelsy_work*.

4.19.1872 LAPACKE_zgemlq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgemlq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *t, armpl_int_t tsize,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemlq*, *LAPACKE_dgemlq*, *LAPACKE_sgemlq* and *LAPACKE_zgemlq*. It also exists with a native Fortran interface as *zgemlq*.

4.19.1873 LAPACKE_zgemlq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgemlq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *t,
                                armpl_int_t tsize, armpl_doublecomplex_t *c,
                                armpl_int_t ldc, armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemlq_work*, *LAPACKE_dgemlq_work*, *LAPACKE_sgemlq_work* and *LAPACKE_zgemlq_work*.

4.19.1874 LAPACKE_zgemqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgemqr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *t, armpl_int_t tsize,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqr*, *LAPACKE_dgemqr*, *LAPACKE_sgemqr* and *LAPACKE_zgemqr*. It also exists with a native Fortran interface as *zgemqr*.

4.19.1875 LAPACKE_zgemqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgemqr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *t,
                                armpl_int_t tsize, armpl_doublecomplex_t *c,
                                armpl_int_t ldc, armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqr_work*, *LAPACKE_dgemqr_work*, *LAPACKE_sgemqr_work* and *LAPACKE_zgemqr_work*.

4.19.1876 LAPACKE_zgemqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgemqrt(armpl_int_t matrix_layout, char side, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t k,
                            armpl_int_t nb, const armpl_doublecomplex_t *v,
                            armpl_int_t ldv, const armpl_doublecomplex_t *t,
                            armpl_int_t ldt, armpl_doublecomplex_t *c,
                            armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqrt*, *LAPACKE_dgemqrt*, *LAPACKE_sgemqrt* and *LAPACKE_zgemqrt*. It also exists with a native Fortran interface as *zgemqrt*.

4.19.1877 LAPACKE_zgemqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgemqrt_work(armpl_int_t matrix_layout, char side,
                                 char trans, armpl_int_t m, armpl_int_t n,
                                 armpl_int_t k, armpl_int_t nb,
```

(continues on next page)

(continued from previous page)

```
                                const armpl_doublecomplex_t *v,
                                armpl_int_t ldv,
                                const armpl_doublecomplex_t *t,
                                armpl_int_t ldt, armpl_doublecomplex_t *c,
                                armpl_int_t ldc,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqrt_work*, *LAPACKE_dgemqrt_work*, *LAPACKE_sgemqrt_work* and *LAPACKE_zgemqrt_work*.

4.19.1878 LAPACKE_zgeqlf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqlf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqlf*, *LAPACKE_dgeqlf*, *LAPACKE_sgeqlf* and *LAPACKE_zgeqlf*. It also exists with a native Fortran interface as *zgeqlf*.

4.19.1879 LAPACKE_zgeqlf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqlf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqlf_work*, *LAPACKE_dgeqlf_work*, *LAPACKE_sgeqlf_work* and *LAPACKE_zgeqlf_work*.

4.19.1880 LAPACKE_zgeqp3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqp3(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *jpvt,
                           armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqp3*, *LAPACKE_dgeqp3*, *LAPACKE_sgeqp3* and *LAPACKE_zgeqp3*. It also exists with a native Fortran interface as *zgeqp3*.

4.19.1881 LAPACKE_zgeqp3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqp3_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *jpvt,
                                armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqp3_work*, *LAPACKE_dgeqp3_work*, *LAPACKE_sgeqp3_work* and *LAPACKE_zgeqp3_work*.

4.19.1882 LAPACKE_zgeqpf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqpf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *jpvt,
                           armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqpf*, *LAPACKE_dgeqpf*, *LAPACKE_sgeqpf* and *LAPACKE_zgeqpf*.

4.19.1883 LAPACKE_zgeqpf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqpf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *jpvt,
                                armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqpf_work*, *LAPACKE_dgeqpf_work*, *LAPACKE_sgeqpf_work* and *LAPACKE_zgeqpf_work*.

4.19.1884 LAPACKE_zgeqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqr(armpl_int_t matrix_layout, armpl_int_t m,
                          armpl_int_t n, armpl_doublecomplex_t *a,
                          armpl_int_t lda, armpl_doublecomplex_t *t,
                          armpl_int_t tsize);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr*, *LAPACKE_dgeqr*, *LAPACKE_sgeqr* and *LAPACKE_zgeqr*. It also exists with a native Fortran interface as *zgeqr*.

4.19.1885 LAPACKE_zgeqr2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqr2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr2*, *LAPACKE_dgeqr2*, *LAPACKE_sgeqr2* and *LAPACKE_zgeqr2*. It also exists with a native Fortran interface as *zgeqr2*.

4.19.1886 LAPACKE_zgeqr2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqr2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr2_work*, *LAPACKE_dgeqr2_work*, *LAPACKE_sgeqr2_work* and *LAPACKE_zgeqr2_work*.

4.19.1887 LAPACKE_zgeqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqr_work(armpl_int_t matrix_layout, armpl_int_t m,
                               armpl_int_t n, armpl_doublecomplex_t *a,
                               armpl_int_t lda, armpl_doublecomplex_t *t,
                               armpl_int_t tsize, armpl_doublecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr_work*, *LAPACKE_dgeqr_work*, *LAPACKE_sgeqr_work* and *LAPACKE_zgeqr_work*.

4.19.1888 LAPACKE_zgeqrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrf*, *LAPACKE_dgeqrf*, *LAPACKE_sgeqrf* and *LAPACKE_zgeqrf*. It also exists with a native Fortran interface as *zgeqrf*.

4.19.1889 LAPACKE_zgeqrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrf_work*, *LAPACKE_dgeqrf_work*, *LAPACKE_sgeqrf_work* and *LAPACKE_zgeqrf_work*.

4.19.1890 LAPACKE_zgeqrfp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrfp(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_doublecomplex_t *a,
                            armpl_int_t lda, armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrfp*, *LAPACKE_dgeqrfp*, *LAPACKE_sgeqrfp* and *LAPACKE_zgeqrfp*. It also exists with a native Fortran interface as *zgeqrfp*.

4.19.1891 LAPACKE_zgeqrfp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrfp_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, armpl_doublecomplex_t *tau,
                                 armpl_doublecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrfp_work*, *LAPACKE_dgeqrfp_work*, *LAPACKE_sgeqrfp_work* and *LAPACKE_zgeqrfp_work*.

4.19.1892 LAPACKE_zgeqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrt(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nb,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt*, *LAPACKE_dgeqrt*, *LAPACKE_sgeqrt* and *LAPACKE_zgeqrt*. It also exists with a native Fortran interface as *zgeqrt*.

4.19.1893 LAPACKE_zgeqrt2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrt2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_doublecomplex_t *a,
                            armpl_int_t lda, armpl_doublecomplex_t *t,
                            armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt2*, *LAPACKE_dgeqrt2*, *LAPACKE_sgeqrt2* and *LAPACKE_zgeqrt2*. It also exists with a native Fortran interface as *zgeqrt2*.

4.19.1894 LAPACKE_zgeqrt2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrt2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, armpl_doublecomplex_t *t,
                                 armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt2_work*, *LAPACKE_dgeqrt2_work*, *LAPACKE_sgeqrt2_work* and *LAPACKE_zgeqrt2_work*.

4.19.1895 LAPACKE_zgeqrt3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrt3(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_doublecomplex_t *a,
                            armpl_int_t lda, armpl_doublecomplex_t *t,
                            armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt3*, *LAPACKE_dgeqrt3*, *LAPACKE_sgeqrt3* and *LAPACKE_zgeqrt3*. It also exists with a native Fortran interface as *zgeqrt3*.

4.19.1896 LAPACKE_zgeqrt3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrt3_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, armpl_doublecomplex_t *t,
                                 armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt3_work*, *LAPACKE_dgeqrt3_work*, *LAPACKE_sgeqrt3_work* and *LAPACKE_zgeqrt3_work*.

4.19.1897 LAPACKE_zgeqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgeqrt_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nb,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *t, armpl_int_t ldt,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt_work*, *LAPACKE_dgeqrt_work*, *LAPACKE_sgeqrt_work* and *LAPACKE_zgeqrt_work*.

4.19.1898 LAPACKE_zgerfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgerfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *af, armpl_int_t ldaf,
                           const armpl_int_t *ipiv,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfs*, *LAPACKE_dgerfs*, *LAPACKE_sgerfs* and *LAPACKE_zgerfs*. It also exists with a native Fortran interface as *zgerfs*.

4.19.1899 LAPACKE_zgerfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgerfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *af,
                                armpl_int_t ldaf, const armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfs_work*, *LAPACKE_dgerfs_work*, *LAPACKE_sgerfs_work* and *LAPACKE_zgerfs_work*.

4.19.1900 LAPACKE_zgerfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgerfsx(armpl_int_t matrix_layout, char trans, char equed,
                            armpl_int_t n, armpl_int_t nrhs,
                            const armpl_doublecomplex_t *a, armpl_int_t lda,
                            const armpl_doublecomplex_t *af, armpl_int_t ldaf,
                            const armpl_int_t *ipiv, const double *r,
                            const double *c, const armpl_doublecomplex_t *b,
                            armpl_int_t ldb, armpl_doublecomplex_t *x,
                            armpl_int_t ldx, double *rcond, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfsx*, *LAPACKE_dgerfsx*, *LAPACKE_sgerfsx* and *LAPACKE_zgerfsx*. It also exists with a native Fortran interface as *zgerfsx*.

4.19.1901 LAPACKE_zgerfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgerfsx_work(armpl_int_t matrix_layout, char trans,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const armpl_doublecomplex_t *a,
                                 armpl_int_t lda,
                                 const armpl_doublecomplex_t *af,
                                 armpl_int_t ldaf, const armpl_int_t *ipiv,
                                 const double *r, const double *c,
                                 const armpl_doublecomplex_t *b,
                                 armpl_int_t ldb, armpl_doublecomplex_t *x,
                                 armpl_int_t ldx, double *rcond, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfsx_work*, *LAPACKE_dgerfsx_work*, *LAPACKE_sgerfsx_work* and *LAPACKE_zgerfsx_work*.

4.19.1902 LAPACKE_zgerqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgerqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerqf*, *LAPACKE_dgerqf*, *LAPACKE_sgerqf* and *LAPACKE_zgerqf*. It also exists with a native Fortran interface as *zgerqf*.

4.19.1903 LAPACKE_zgerqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgerqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerqf_work*, *LAPACKE_dgerqf_work*, *LAPACKE_sgerqf_work* and *LAPACKE_zgerqf_work*.

4.19.1904 LAPACKE_zgesdd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesdd(armpl_int_t matrix_layout, char jobz,
                           armpl_int_t m, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           double *s, armpl_doublecomplex_t *u,
                           armpl_int_t ldu, armpl_doublecomplex_t *vt,
                           armpl_int_t ldvt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesdd*, *LAPACKE_dgesdd*, *LAPACKE_sgesdd* and *LAPACKE_zgesdd*. It also exists with a native Fortran interface as *zgesdd*.

4.19.1905 LAPACKE_zgesdd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesdd_work(armpl_int_t matrix_layout, char jobz,
                                armpl_int_t m, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                double *s, armpl_doublecomplex_t *u,
                                armpl_int_t ldu, armpl_doublecomplex_t *vt,
                                armpl_int_t ldvt, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1906 LAPACKE_zgesv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, armpl_doublecomplex_t *a,
                          armpl_int_t lda, armpl_int_t *ipiv,
                          armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1907 LAPACKE_zgesv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, armpl_doublecomplex_t *a,
                               armpl_int_t lda, armpl_int_t *ipiv,
                               armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1908 LAPACKE_zgesvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvd(armpl_int_t matrix_layout, char jobu, char jobvt,
                           armpl_int_t m, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           double *s, armpl_doublecomplex_t *u,
                           armpl_int_t ldu, armpl_doublecomplex_t *vt,
                           armpl_int_t ldvt, double *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1909 LAPACKE_zgesvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvd_work(armpl_int_t matrix_layout, char jobu,
                                char jobvt, armpl_int_t m, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                double *s, armpl_doublecomplex_t *u,
                                armpl_int_t ldu, armpl_doublecomplex_t *vt,
                                armpl_int_t ldvt, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvd_work*, *LAPACKE_dgesvd_work*, *LAPACKE_sgesvd_work* and *LAPACKE_zgesvd_work*.

4.19.1910 LAPACKE_zgesvdx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvdx(armpl_int_t matrix_layout, char jobu, char jobvt,
                            char range, armpl_int_t m, armpl_int_t n,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            double vl, double vu, armpl_int_t il,
                            armpl_int_t iu, armpl_int_t *ns, double *s,
                            armpl_doublecomplex_t *u, armpl_int_t ldu,
                            armpl_doublecomplex_t *vt, armpl_int_t ldvt,
                            armpl_int_t *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvdx*, *LAPACKE_dgesvdx*, *LAPACKE_sgesvdx* and *LAPACKE_zgesvdx*. It also exists with a native Fortran interface as *zgesvdx*.

4.19.1911 LAPACKE_zgesvdx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvdx_work(armpl_int_t matrix_layout, char jobu,
                                 char jobvt, char range, armpl_int_t m,
                                 armpl_int_t n, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, double vl, double vu,
                                 armpl_int_t il, armpl_int_t iu,
                                 armpl_int_t *ns, double *s,
                                 armpl_doublecomplex_t *u, armpl_int_t ldu,
                                 armpl_doublecomplex_t *vt, armpl_int_t ldvt,
```

(continues on next page)

(continued from previous page)

```
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1912 LAPACKE_zgesvj

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvj(armpl_int_t matrix_layout, char joba, char jobu,
                           char jobv, armpl_int_t m, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           double *sva, armpl_int_t mv,
                           armpl_doublecomplex_t *v, armpl_int_t ldv,
                           double *stat);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvj*, *LAPACKE_dgesvj*, *LAPACKE_sgesvj* and *LAPACKE_zgesvj*. It also exists with a native Fortran interface as *zgesvj*.

4.19.1913 LAPACKE_zgesvj_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvj_work(armpl_int_t matrix_layout, char joba,
                                char jobu, char jobv, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, double *sva, armpl_int_t mv,
                                armpl_doublecomplex_t *v, armpl_int_t ldv,
                                armpl_doublecomplex_t *cwork,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t lrwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvj_work*, *LAPACKE_dgesvj_work*, *LAPACKE_sgesvj_work* and *LAPACKE_zgesvj_work*.

4.19.1914 LAPACKE_zgesvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, char *equed, double *r,
                           double *c, armpl_doublecomplex_t *b,
                           armpl_int_t ldb, armpl_doublecomplex_t *x,
                           armpl_int_t ldx, double *rcond, double *ferr,
                           double *berr, double *rpivot);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvx*, *LAPACKE_dgesvx*, *LAPACKE_sgesvx* and *LAPACKE_zgesvx*. It also exists with a native Fortran interface as *zgesvx*.

4.19.1915 LAPACKE_zgesvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t nrhs,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *af, armpl_int_t ldaf,
                                armpl_int_t *ipiv, char *equed, double *r,
                                double *c, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvx_work*, *LAPACKE_dgesvx_work*, *LAPACKE_sgesvx_work* and *LAPACKE_zgesvx_work*.

4.19.1916 LAPACKE_zgesvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvxx(armpl_int_t matrix_layout, char fact, char trans,
                            armpl_int_t n, armpl_int_t nrhs,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            armpl_doublecomplex_t *af, armpl_int_t ldaf,

                            double *c, armpl_doublecomplex_t *b,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *rpvgrw,
                                double *berr, armpl_int_t n_err_bnds,
                                double *err_bnds_norm, double *err_bnds_comp,
                                armpl_int_t nparams, double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvxx*, *LAPACKE_dgesvxx*, *LAPACKE_sgesvxx* and *LAPACKE_zgesvxx*. It also exists with a native Fortran interface as *zgesvxx*.

4.19.1917 LAPACKE_zgesvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgesvxx_work(armpl_int_t matrix_layout, char fact,
                                 char trans, armpl_int_t n, armpl_int_t nrhs,
                                 armpl_doublecomplex_t *a, armpl_int_t lda,
                                 armpl_doublecomplex_t *af, armpl_int_t ldaf,
                                 armpl_int_t *ipiv, char *equed, double *r,
                                 double *c, armpl_doublecomplex_t *b,
                                 armpl_int_t ldb, armpl_doublecomplex_t *x,
                                 armpl_int_t ldx, double *rcond,
                                 double *rpvgrw, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvxx_work*, *LAPACKE_dgesvxx_work*, *LAPACKE_sgesvxx_work* and *LAPACKE_zgesvxx_work*.

4.19.1918 LAPACKE_zgetf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetf2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetf2*, *LAPACKE_dgetf2*, *LAPACKE_sgetf2* and *LAPACKE_zgetf2*. It also exists with a native Fortran interface as *zgetf2*.

4.19.1919 LAPACKE_zgetf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetf2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1920 LAPACKE_zgetrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf*, *LAPACKE_dgetrf*, *LAPACKE_sgetrf* and *LAPACKE_zgetrf*. It also exists with a native Fortran interface as *zgetrf*.

4.19.1921 LAPACKE_zgetrf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetrf2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_doublecomplex_t *a,
                            armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1922 LAPACKE_zgetrf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetrf2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1923 LAPACKE_zgetrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1924 LAPACKE_zgetri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetri(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1925 LAPACKE_zgetri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetri_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetri_work*, *LAPACKE_dgetri_work*, *LAPACKE_sgetri_work* and *LAPACKE_zgetri_work*.

4.19.1926 LAPACKE_zgetrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrs*, *LAPACKE_dgetrs*, *LAPACKE_sgetrs* and *LAPACKE_zgetrs*. It also exists with a native Fortran interface as *zgetrs*.

4.19.1927 LAPACKE_zgetrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrs_work*, *LAPACKE_dgetrs_work*, *LAPACKE_sgetrs_work* and *LAPACKE_zgetrs_work*.

4.19.1928 LAPACKE_zgetsls

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetsls(armpl_int_t matrix_layout, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetsls*, *LAPACKE_dgetsls*, *LAPACKE_sgetsls* and *LAPACKE_zgetsls*. It also exists with a native Fortran interface as *zgetsls*.

4.19.1929 LAPACKE_zgetsls_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgetsls_work(armpl_int_t matrix_layout, char trans,
                                 armpl_int_t m, armpl_int_t n,
                                 armpl_int_t nrhs, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, armpl_doublecomplex_t *b,
                                 armpl_int_t ldb, armpl_doublecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetsls_work*, *LAPACKE_dgetsls_work*, *LAPACKE_sgetsls_work* and *LAPACKE_zgetsls_work*.

4.19.1930 LAPACKE_zggbak

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggbak(armpl_int_t matrix_layout, char job, char side,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           const double *lscale, const double *rscale,
                           armpl_int_t m, armpl_doublecomplex_t *v,
                           armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbak*, *LAPACKE_dggbak*, *LAPACKE_sggbak* and *LAPACKE_zggbak*. It also exists with a native Fortran interface as *zggbak*.

4.19.1931 LAPACKE_zggbak_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggbak_work(armpl_int_t matrix_layout, char job,
                                char side, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, const double *lscale,
                                const double *rscale, armpl_int_t m,
                                armpl_doublecomplex_t *v, armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbak_work*, *LAPACKE_dggbak_work*, *LAPACKE_sggbak_work* and *LAPACKE_zggbak_work*.

4.19.1932 LAPACKE_zggbal

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggbal(armpl_int_t matrix_layout, char job, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_int_t *ilo, armpl_int_t *ihi, double *lscale,
                           double *rscale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbal*, *LAPACKE_dggbal*, *LAPACKE_sggbal* and *LAPACKE_zggbal*. It also exists with a native Fortran interface as *zggbal*.

4.19.1933 LAPACKE_zggbal_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggbal_work(armpl_int_t matrix_layout, char job,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_int_t *ilo,
                                armpl_int_t *ihi, double *lscale,
                                double *rscale, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbal_work*, *LAPACKE_dggbal_work*, *LAPACKE_sggbal_work* and *LAPACKE_zggbal_work*.

4.19.1934 LAPACKE_zgges

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgges(armpl_int_t matrix_layout, char jobvsl, char jobvsr,
                          char sort, LAPACK_Z_SELECT2 selctg, armpl_int_t n,
                          armpl_doublecomplex_t *a, armpl_int_t lda,
                          armpl_doublecomplex_t *b, armpl_int_t ldb,
                          armpl_int_t *sdim, armpl_doublecomplex_t *alpha,
                          armpl_doublecomplex_t *beta,
                          armpl_doublecomplex_t *vsl, armpl_int_t ldvsl,
                          armpl_doublecomplex_t *vsr, armpl_int_t ldvsr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgges*, *LAPACKE_dgges*, *LAPACKE_sgges* and *LAPACKE_zgges*. It also exists with a native Fortran interface as *zgges*.

4.19.1935 LAPACKE_zgges3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgges3(armpl_int_t matrix_layout, char jobvsl,
                           char jobvsr, char sort, LAPACK_Z_SELECT2 selctg,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *b,
                           armpl_int_t ldb, armpl_int_t *sdim,
                           armpl_doublecomplex_t *alpha,
                           armpl_doublecomplex_t *beta,
                           armpl_doublecomplex_t *vsl, armpl_int_t ldvsl,
                           armpl_doublecomplex_t *vsr, armpl_int_t ldvsr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgges3*, *LAPACKE_dgges3*, *LAPACKE_sgges3* and *LAPACKE_zgges3*. It also exists with a native Fortran interface as *zgges3*.

4.19.1936 LAPACKE_zgges3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgges3_work(armpl_int_t matrix_layout, char jobvsl,
                                char jobvsr, char sort,
                                LAPACK_Z_SELECT2 selctg, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_int_t *sdim,
                                armpl_doublecomplex_t *alpha,
                                armpl_doublecomplex_t *beta,
                                armpl_doublecomplex_t *vsl, armpl_int_t ldvsl,
                                armpl_doublecomplex_t *vsr, armpl_int_t ldvsr,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgges3_work*, *LAPACKE_dgges3_work*, *LAPACKE_sgges3_work* and *LAPACKE_zgges3_work*.

4.19.1937 LAPACKE_zgges_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgges_work(armpl_int_t matrix_layout, char jobvsl,
                               char jobvsr, char sort,
                               LAPACK_Z_SELECT2 selctg, armpl_int_t n,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               armpl_doublecomplex_t *b, armpl_int_t ldb,
                               armpl_int_t *sdim,
                               armpl_doublecomplex_t *alpha,
                               armpl_doublecomplex_t *beta,
                               armpl_doublecomplex_t *vsl, armpl_int_t ldvsl,
                               armpl_doublecomplex_t *vsr, armpl_int_t ldvsr,
                               armpl_doublecomplex_t *work, armpl_int_t lwork,
                               double *rwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1938 LAPACKE_zggesx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggesx(armpl_int_t matrix_layout, char jobvsl,
                           char jobvsr, char sort, LAPACK_Z_SELECT2 selctg,
                           char sense, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_int_t *sdim, armpl_doublecomplex_t *alpha,
                           armpl_doublecomplex_t *beta,
                           armpl_doublecomplex_t *vsl, armpl_int_t ldvsl,
                           armpl_doublecomplex_t *vsr, armpl_int_t ldvsr,
                           double *rconde, double *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggesx*, *LAPACKE_dggesx*, *LAPACKE_sggesx* and *LAPACKE_zggesx*. It also exists with a native Fortran interface as *zggesx*.

4.19.1939 LAPACKE_zggesx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggesx_work(armpl_int_t matrix_layout, char jobvsl,
                                char jobvsr, char sort,
                                LAPACK_Z_SELECT2 selctg, char sense,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_int_t *sdim,
                                armpl_doublecomplex_t *alpha,
                                armpl_doublecomplex_t *beta,
                                armpl_doublecomplex_t *vsl, armpl_int_t ldvsl,
                                armpl_doublecomplex_t *vsr, armpl_int_t ldvsr,
                                double *rconde, double *rcondv,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t *iwork, armpl_int_t liwork,
                                armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1940 LAPACKE_zggev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggev(armpl_int_t matrix_layout, char jobvl, char jobvr,
                          armpl_int_t n, armpl_doublecomplex_t *a,
                          armpl_int_t lda, armpl_doublecomplex_t *b,
                          armpl_int_t ldb, armpl_doublecomplex_t *alpha,
                          armpl_doublecomplex_t *beta,
                          armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                          armpl_doublecomplex_t *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1941 LAPACKE_zggev3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggev3(armpl_int_t matrix_layout, char jobvl, char jobvr,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *b,
                           armpl_int_t ldb, armpl_doublecomplex_t *alpha,
                           armpl_doublecomplex_t *beta,
                           armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                           armpl_doublecomplex_t *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1942 LAPACKE_zggev3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggev3_work(armpl_int_t matrix_layout, char jobvl,
                                char jobvr, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *alpha,
                                armpl_doublecomplex_t *beta,
                                armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                                armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev3_work*, *LAPACKE_dggev3_work*, *LAPACKE_sggev3_work* and *LAPACKE_zggev3_work*.

4.19.1943 LAPACKE_zggev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggev_work(armpl_int_t matrix_layout, char jobvl,
                               char jobvr, armpl_int_t n,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               armpl_doublecomplex_t *b, armpl_int_t ldb,
                               armpl_doublecomplex_t *alpha,
                               armpl_doublecomplex_t *beta,
                               armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                               armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                               armpl_doublecomplex_t *work, armpl_int_t lwork,
                               double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggev_work*, *LAPACKE_dggev_work*, *LAPACKE_sggev_work* and *LAPACKE_zggev_work*.

4.19.1944 LAPACKE_zggevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggevx(armpl_int_t matrix_layout, char balanc, char jobvl,
                           char jobvr, char sense, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *alpha,
                           armpl_doublecomplex_t *beta,
                           armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                           armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t *ilo, armpl_int_t *ihi, double *lscale,
                           double *rscale, double *abnrm, double *bbnrm,
                           double *rconde, double *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggevx*, *LAPACKE_dggevx*, *LAPACKE_sggevx* and *LAPACKE_zggevx*. It also exists with a native Fortran interface as *zggevx*.

4.19.1945 LAPACKE_zggevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggevx_work(armpl_int_t matrix_layout, char balanc,
                                char jobvl, char jobvr, char sense,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *alpha,
                                armpl_doublecomplex_t *beta,
                                armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                                armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                                armpl_int_t *ilo, armpl_int_t *ihi,
                                double *lscale, double *rscale, double *abnrm,
                                double *bbnrm, double *rconde, double *rcondv,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t *iwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggevx_work*, *LAPACKE_dggevx_work*, *LAPACKE_sggevx_work* and *LAPACKE_zggevx_work*.

4.19.1946 LAPACKE_zggglm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggglm(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t m, armpl_int_t p,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *d, armpl_doublecomplex_t *x,
                           armpl_doublecomplex_t *y);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggglm*, *LAPACKE_dggglm*, *LAPACKE_sggglm* and *LAPACKE_zggglm*. It also exists with a native Fortran interface as *zggglm*.

4.19.1947 LAPACKE_zggglm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggglm_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t m, armpl_int_t p,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *d,
                                armpl_doublecomplex_t *x,
                                armpl_doublecomplex_t *y,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggglm_work*, *LAPACKE_dggglm_work*, *LAPACKE_sggglm_work* and *LAPACKE_zggglm_work*.

4.19.1948 LAPACKE_zgghd3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgghd3(armpl_int_t matrix_layout, char compq, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *q, armpl_int_t ldq,
                           armpl_doublecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghd3*, *LAPACKE_dgghd3*, *LAPACKE_sgghd3* and *LAPACKE_zgghd3*. It also exists with a native Fortran interface as *zgghd3*.

4.19.1949 LAPACKE_zgghd3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgghd3_work(armpl_int_t matrix_layout, char compq,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *q,
                                armpl_int_t ldq, armpl_doublecomplex_t *z,
                                armpl_int_t ldz, armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghd3_work*, *LAPACKE_dgghd3_work*, *LAPACKE_sgghd3_work* and *LAPACKE_zgghd3_work*.

4.19.1950 LAPACKE_zgghrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgghrd(armpl_int_t matrix_layout, char compq, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *q, armpl_int_t ldq,
                           armpl_doublecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgghrd*, *LAPACKE_dgghrd*, *LAPACKE_sgghrd* and *LAPACKE_zgghrd*. It also exists with a native Fortran interface as *zgghrd*.

4.19.1951 LAPACKE_zgghrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgghrd_work(armpl_int_t matrix_layout, char compq,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *q,
                                armpl_int_t ldq, armpl_doublecomplex_t *z,
                                armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1952 LAPACKE_zgglse

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgglse(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t p,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *c, armpl_doublecomplex_t *d,
                           armpl_doublecomplex_t *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgglse*, *LAPACKE_dgglse*, *LAPACKE_sgglse* and *LAPACKE_zgglse*. It also exists with a native Fortran interface as *zgglse*.

4.19.1953 LAPACKE_zgglse_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgglse_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t p,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *c,
                                armpl_doublecomplex_t *d,
                                armpl_doublecomplex_t *x,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1954 LAPACKE_zggqrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggqrf(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t m, armpl_int_t p,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *taua,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *taub);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggqrf*, *LAPACKE_dggqrf*, *LAPACKE_sggqrf* and *LAPACKE_zggqrf*. It also exists with a native Fortran interface as *zggqrf*.

4.19.1955 LAPACKE_zggqrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggqrf_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t m, armpl_int_t p,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *taua,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *taub,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggqrf_work*, *LAPACKE_dggqrf_work*, *LAPACKE_sggqrf_work* and *LAPACKE_zggqrf_work*.

4.19.1956 LAPACKE_zggrqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggrqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t p, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *taua,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *taub);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggrqf*, *LAPACKE_dggrqf*, *LAPACKE_sggrqf* and *LAPACKE_zggrqf*. It also exists with a native Fortran interface as *zggrqf*.

4.19.1957 LAPACKE_zggrqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggrqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *taua,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *taub,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggrqf_work*, *LAPACKE_dggrqf_work*, *LAPACKE_sggrqf_work* and *LAPACKE_zggrqf_work*.

4.19.1958 LAPACKE_zggsvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggsvd(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t n,
                           armpl_int_t p, armpl_int_t *k, armpl_int_t *l,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           double *alpha, double *beta,
                           armpl_doublecomplex_t *u, armpl_int_t ldu,
                           armpl_doublecomplex_t *v, armpl_int_t ldv,
                           armpl_doublecomplex_t *q, armpl_int_t ldq,
                           armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd*, *LAPACKE_dggsvd*, *LAPACKE_sggsvd* and *LAPACKE_zggsvd*.

4.19.1959 LAPACKE_zggsvd3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggsvd3(armpl_int_t matrix_layout, char jobu, char jobv,
                            char jobq, armpl_int_t m, armpl_int_t n,
                            armpl_int_t p, armpl_int_t *k, armpl_int_t *l,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            armpl_doublecomplex_t *b, armpl_int_t ldb,
                            double *alpha, double *beta,
                            armpl_doublecomplex_t *u, armpl_int_t ldu,
                            armpl_doublecomplex_t *v, armpl_int_t ldv,
                            armpl_doublecomplex_t *q, armpl_int_t ldq,
                            armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd3*, *LAPACKE_dggsvd3*, *LAPACKE_sggsvd3* and *LAPACKE_zggsvd3*. It also exists with a native Fortran interface as *zggsvd3*.

4.19.1960 LAPACKE_zggsvd3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggsvd3_work(armpl_int_t matrix_layout, char jobu,
                                 char jobv, char jobq, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t p, armpl_int_t *k,
                                 armpl_int_t *l, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, armpl_doublecomplex_t *b,
                                 armpl_int_t ldb, double *alpha, double *beta,
                                 armpl_doublecomplex_t *u, armpl_int_t ldu,
                                 armpl_doublecomplex_t *v, armpl_int_t ldv,
                                 armpl_doublecomplex_t *q, armpl_int_t ldq,
                                 armpl_doublecomplex_t *work,
                                 armpl_int_t lwork, double *rwork,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd3_work*, *LAPACKE_dggsvd3_work*, *LAPACKE_sggsvd3_work* and *LAPACKE_zggsvd3_work*.

4.19.1961 LAPACKE_zggsvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggsvd_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t n, armpl_int_t p, armpl_int_t *k,
                                armpl_int_t *l, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, double *alpha, double *beta,
                                armpl_doublecomplex_t *u, armpl_int_t ldu,
                                armpl_doublecomplex_t *v, armpl_int_t ldv,
                                armpl_doublecomplex_t *q, armpl_int_t ldq,
                                armpl_doublecomplex_t *work, double *rwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvd_work*, *LAPACKE_dggsvd_work*, *LAPACKE_sggsvd_work* and *LAPACKE_zggsvd_work*.

4.19.1962 LAPACKE_zggsvp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggsvp(armpl_int_t matrix_layout, char jobu, char jobv,
                           char jobq, armpl_int_t m, armpl_int_t p,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *b,
                           armpl_int_t ldb, double tola, double tolb,
```

(continues on next page)

(continued from previous page)

```
                            armpl_int_t *k, armpl_int_t *l,
                            armpl_doublecomplex_t *u, armpl_int_t ldu,
                            armpl_doublecomplex_t *v, armpl_int_t ldv,
                            armpl_doublecomplex_t *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp*, *LAPACKE_dggsvp*, *LAPACKE_sggsvp* and *LAPACKE_zggsvp*.

4.19.1963 LAPACKE_zggsvp3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggsvp3(armpl_int_t matrix_layout, char jobu, char jobv,
                            char jobq, armpl_int_t m, armpl_int_t p,
                            armpl_int_t n, armpl_doublecomplex_t *a,
                            armpl_int_t lda, armpl_doublecomplex_t *b,
                            armpl_int_t ldb, double tola, double tolb,
                            armpl_int_t *k, armpl_int_t *l,
                            armpl_doublecomplex_t *u, armpl_int_t ldu,
                            armpl_doublecomplex_t *v, armpl_int_t ldv,
                            armpl_doublecomplex_t *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggsvp3*, *LAPACKE_dggsvp3*, *LAPACKE_sggsvp3* and *LAPACKE_zggsvp3*. It also exists with a native Fortran interface as *zggsvp3*.

4.19.1964 LAPACKE_zggsvp3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zggsvp3_work(armpl_int_t matrix_layout, char jobu,
                                 char jobv, char jobq, armpl_int_t m,
                                 armpl_int_t p, armpl_int_t n,
                                 armpl_doublecomplex_t *a, armpl_int_t lda,
                                 armpl_doublecomplex_t *b, armpl_int_t ldb,
                                 double tola, double tolb, armpl_int_t *k,
                                 armpl_int_t *l, armpl_doublecomplex_t *u,
                                 armpl_int_t ldu, armpl_doublecomplex_t *v,
                                 armpl_int_t ldv, armpl_doublecomplex_t *q,
                                 armpl_int_t ldq, armpl_int_t *iwork,
                                 double *rwork, armpl_doublecomplex_t *tau,
                                 armpl_doublecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1966 LAPACKE_zgtcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgtcon(char norm, armpl_int_t n,
                           const armpl_doublecomplex_t *dl,
                           const armpl_doublecomplex_t *d,
                           const armpl_doublecomplex_t *du,
                           const armpl_doublecomplex_t *du2,
                           const armpl_int_t *ipiv, double anorm,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1968 LAPACKE_zgtrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgtrfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *dl,
                           const armpl_doublecomplex_t *d,
                           const armpl_doublecomplex_t *du,
                           const armpl_doublecomplex_t *dlf,
                           const armpl_doublecomplex_t *df,
                           const armpl_doublecomplex_t *duf,
                           const armpl_doublecomplex_t *du2,
                           const armpl_int_t *ipiv,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1969 LAPACKE_zgtrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgtrfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *dl,
                                const armpl_doublecomplex_t *d,
                                const armpl_doublecomplex_t *du,
                                const armpl_doublecomplex_t *dlf,
                                const armpl_doublecomplex_t *df,
                                const armpl_doublecomplex_t *duf,
                                const armpl_doublecomplex_t *du2,
                                const armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtrfs_work*, *LAPACKE_dgtrfs_work*, *LAPACKE_sgtrfs_work* and *LAPACKE_zgtrfs_work*.

4.19.1970 LAPACKE_zgtsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgtsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, armpl_doublecomplex_t *dl,
                          armpl_doublecomplex_t *d, armpl_doublecomplex_t *du,
                          armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsv*, *LAPACKE_dgtsv*, *LAPACKE_sgtsv* and *LAPACKE_zgtsv*. It also exists with a native Fortran interface as *zgtsv*.

4.19.1971 LAPACKE_zgtsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgtsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, armpl_doublecomplex_t *dl,
                               armpl_doublecomplex_t *d,
                               armpl_doublecomplex_t *du,
                               armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsv_work*, *LAPACKE_dgtsv_work*, *LAPACKE_sgtsv_work* and *LAPACKE_zgtsv_work*.

4.19.1972 LAPACKE_zgtsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgtsvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *dl,
                           const armpl_doublecomplex_t *d,
```

(continues on next page)

(continued from previous page)

```
                                const armpl_doublecomplex_t *du,
                                armpl_doublecomplex_t *dlf,
                                armpl_doublecomplex_t *df,
                                armpl_doublecomplex_t *duf,
                                armpl_doublecomplex_t *du2, armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *x, armpl_int_t ldx,
                                double *rcond, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgtsvx*, *LAPACKE_dgtsvx*, *LAPACKE_sgtsvx* and *LAPACKE_zgtsvx*. It also exists with a native Fortran interface as *zgtsvx*.

4.19.1973 LAPACKE_zgtsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgtsvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *dl,
                                const armpl_doublecomplex_t *d,
                                const armpl_doublecomplex_t *du,
                                armpl_doublecomplex_t *dlf,
                                armpl_doublecomplex_t *df,
                                armpl_doublecomplex_t *duf,
                                armpl_doublecomplex_t *du2, armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1974 LAPACKE_zgttrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgttrf(armpl_int_t n, armpl_doublecomplex_t *dl,
                           armpl_doublecomplex_t *d,
                           armpl_doublecomplex_t *du,
                           armpl_doublecomplex_t *du2, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrf*, *LAPACKE_dgttrf*, *LAPACKE_sgttrf* and *LAPACKE_zgttrf*. It also exists with a native Fortran interface as *zgttrf*.

4.19.1975 LAPACKE_zgttrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgttrf_work(armpl_int_t n, armpl_doublecomplex_t *dl,
                                armpl_doublecomplex_t *d,
                                armpl_doublecomplex_t *du,
                                armpl_doublecomplex_t *du2,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrf_work*, *LAPACKE_dgttrf_work*, *LAPACKE_sgttrf_work* and *LAPACKE_zgttrf_work*.

4.19.1976 LAPACKE_zgttrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgttrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *dl,
                           const armpl_doublecomplex_t *d,
                           const armpl_doublecomplex_t *du,
                           const armpl_doublecomplex_t *du2,
                           const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrs*, *LAPACKE_dgttrs*, *LAPACKE_sgttrs* and *LAPACKE_zgttrs*. It also exists with a native Fortran interface as *zgttrs*.

4.19.1977 LAPACKE_zgttrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zgttrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *dl,
                                const armpl_doublecomplex_t *d,
                                const armpl_doublecomplex_t *du,
                                const armpl_doublecomplex_t *du2,
                                const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgttrs_work*, *LAPACKE_dgttrs_work*, *LAPACKE_sgttrs_work* and *LAPACKE_zgttrs_work*.

4.19.1978 LAPACKE_zhbev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_int_t kd,
                          armpl_doublecomplex_t *ab, armpl_int_t ldab,
                          double *w, armpl_doublecomplex_t *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbev* and *LAPACKE_zhbev*. It also exists with a native Fortran interface as *zhbev*.

4.19.1979 LAPACKE_zhbev_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbev_2stage(armpl_int_t matrix_layout, char jobz,
                                 char uplo, armpl_int_t n, armpl_int_t kd,
                                 armpl_doublecomplex_t *ab, armpl_int_t ldab,
                                 double *w, armpl_doublecomplex_t *z,
                                 armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbev_2stage* and *LAPACKE_zhbev_2stage*. It also exists with a native Fortran interface as *zhbev_2stage*.

4.19.1980 LAPACKE_zhbev_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbev_2stage_work(armpl_int_t matrix_layout, char jobz,
                                      char uplo, armpl_int_t n,
                                      armpl_int_t kd,
                                      armpl_doublecomplex_t *ab,
                                      armpl_int_t ldab, double *w,
                                      armpl_doublecomplex_t *z,
                                      armpl_int_t ldz,
                                      armpl_doublecomplex_t *work,
                                      armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.1983 LAPACKE_zhbevd_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbevd_2stage(armpl_int_t matrix_layout, char jobz,
                                  char uplo, armpl_int_t n, armpl_int_t kd,
                                  armpl_doublecomplex_t *ab, armpl_int_t ldab,
                                  double *w, armpl_doublecomplex_t *z,
                                  armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbevd_2stage* and *LAPACKE_zhbevd_2stage*. It also exists with a native Fortran interface as *zhbevd_2stage*.

4.19.1984 LAPACKE_zhbevd_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbevd_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char uplo, armpl_int_t n,
                                       armpl_int_t kd,
                                       armpl_doublecomplex_t *ab,
                                       armpl_int_t ldab, double *w,
                                       armpl_doublecomplex_t *z,
                                       armpl_int_t ldz,
                                       armpl_doublecomplex_t *work,
                                       armpl_int_t lwork, double *rwork,
                                       armpl_int_t lrwork, armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.1985 LAPACKE_zhbevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                armpl_doublecomplex_t *ab, armpl_int_t ldab,
                                double *w, armpl_doublecomplex_t *z,
                                armpl_int_t ldz, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbevd_work* and *LAPACKE_zhbevd_work*.

4.19.1986 LAPACKE_zhbevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_int_t kd,
                           armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           armpl_doublecomplex_t *q, armpl_int_t ldq,
                           double vl, double vu, armpl_int_t il,
                           armpl_int_t iu, double abstol, armpl_int_t *m,
                           double *w, armpl_doublecomplex_t *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbevx* and *LAPACKE_zhbevx*. It also exists with a native Fortran interface as *zhbevx*.

4.19.1987 LAPACKE_zhbevx_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbevx_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  armpl_int_t kd, armpl_doublecomplex_t *ab,
                                  armpl_int_t ldab, armpl_doublecomplex_t *q,

                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbevx_work* and *LAPACKE_zhbevx_work*.

4.19.1990 LAPACKE_zhbgst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbgst(armpl_int_t matrix_layout, char vect, char uplo,
                           armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                           armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           const armpl_doublecomplex_t *bb, armpl_int_t ldbb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgst* and *LAPACKE_zhbgst*. It also exists with a native Fortran interface as *zhbgst*.

4.19.1991 LAPACKE_zhbgst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbgst_work(armpl_int_t matrix_layout, char vect,
                                char uplo, armpl_int_t n, armpl_int_t ka,
                                armpl_int_t kb, armpl_doublecomplex_t *ab,
                                armpl_int_t ldab,
                                const armpl_doublecomplex_t *bb,
                                armpl_int_t ldbb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgst_work* and *LAPACKE_zhbgst_work*.

4.19.1992 LAPACKE_zhbgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbgv(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                          armpl_doublecomplex_t *ab, armpl_int_t ldab,
                          armpl_doublecomplex_t *bb, armpl_int_t ldbb,
                          double *w, armpl_doublecomplex_t *z,
                          armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgv* and *LAPACKE_zhbgv*. It also exists with a native Fortran interface as *zhbgv*.

4.19.1993 LAPACKE_zhbgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbgv_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n, armpl_int_t ka,
                               armpl_int_t kb, armpl_doublecomplex_t *ab,
                               armpl_int_t ldab, armpl_doublecomplex_t *bb,
                               armpl_int_t ldbb, double *w,
                               armpl_doublecomplex_t *z, armpl_int_t ldz,
                               armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgv_work* and *LAPACKE_zhbgv_work*.

4.19.1994 LAPACKE_zhbgvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbgvd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_int_t ka, armpl_int_t kb,
                           armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           armpl_doublecomplex_t *bb, armpl_int_t ldbb,
                           double *w, armpl_doublecomplex_t *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgvd* and *LAPACKE_zhbgvd*. It also exists with a native Fortran interface as *zhbgvd*.

4.19.1995 LAPACKE_zhbgvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbgvd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n, armpl_int_t ka,
                                armpl_int_t kb, armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, armpl_doublecomplex_t *bb,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldbb, double *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgvd_work* and *LAPACKE_zhbgvd_work*.

4.19.1996 LAPACKE_zhbgvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbgvx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_int_t ka,
                           armpl_int_t kb, armpl_doublecomplex_t *ab,
                           armpl_int_t ldab, armpl_doublecomplex_t *bb,
                           armpl_int_t ldbb, armpl_doublecomplex_t *q,
                           armpl_int_t ldq, double vl, double vu,
                           armpl_int_t il, armpl_int_t iu, double abstol,
                           armpl_int_t *m, double *w,
                           armpl_doublecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgvx* and *LAPACKE_zhbgvx*. It also exists with a native Fortran interface as *zhbgvx*.

4.19.1997 LAPACKE_zhbgvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbgvx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_int_t ka, armpl_int_t kb,
                                armpl_doublecomplex_t *ab, armpl_int_t ldab,
                                armpl_doublecomplex_t *bb, armpl_int_t ldbb,
                                armpl_doublecomplex_t *q, armpl_int_t ldq,
                                double vl, double vu, armpl_int_t il,
                                armpl_int_t iu, double abstol, armpl_int_t *m,
                                double *w, armpl_doublecomplex_t *z,
                                armpl_int_t ldz, armpl_doublecomplex_t *work,
                                double *rwork, armpl_int_t *iwork,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbgvx_work* and *LAPACKE_zhbgvx_work*.

4.19.1998 LAPACKE_zhbtrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbtrd(armpl_int_t matrix_layout, char vect, char uplo,
                           armpl_int_t n, armpl_int_t kd,
                           armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           double *d, double *e, armpl_doublecomplex_t *q,
                           armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbtrd* and *LAPACKE_zhbtrd*. It also exists with a native Fortran interface as *zhbtrd*.

4.19.1999 LAPACKE_zhbtrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhbtrd_work(armpl_int_t matrix_layout, char vect,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                armpl_doublecomplex_t *ab, armpl_int_t ldab,
                                double *d, double *e,
                                armpl_doublecomplex_t *q, armpl_int_t ldq,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chbtrd_work* and *LAPACKE_zhbtrd_work*.

4.19.2000 LAPACKE_zhecon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhecon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, const armpl_int_t *ipiv,
                           double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_checon* and *LAPACKE_zhecon*. It also exists with a native Fortran interface as *zhecon*.

4.19.2001 LAPACKE_zhecon_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhecon_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, const armpl_doublecomplex_t *a,
                             armpl_int_t lda, const armpl_doublecomplex_t *e,
                             const armpl_int_t *ipiv, double anorm,
                             double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_checon_3* and *LAPACKE_zhecon_3*. It also exists with a native Fortran interface as *zhecon_3*.

4.19.2002 LAPACKE_zhecon_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhecon_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n,
                                  const armpl_doublecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_doublecomplex_t *e,
                                  const armpl_int_t *ipiv, double anorm,
                                  double *rcond,
                                  armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_checon_3_work* and *LAPACKE_zhecon_3_work*.

4.19.2003 LAPACKE_zhecon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhecon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                double anorm, double *rcond,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_checon_work* and *LAPACKE_zhecon_work*.

4.19.2004 LAPACKE_zheequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheequb(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, const armpl_doublecomplex_t *a,
                            armpl_int_t lda, double *s, double *scond,
                            double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2005 LAPACKE_zheequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheequb_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n,
                                 const armpl_doublecomplex_t *a,
                                 armpl_int_t lda, double *s, double *scond,
                                 double *amax, armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheequb_work* and *LAPACKE_zheequb_work*.

4.19.2006 LAPACKE_zheev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_doublecomplex_t *a,
                          armpl_int_t lda, double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheev* and *LAPACKE_zheev*. It also exists with a native Fortran interface as *zheev*.

4.19.2007 LAPACKE_zheev_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheev_2stage(armpl_int_t matrix_layout, char jobz,
                                 char uplo, armpl_int_t n,
                                 armpl_doublecomplex_t *a, armpl_int_t lda,
                                 double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheev_2stage* and *LAPACKE_zheev_2stage*. It also exists with a native Fortran interface as *zheev_2stage*.

4.19.2008 LAPACKE_zheev_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheev_2stage_work(armpl_int_t matrix_layout, char jobz,
                                      char uplo, armpl_int_t n,
                                      armpl_doublecomplex_t *a,
                                      armpl_int_t lda, double *w,
                                      armpl_doublecomplex_t *work,
                                      armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheev_2stage_work* and *LAPACKE_zheev_2stage_work*.

4.19.2009 LAPACKE_zheev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               double *w, armpl_doublecomplex_t *work,
                               armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheev_work* and *LAPACKE_zheev_work*.

4.19.2010 LAPACKE_zheevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevd* and *LAPACKE_zheevd*. It also exists with a native Fortran interface as *zheevd*.

4.19.2011 LAPACKE_zheevd_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevd_2stage(armpl_int_t matrix_layout, char jobz,
                                  char uplo, armpl_int_t n,
                                  armpl_doublecomplex_t *a, armpl_int_t lda,
                                  double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevd_2stage* and *LAPACKE_zheevd_2stage*. It also exists with a native Fortran interface as *zheevd_2stage*.

4.19.2012 LAPACKE_zheevd_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevd_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char uplo, armpl_int_t n,
                                       armpl_doublecomplex_t *a,
                                       armpl_int_t lda, double *w,
                                       armpl_doublecomplex_t *work,
                                       armpl_int_t lwork, double *rwork,
                                       armpl_int_t lrwork, armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevd_2stage_work* and *LAPACKE_zheevd_2stage_work*.

4.19.2013 LAPACKE_zheevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                double *w, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2014 LAPACKE_zheevr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevr(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, double vl, double vu,
                           armpl_int_t il, armpl_int_t iu, double abstol,
                           armpl_int_t *m, double *w,
                           armpl_doublecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevr* and *LAPACKE_zheevr*. It also exists with a native Fortran interface as *zheevr*.

4.19.2015 LAPACKE_zheevr_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevr_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  armpl_doublecomplex_t *a, armpl_int_t lda,
                                  double vl, double vu, armpl_int_t il,
                                  armpl_int_t iu, double abstol,
                                  armpl_int_t *m, double *w,
                                  armpl_doublecomplex_t *z, armpl_int_t ldz,
                                  armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevr_2stage* and *LAPACKE_zheevr_2stage*. It also exists with a native Fortran interface as *zheevr_2stage*.

4.19.2016 LAPACKE_zheevr_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevr_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       armpl_doublecomplex_t *a,
                                       armpl_int_t lda, double vl, double vu,
                                       armpl_int_t il, armpl_int_t iu,
                                       double abstol, armpl_int_t *m,
                                       double *w, armpl_doublecomplex_t *z,
                                       armpl_int_t ldz, armpl_int_t *isuppz,
                                       armpl_doublecomplex_t *work,
                                       armpl_int_t lwork, double *rwork,
                                       armpl_int_t lrwork, armpl_int_t *iwork,
                                       armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevr_2stage_work* and *LAPACKE_zheevr_2stage_work*.

4.19.2017 LAPACKE_zheevr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevr_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                double vl, double vu, armpl_int_t il,
                                armpl_int_t iu, double abstol, armpl_int_t *m,
                                double *w, armpl_doublecomplex_t *z,
                                armpl_int_t ldz, armpl_int_t *isuppz,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevr_work* and *LAPACKE_zheevr_work*.

4.19.2018 LAPACKE_zheevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, double vl, double vu,
                           armpl_int_t il, armpl_int_t iu, double abstol,
                           armpl_int_t *m, double *w,
                           armpl_doublecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevx* and *LAPACKE_zheevx*. It also exists with a native Fortran interface as *zheevx*.

4.19.2019 LAPACKE_zheevx_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevx_2stage(armpl_int_t matrix_layout, char jobz,
                                  char range, char uplo, armpl_int_t n,
                                  armpl_doublecomplex_t *a, armpl_int_t lda,
                                  double vl, double vu, armpl_int_t il,
                                  armpl_int_t iu, double abstol,
                                  armpl_int_t *m, double *w,
                                  armpl_doublecomplex_t *z, armpl_int_t ldz,
                                  armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevx_2stage* and *LAPACKE_zheevx_2stage*. It also exists with a native Fortran interface as *zheevx_2stage*.

4.19.2020 LAPACKE_zheevx_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevx_2stage_work(armpl_int_t matrix_layout, char jobz,
                                       char range, char uplo, armpl_int_t n,
                                       armpl_doublecomplex_t *a,
                                       armpl_int_t lda, double vl, double vu,
                                       armpl_int_t il, armpl_int_t iu,
                                       double abstol, armpl_int_t *m,
                                       double *w, armpl_doublecomplex_t *z,
                                       armpl_int_t ldz,
                                       armpl_doublecomplex_t *work,
                                       armpl_int_t lwork, double *rwork,
                                       armpl_int_t *iwork,
                                       armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevx_2stage_work* and *LAPACKE_zheevx_2stage_work*.

4.19.2021 LAPACKE_zheevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                double vl, double vu, armpl_int_t il,
                                armpl_int_t iu, double abstol, armpl_int_t *m,
                                double *w, armpl_doublecomplex_t *z,
                                armpl_int_t ldz, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheevx_work* and *LAPACKE_zheevx_work*.

4.19.2022 LAPACKE_zhegst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegst(armpl_int_t matrix_layout, armpl_int_t itype,
                           char uplo, armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, const armpl_doublecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegst* and *LAPACKE_zhegst*. It also exists with a native Fortran interface as *zhegst*.

4.19.2023 LAPACKE_zhegst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegst_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegst_work* and *LAPACKE_zhegst_work*.

4.19.2024 LAPACKE_zhegv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegv(armpl_int_t matrix_layout, armpl_int_t itype,
                          char jobz, char uplo, armpl_int_t n,
                          armpl_doublecomplex_t *a, armpl_int_t lda,
                          armpl_doublecomplex_t *b, armpl_int_t ldb,
                          double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegv* and *LAPACKE_zhegv*. It also exists with a native Fortran interface as *zhegv*.

4.19.2025 LAPACKE_zhegv_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegv_2stage(armpl_int_t matrix_layout, armpl_int_t itype,
                                 char jobz, char uplo, armpl_int_t n,
                                 armpl_doublecomplex_t *a, armpl_int_t lda,
                                 armpl_doublecomplex_t *b, armpl_int_t ldb,
                                 double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegv_2stage* and *LAPACKE_zhegv_2stage*. It also exists with a native Fortran interface as *zhegv_2stage*.

4.19.2026 LAPACKE_zhegv_2stage_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegv_2stage_work(armpl_int_t matrix_layout,
                                      armpl_int_t itype, char jobz, char uplo,
                                      armpl_int_t n, armpl_doublecomplex_t *a,
                                      armpl_int_t lda,
                                      armpl_doublecomplex_t *b,
                                      armpl_int_t ldb, double *w,
                                      armpl_doublecomplex_t *work,
                                      armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegv_2stage_work* and *LAPACKE_zhegv_2stage_work*.

4.19.2027 LAPACKE_zhegv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegv_work(armpl_int_t matrix_layout, armpl_int_t itype,
                               char jobz, char uplo, armpl_int_t n,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               armpl_doublecomplex_t *b, armpl_int_t ldb,
                               double *w, armpl_doublecomplex_t *work,
                               armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegv_work* and *LAPACKE_zhegv_work*.

4.19.2028 LAPACKE_zhegvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegvd(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char uplo, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           double *w);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegvd* and *LAPACKE_zhegvd*. It also exists with a native Fortran interface as *zhegvd*.

4.19.2029 LAPACKE_zhegvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegvd_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                double *w, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegvd_work* and *LAPACKE_zhegvd_work*.

4.19.2030 LAPACKE_zhegvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegvx(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char range, char uplo, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           double vl, double vu, armpl_int_t il,
                           armpl_int_t iu, double abstol, armpl_int_t *m,
                           double *w, armpl_doublecomplex_t *z,
                           armpl_int_t ldz, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegvx* and *LAPACKE_zhegvx*. It also exists with a native Fortran interface as *zhegvx*.

4.19.2031 LAPACKE_zhegvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhegvx_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char range, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, double vl, double vu,
                                armpl_int_t il, armpl_int_t iu, double abstol,
                                armpl_int_t *m, double *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chegvx_work* and *LAPACKE_zhegvx_work*.

4.19.2032 LAPACKE_zherfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zherfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *af, armpl_int_t ldaf,
                           const armpl_int_t *ipiv,
```

(continues on next page)

(continued from previous page)

```
                                const armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *x, armpl_int_t ldx,
                                double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cherfs* and *LAPACKE_zherfs*. It also exists with a native Fortran interface as *zherfs*.

4.19.2033 LAPACKE_zherfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zherfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *af,
                                armpl_int_t ldaf, const armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cherfs_work* and *LAPACKE_zherfs_work*.

4.19.2034 LAPACKE_zherfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zherfsx(armpl_int_t matrix_layout, char uplo, char equed,
                            armpl_int_t n, armpl_int_t nrhs,
                            const armpl_doublecomplex_t *a, armpl_int_t lda,
                            const armpl_doublecomplex_t *af, armpl_int_t ldaf,
                            const armpl_int_t *ipiv, const double *s,
                            const armpl_doublecomplex_t *b, armpl_int_t ldb,
                            armpl_doublecomplex_t *x, armpl_int_t ldx,
                            double *rcond, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cherfsx* and *LAPACKE_zherfsx*. It also exists with a native Fortran interface as *zherfsx*.

4.19.2035 LAPACKE_zherfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zherfsx_work(armpl_int_t matrix_layout, char uplo,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const armpl_doublecomplex_t *a,
                                 armpl_int_t lda,
                                 const armpl_doublecomplex_t *af,
                                 armpl_int_t ldaf, const armpl_int_t *ipiv,
                                 const double *s,
                                 const armpl_doublecomplex_t *b,
                                 armpl_int_t ldb, armpl_doublecomplex_t *x,
                                 armpl_int_t ldx, double *rcond, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cherfsx_work* and *LAPACKE_zherfsx_work*.

4.19.2036 LAPACKE_zhesv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_doublecomplex_t *a,
                          armpl_int_t lda, armpl_int_t *ipiv,
                          armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv* and *LAPACKE_zhesv*. It also exists with a native Fortran interface as *zhesv*.

4.19.2037 LAPACKE_zhesv_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesv_aa(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             armpl_doublecomplex_t *a, armpl_int_t lda,
                             armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                             armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_aa* and *LAPACKE_zhesv_aa*. It also exists with a native Fortran interface as *zhesv_aa*.

4.19.2038 LAPACKE_zhesv_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesv_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs,
                                    armpl_doublecomplex_t *a, armpl_int_t lda,
                                    armpl_doublecomplex_t *tb,
                                    armpl_int_t ltb, armpl_int_t *ipiv,
                                    armpl_int_t *ipiv2,
                                    armpl_doublecomplex_t *b,
                                    armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_aa_2stage* and *LAPACKE_zhesv_aa_2stage*. It also exists with a native Fortran interface as *zhesv_aa_2stage*.

4.19.2039 LAPACKE_zhesv_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesv_aa_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  armpl_doublecomplex_t *a, armpl_int_t lda,
                                  armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                                  armpl_int_t ldb,
                                  armpl_doublecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_aa_work* and *LAPACKE_zhesv_aa_work*.

4.19.2040 LAPACKE_zhesv_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesv_rk(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             armpl_doublecomplex_t *a, armpl_int_t lda,
                             armpl_doublecomplex_t *e, armpl_int_t *ipiv,
                             armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_rk* and *LAPACKE_zhesv_rk*. It also exists with a native Fortran interface as *zhesv_rk*.

4.19.2041 LAPACKE_zhesv_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesv_rk_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  armpl_doublecomplex_t *a, armpl_int_t lda,
                                  armpl_doublecomplex_t *e, armpl_int_t *ipiv,
                                  armpl_doublecomplex_t *b, armpl_int_t ldb,
                                  armpl_doublecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_rk_work* and *LAPACKE_zhesv_rk_work*.

4.19.2042 LAPACKE_zhesv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                               armpl_int_t ldb, armpl_doublecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesv_work* and *LAPACKE_zhesv_work*.

4.19.2043 LAPACKE_zhesvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, const armpl_doublecomplex_t *b,
                           armpl_int_t ldb, armpl_doublecomplex_t *x,
                           armpl_int_t ldx, double *rcond, double *ferr,
                           double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesvx* and *LAPACKE_zhesvx*. It also exists with a native Fortran interface as *zhesvx*.

4.19.2044 LAPACKE_zhesvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *af,
                                armpl_int_t ldaf, armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesvx_work* and *LAPACKE_zhesvx_work*.

4.19.2045 LAPACKE_zhesvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            armpl_doublecomplex_t *af, armpl_int_t ldaf,
                            armpl_int_t *ipiv, char *equed, double *s,
                            armpl_doublecomplex_t *b, armpl_int_t ldb,
                            armpl_doublecomplex_t *x, armpl_int_t ldx,
                            double *rcond, double *rpvgrw, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesvxx* and *LAPACKE_zhesvxx*. It also exists with a native Fortran interface as *zhesvxx*.

4.19.2046 LAPACKE_zhesvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhesvxx_work(armpl_int_t matrix_layout, char fact,
                                 char uplo, armpl_int_t n, armpl_int_t nrhs,
                                 armpl_doublecomplex_t *a, armpl_int_t lda,
                                 armpl_doublecomplex_t *af, armpl_int_t ldaf,
                                 armpl_int_t *ipiv, char *equed, double *s,
                                 armpl_doublecomplex_t *b, armpl_int_t ldb,
                                 armpl_doublecomplex_t *x, armpl_int_t ldx,
                                 double *rcond, double *rpvgrw, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chesvxx_work* and *LAPACKE_zhesvxx_work*.

4.19.2047 LAPACKE_zheswapr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheswapr(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_doublecomplex_t *a,
                             armpl_int_t lda, armpl_int_t i1,
                             armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheswapr* and *LAPACKE_zheswapr*. It also exists with a native Fortran interface as *zheswapr*.

4.19.2048 LAPACKE_zheswapr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zheswapr_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_doublecomplex_t *a,
                                  armpl_int_t lda, armpl_int_t i1,
                                  armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cheswapr_work* and *LAPACKE_zheswapr_work*.

4.19.2049 LAPACKE_zhetrd

4.19.2050 LAPACKE_zhetrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrd_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, double *d, double *e,
                                armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrd_work* and *LAPACKE_zhetrd_work*.

4.19.2051 LAPACKE_zhetrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf* and *LAPACKE_zhetrf*. It also exists with a native Fortran interface as *zhetrf*.

4.19.2052 LAPACKE_zhetrf_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrf_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_doublecomplex_t *a,
                              armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_aa* and *LAPACKE_zhetrf_aa*. It also exists with a native Fortran interface as *zhetrf_aa*.

4.19.2053 LAPACKE_zhetrf_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrf_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_doublecomplex_t *a,
                                     armpl_int_t lda,
                                     armpl_doublecomplex_t *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_aa_2stage* and *LAPACKE_zhetrf_aa_2stage*. It also exists with a native Fortran interface as *zhetrf_aa_2stage*.

4.19.2054 LAPACKE_zhetrf_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrf_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_doublecomplex_t *a,
                                   armpl_int_t lda, armpl_int_t *ipiv,
                                   armpl_doublecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_aa_work* and *LAPACKE_zhetrf_aa_work*.

4.19.2055 LAPACKE_zhetrf_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrf_rk(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_doublecomplex_t *a,
                              armpl_int_t lda, armpl_doublecomplex_t *e,
                              armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_rk* and *LAPACKE_zhetrf_rk*. It also exists with a native Fortran interface as *zhetrf_rk*.

4.19.2056 LAPACKE_zhetrf_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrf_rk_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_doublecomplex_t *a,
                                   armpl_int_t lda, armpl_doublecomplex_t *e,
                                   armpl_int_t *ipiv,
                                   armpl_doublecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_rk_work* and *LAPACKE_zhetrf_rk_work*.

4.19.2057 LAPACKE_zhetrf_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrf_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_rook* and *LAPACKE_zhetrf_rook*. It also exists with a native Fortran interface as *zhetrf_rook*.

4.19.2058 LAPACKE_zhetrf_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrf_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_doublecomplex_t *a,
                                     armpl_int_t lda, armpl_int_t *ipiv,
                                     armpl_doublecomplex_t *work,
                                     armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2059 LAPACKE_zhetrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrf_work* and *LAPACKE_zhetrf_work*.

4.19.2060 LAPACKE_zhetri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri* and *LAPACKE_zhetri*. It also exists with a native Fortran interface as *zhetri*.

4.19.2061 LAPACKE_zhetri2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetri2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_doublecomplex_t *a,
                            armpl_int_t lda, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri2* and *LAPACKE_zhetri2*. It also exists with a native Fortran interface as *zhetri2*.

4.19.2062 LAPACKE_zhetri2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetri2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, const armpl_int_t *ipiv,
                                 armpl_doublecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri2_work* and *LAPACKE_zhetri2_work*.

4.19.2063 LAPACKE_zhetri2x

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetri2x(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_doublecomplex_t *a,
                             armpl_int_t lda, const armpl_int_t *ipiv,
                             armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri2x* and *LAPACKE_zhetri2x*. It also exists with a native Fortran interface as *zhetri2x*.

4.19.2064 LAPACKE_zhetri2x_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetri2x_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_doublecomplex_t *a,
                                  armpl_int_t lda, const armpl_int_t *ipiv,
                                  armpl_doublecomplex_t *work,
                                  armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri2x_work* and *LAPACKE_zhetri2x_work*.

4.19.2065 LAPACKE_zhetri_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetri_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_doublecomplex_t *a,
                             armpl_int_t lda, const armpl_doublecomplex_t *e,
                             const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri_3* and *LAPACKE_zhetri_3*. It also exists with a native Fortran interface as *zhetri_3*.

4.19.2066 LAPACKE_zhetri_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetri_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_doublecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_doublecomplex_t *e,
                                  const armpl_int_t *ipiv,
                                  armpl_doublecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri_3_work* and *LAPACKE_zhetri_3_work*.

4.19.2067 LAPACKE_zhetri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetri_work* and *LAPACKE_zhetri_work*.

4.19.2068 LAPACKE_zhetrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs* and *LAPACKE_zhetrs*. It also exists with a native Fortran interface as *zhetrs*.

4.19.2069 LAPACKE_zhetrs2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_int_t nrhs,
                            const armpl_doublecomplex_t *a, armpl_int_t lda,
                            const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                            armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs2* and *LAPACKE_zhetrs2*. It also exists with a native Fortran interface as *zhetrs2*.

4.19.2070 LAPACKE_zhetrs2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_int_t nrhs,
                                 const armpl_doublecomplex_t *a,
                                 armpl_int_t lda, const armpl_int_t *ipiv,
                                 armpl_doublecomplex_t *b, armpl_int_t ldb,
                                 armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs2_work* and *LAPACKE_zhetrs2_work*.

4.19.2071 LAPACKE_zhetrs_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             const armpl_doublecomplex_t *a, armpl_int_t lda,
                             const armpl_doublecomplex_t *e,
                             const armpl_int_t *ipiv,
                             armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_3* and *LAPACKE_zhetrs_3*. It also exists with a native Fortran interface as *zhetrs_3*.

4.19.2072 LAPACKE_zhetrs_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  const armpl_doublecomplex_t *a,
                                  armpl_int_t lda,
```

(continues on next page)

(continued from previous page)

```
                                    const armpl_doublecomplex_t *e,
                                    const armpl_int_t *ipiv,
                                    armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_3_work* and *LAPACKE_zhetrs_3_work*.

4.19.2073 LAPACKE_zhetrs_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_int_t nrhs,
                              const armpl_doublecomplex_t *a, armpl_int_t lda,
                              const armpl_int_t *ipiv,
                              armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_aa* and *LAPACKE_zhetrs_aa*. It also exists with a native Fortran interface as *zhetrs_aa*.

4.19.2074 LAPACKE_zhetrs_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     armpl_doublecomplex_t *a,
                                     armpl_int_t lda,
                                     armpl_doublecomplex_t *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2,
                                     armpl_doublecomplex_t *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_aa_2stage* and *LAPACKE_zhetrs_aa_2stage*. It also exists with a native Fortran interface as *zhetrs_aa_2stage*.

4.19.2075 LAPACKE_zhetrs_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_int_t nrhs,
                                   const armpl_doublecomplex_t *a,
                                   armpl_int_t lda, const armpl_int_t *ipiv,
                                   armpl_doublecomplex_t *b, armpl_int_t ldb,
                                   armpl_doublecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_aa_work* and *LAPACKE_zhetrs_aa_work*.

4.19.2076 LAPACKE_zhetrs_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_rook* and *LAPACKE_zhetrs_rook*. It also exists with a native Fortran interface as *zhetrs_rook*.

4.19.2077 LAPACKE_zhetrs_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     const armpl_doublecomplex_t *a,
                                     armpl_int_t lda, const armpl_int_t *ipiv,
                                     armpl_doublecomplex_t *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_rook_work* and *LAPACKE_zhetrs_rook_work*.

4.19.2078 LAPACKE_zhetrs_work

```
#include "armpl.h"

armpl_int_t LAPACKE_zhetrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chetrs_work* and *LAPACKE_zhetrs_work*.

4.19.2079 LAPACKE_zhfrk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhfrk(armpl_int_t matrix_layout, char transr, char uplo,
                          char trans, armpl_int_t n, armpl_int_t k,
                          double alpha, const armpl_doublecomplex_t *a,
                          armpl_int_t lda, double beta,
                          armpl_doublecomplex_t *c);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chfrk* and *LAPACKE_zhfrk*. It also exists with a native Fortran interface as *zhfrk*.

4.19.2080 LAPACKE_zhfrk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhfrk_work(armpl_int_t matrix_layout, char transr,
                               char uplo, char trans, armpl_int_t n,
                               armpl_int_t k, double alpha,
                               const armpl_doublecomplex_t *a,
                               armpl_int_t lda, double beta,
                               armpl_doublecomplex_t *c);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chfrk_work* and *LAPACKE_zhfrk_work*.

4.19.2081 LAPACKE_zhgeqz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhgeqz(armpl_int_t matrix_layout, char job, char compq,
                           char compz, armpl_int_t n, armpl_int_t ilo,
                           armpl_int_t ihi, armpl_doublecomplex_t *h,
                           armpl_int_t ldh, armpl_doublecomplex_t *t,
                           armpl_int_t ldt, armpl_doublecomplex_t *alpha,
                           armpl_doublecomplex_t *beta,
                           armpl_doublecomplex_t *q, armpl_int_t ldq,
                           armpl_doublecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chgeqz*, *LAPACKE_dhgeqz*, *LAPACKE_shgeqz* and *LAPACKE_zhgeqz*. It also exists with a native Fortran interface as *zhgeqz*.

4.19.2082 LAPACKE_zhgeqz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhgeqz_work(armpl_int_t matrix_layout, char job,
                                char compq, char compz, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi,
                                armpl_doublecomplex_t *h, armpl_int_t ldh,
                                armpl_doublecomplex_t *t, armpl_int_t ldt,
                                armpl_doublecomplex_t *alpha,
                                armpl_doublecomplex_t *beta,
                                armpl_doublecomplex_t *q, armpl_int_t ldq,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chgeqz_work*, *LAPACKE_dhgeqz_work*, *LAPACKE_shgeqz_work* and *LAPACKE_zhgeqz_work*.

4.19.2083 LAPACKE_zhpcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *ap,
                           const armpl_int_t *ipiv, double anorm,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpcon* and *LAPACKE_zhpcon*. It also exists with a native Fortran interface as *zhpcon*.

4.19.2084 LAPACKE_zhpcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_doublecomplex_t *ap,
                                const armpl_int_t *ipiv, double anorm,
                                double *rcond, armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpcon_work* and *LAPACKE_zhpcon_work*.

4.19.2085 LAPACKE_zhpev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpev(armpl_int_t matrix_layout, char jobz, char uplo,
                          armpl_int_t n, armpl_doublecomplex_t *ap, double *w,
                          armpl_doublecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpev* and *LAPACKE_zhpev*. It also exists with a native Fortran interface as *zhpev*.

4.19.2086 LAPACKE_zhpev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpev_work(armpl_int_t matrix_layout, char jobz,
                               char uplo, armpl_int_t n,
                               armpl_doublecomplex_t *ap, double *w,
                               armpl_doublecomplex_t *z, armpl_int_t ldz,
                               armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpev_work* and *LAPACKE_zhpev_work*.

4.19.2087 LAPACKE_zhpevd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpevd(armpl_int_t matrix_layout, char jobz, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *ap,
                           double *w, armpl_doublecomplex_t *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpevd* and *LAPACKE_zhpevd*. It also exists with a native Fortran interface as *zhpevd*.

4.19.2088 LAPACKE_zhpevd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpevd_work(armpl_int_t matrix_layout, char jobz,
                                char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *ap, double *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpevd_work* and *LAPACKE_zhpevd_work*.

4.19.2089 LAPACKE_zhpevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpevx(armpl_int_t matrix_layout, char jobz, char range,
                           char uplo, armpl_int_t n,
```

(continues on next page)

(continued from previous page)

```
                                armpl_doublecomplex_t *ap, double vl, double vu,
                                armpl_int_t il, armpl_int_t iu, double abstol,
                                armpl_int_t *m, double *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpevx* and *LAPACKE_zhpevx*. It also exists with a native Fortran interface as *zhpevx*.

4.19.2090 LAPACKE_zhpevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpevx_work(armpl_int_t matrix_layout, char jobz,
                                char range, char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *ap, double vl,
                                double vu, armpl_int_t il, armpl_int_t iu,
                                double abstol, armpl_int_t *m, double *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_doublecomplex_t *work, double *rwork,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpevx_work* and *LAPACKE_zhpevx_work*.

4.19.2091 LAPACKE_zhpgst

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpgst(armpl_int_t matrix_layout, armpl_int_t itype,
                           char uplo, armpl_int_t n,
                           armpl_doublecomplex_t *ap,
                           const armpl_doublecomplex_t *bp);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgst* and *LAPACKE_zhpgst*. It also exists with a native Fortran interface as *zhpgst*.

4.19.2092 LAPACKE_zhpgst_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpgst_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *ap,
                                const armpl_doublecomplex_t *bp);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgst_work* and *LAPACKE_zhpgst_work*.

4.19.2093 LAPACKE_zhpgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpgv(armpl_int_t matrix_layout, armpl_int_t itype,
                          char jobz, char uplo, armpl_int_t n,
                          armpl_doublecomplex_t *ap,
                          armpl_doublecomplex_t *bp, double *w,
                          armpl_doublecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgv* and *LAPACKE_zhpgv*. It also exists with a native Fortran interface as *zhpgv*.

4.19.2094 LAPACKE_zhpgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpgv_work(armpl_int_t matrix_layout, armpl_int_t itype,
                               char jobz, char uplo, armpl_int_t n,
                               armpl_doublecomplex_t *ap,
                               armpl_doublecomplex_t *bp, double *w,
                               armpl_doublecomplex_t *z, armpl_int_t ldz,
                               armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgv_work* and *LAPACKE_zhpgv_work*.

4.19.2095 LAPACKE_zhpgvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpgvd(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char uplo, armpl_int_t n,
                           armpl_doublecomplex_t *ap,
                           armpl_doublecomplex_t *bp, double *w,
                           armpl_doublecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgvd* and *LAPACKE_zhpgvd*. It also exists with a native Fortran interface as *zhpgvd*.

4.19.2096 LAPACKE_zhpgvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpgvd_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *ap,
                                armpl_doublecomplex_t *bp, double *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgvd_work* and *LAPACKE_zhpgvd_work*.

4.19.2097 LAPACKE_zhpgvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpgvx(armpl_int_t matrix_layout, armpl_int_t itype,
                           char jobz, char range, char uplo, armpl_int_t n,
                           armpl_doublecomplex_t *ap,
                           armpl_doublecomplex_t *bp, double vl, double vu,
                           armpl_int_t il, armpl_int_t iu, double abstol,
                           armpl_int_t *m, double *w,
                           armpl_doublecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgvx* and *LAPACKE_zhpgvx*. It also exists with a native Fortran interface as *zhpgvx*.

4.19.2098 LAPACKE_zhpgvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpgvx_work(armpl_int_t matrix_layout, armpl_int_t itype,
                                char jobz, char range, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *ap,
                                armpl_doublecomplex_t *bp, double vl,
                                double vu, armpl_int_t il, armpl_int_t iu,
                                double abstol, armpl_int_t *m, double *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_doublecomplex_t *work, double *rwork,
                                armpl_int_t *iwork, armpl_int_t *ifail);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpgvx_work* and *LAPACKE_zhpgvx_work*.

4.19.2099 LAPACKE_zhprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           const armpl_doublecomplex_t *afp,
                           const armpl_int_t *ipiv,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chprfs* and *LAPACKE_zhprfs*. It also exists with a native Fortran interface as *zhprfs*.

4.19.2100 LAPACKE_zhprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                const armpl_doublecomplex_t *afp,
                                const armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chprfs_work* and *LAPACKE_zhprfs_work*.

4.19.2101 LAPACKE_zhpsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_doublecomplex_t *ap,
                          armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpsv* and *LAPACKE_zhpsv*. It also exists with a native Fortran interface as *zhpsv*.

4.19.2102 LAPACKE_zhpsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_doublecomplex_t *ap, armpl_int_t *ipiv,
                               armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpsv_work* and *LAPACKE_zhpsv_work*.

4.19.2103 LAPACKE_zhpsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           armpl_doublecomplex_t *afp, armpl_int_t *ipiv,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *rcond, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpsvx* and *LAPACKE_zhpsvx*. It also exists with a native Fortran interface as *zhpsvx*.

4.19.2104 LAPACKE_zhpsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhpsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                armpl_doublecomplex_t *afp, armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chpsvx_work* and *LAPACKE_zhpsvx_work*.

4.19.2105 LAPACKE_zhptrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhptrd(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *ap,
                           double *d, double *e, armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrd* and *LAPACKE_zhptrd*. It also exists with a native Fortran interface as *zhptrd*.

4.19.2106 LAPACKE_zhptrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhptrd_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *ap,
                                double *d, double *e,
                                armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrd_work* and *LAPACKE_zhptrd_work*.

4.19.2107 LAPACKE_zhptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *ap,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrf* and *LAPACKE_zhptrf*. It also exists with a native Fortran interface as *zhptrf*.

4.19.2108 LAPACKE_zhptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *ap,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrf_work* and *LAPACKE_zhptrf_work*.

4.19.2109 LAPACKE_zhptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *ap,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptri* and *LAPACKE_zhptri*. It also exists with a native Fortran interface as *zhptri*.

4.19.2110 LAPACKE_zhptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *ap,
                                const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptri_work* and *LAPACKE_zhptri_work*.

4.19.2111 LAPACKE_zhptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2112 LAPACKE_zhptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chptrs_work* and *LAPACKE_zhptrs_work*.

4.19.2113 LAPACKE_zhsein

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhsein(armpl_int_t matrix_layout, char job, char eigsrc,
                           char initv, const armpl_int_t *select,
                           armpl_int_t n, const armpl_doublecomplex_t *h,
                           armpl_int_t ldh, armpl_doublecomplex_t *w,
                           armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                           armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t mm, armpl_int_t *m,
                           armpl_int_t *ifaill, armpl_int_t *ifailr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chsein*, *LAPACKE_dhsein*, *LAPACKE_shsein* and *LAPACKE_zhsein*. It also exists with a native Fortran interface as *zhsein*.

4.19.2114 LAPACKE_zhsein_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhsein_work(armpl_int_t matrix_layout, char job,
                                char eigsrc, char initv,
                                const armpl_int_t *select, armpl_int_t n,
                                const armpl_doublecomplex_t *h,
                                armpl_int_t ldh, armpl_doublecomplex_t *w,
                                armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                                armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                                armpl_int_t mm, armpl_int_t *m,
                                armpl_doublecomplex_t *work, double *rwork,
                                armpl_int_t *ifaill, armpl_int_t *ifailr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2115 LAPACKE_zhseqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhseqr(armpl_int_t matrix_layout, char job, char compz,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           armpl_doublecomplex_t *h, armpl_int_t ldh,
                           armpl_doublecomplex_t *w, armpl_doublecomplex_t *z,
                           armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chseqr*, *LAPACKE_dhseqr*, *LAPACKE_shseqr* and *LAPACKE_zhseqr*. It also exists with a native Fortran interface as *zhseqr*.

4.19.2116 LAPACKE_zhseqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zhseqr_work(armpl_int_t matrix_layout, char job,
                                char compz, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, armpl_doublecomplex_t *h,
                                armpl_int_t ldh, armpl_doublecomplex_t *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_chseqr_work*, *LAPACKE_dhseqr_work*, *LAPACKE_shseqr_work* and *LAPACKE_zhseqr_work*.

4.19.2117 LAPACKE_zlacgv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacgv(armpl_int_t n, armpl_doublecomplex_t *x,
                           armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacgv* and *LAPACKE_zlacgv*. It also exists with a native Fortran interface as *zlacgv*.

4.19.2118 LAPACKE_zlacgv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacgv_work(armpl_int_t n, armpl_doublecomplex_t *x,
                                armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacgv_work* and *LAPACKE_zlacgv_work*.

4.19.2119 LAPACKE_zlacn2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacn2(armpl_int_t n, armpl_doublecomplex_t *v,
                           armpl_doublecomplex_t *x, double *est,
                           armpl_int_t *kase, armpl_int_t *isave);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacn2*, *LAPACKE_dlacn2*, *LAPACKE_slacn2* and *LAPACKE_zlacn2*. It also exists with a native Fortran interface as *zlacn2*.

4.19.2120 LAPACKE_zlacn2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacn2_work(armpl_int_t n, armpl_doublecomplex_t *v,
                                armpl_doublecomplex_t *x, double *est,
                                armpl_int_t *kase, armpl_int_t *isave);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacn2_work*, *LAPACKE_dlacn2_work*, *LAPACKE_slacn2_work* and *LAPACKE_zlacn2_work*.

4.19.2121 LAPACKE_zlacp2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacp2(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n, const double *a,
                           armpl_int_t lda, armpl_doublecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacp2* and *LAPACKE_zlacp2*. It also exists with a native Fortran interface as *zlacp2*.

4.19.2122 LAPACKE_zlacp2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacp2_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n, const double *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacp2_work* and *LAPACKE_zlacp2_work*.

4.19.2123 LAPACKE_zlacpy

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacpy(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacpy*, *LAPACKE_dlacpy*, *LAPACKE_slacpy* and *LAPACKE_zlacpy*. It also exists with a native Fortran interface as *zlacpy*.

4.19.2124 LAPACKE_zlacpy_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacpy_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacpy_work*, *LAPACKE_dlacpy_work*, *LAPACKE_slacpy_work* and *LAPACKE_zlacpy_work*.

4.19.2125 LAPACKE_zlacrm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacrm(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, const double *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacrm* and *LAPACKE_zlacrm*. It also exists with a native Fortran interface as *zlacrm*.

4.19.2126 LAPACKE_zlacrm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlacrm_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda, const double *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *c,
                                armpl_int_t ldc, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clacrm_work* and *LAPACKE_zlacrm_work*.

4.19.2127 LAPACKE_zlag2c

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlag2c(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *sa,
                           armpl_int_t ldsa);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_zlag2c*. It also exists with a native Fortran interface as *zlag2c*.

4.19.2128 LAPACKE_zlag2c_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlag2c_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *sa,
                                armpl_int_t ldsa);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2141 LAPACKE_zlantr

Syntax

```
#include "armpl.h"

double LAPACKE_zlantr(armpl_int_t matrix_layout, char norm, char uplo,
                      char diag, armpl_int_t m, armpl_int_t n,
                      const armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clantr*, *LAPACKE_dlantr*, *LAPACKE_slantr* and *LAPACKE_zlantr*. It also exists with a native Fortran interface as *zlantr*.

4.19.2142 LAPACKE_zlantr_work

Syntax

```
#include "armpl.h"

double LAPACKE_zlantr_work(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t m, armpl_int_t n,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2144 LAPACKE_zlapmr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlapmr_work(armpl_int_t matrix_layout, armpl_int_t forwrd,
                                armpl_int_t m, armpl_int_t n,
                                armpl_doublecomplex_t *x, armpl_int_t ldx,
                                armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2145 LAPACKE_zlapmt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlapmt(armpl_int_t matrix_layout, armpl_int_t forwrd,
                           armpl_int_t m, armpl_int_t n,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmt*, *LAPACKE_dlapmt*, *LAPACKE_slapmt* and *LAPACKE_zlapmt*. It also exists with a native Fortran interface as *zlapmt*.

4.19.2146 LAPACKE_zlapmt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlapmt_work(armpl_int_t matrix_layout, armpl_int_t forwrd,
                                armpl_int_t m, armpl_int_t n,
                                armpl_doublecomplex_t *x, armpl_int_t ldx,
                                armpl_int_t *k);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clapmt_work*, *LAPACKE_dlapmt_work*, *LAPACKE_slapmt_work* and *LAPACKE_zlapmt_work*.

4.19.2147 LAPACKE_zlarcm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarcm(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const double *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarcm* and *LAPACKE_zlarcm*. It also exists with a native Fortran interface as *zlarcm*.

4.19.2148 LAPACKE_zlarcm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarcm_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const double *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *c,
                                armpl_int_t ldc, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarcm_work* and *LAPACKE_zlarcm_work*.

4.19.2149 LAPACKE_zlarfb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarfb(armpl_int_t matrix_layout, char side, char trans,
                           char direct, char storev, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           const armpl_doublecomplex_t *v, armpl_int_t ldv,
                           const armpl_doublecomplex_t *t, armpl_int_t ldt,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfb*, *LAPACKE_dlarfb*, *LAPACKE_slarfb* and *LAPACKE_zlarfb*. It also exists with a native Fortran interface as *zlarfb*.

4.19.2150 LAPACKE_zlarfb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarfb_work(armpl_int_t matrix_layout, char side,
                                char trans, char direct, char storev,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                const armpl_doublecomplex_t *v,
                                armpl_int_t ldv,
                                const armpl_doublecomplex_t *t,
                                armpl_int_t ldt, armpl_doublecomplex_t *c,
                                armpl_int_t ldc, armpl_doublecomplex_t *work,
                                armpl_int_t ldwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfb_work*, *LAPACKE_dlarfb_work*, *LAPACKE_slarfb_work* and *LAPACKE_zlarfb_work*.

4.19.2151 LAPACKE_zlarfg

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarfg(armpl_int_t n, armpl_doublecomplex_t *alpha,
                           armpl_doublecomplex_t *x, armpl_int_t incx,
                           armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfg*, *LAPACKE_dlarfg*, *LAPACKE_slarfg* and *LAPACKE_zlarfg*. It also exists with a native Fortran interface as *zlarfg*.

4.19.2152 LAPACKE_zlarfg_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarfg_work(armpl_int_t n, armpl_doublecomplex_t *alpha,
                                armpl_doublecomplex_t *x, armpl_int_t incx,
                                armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfg_work*, *LAPACKE_dlarfg_work*, *LAPACKE_slarfg_work* and *LAPACKE_zlarfg_work*.

4.19.2153 LAPACKE_zlarft

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarft(armpl_int_t matrix_layout, char direct,
                           char storev, armpl_int_t n, armpl_int_t k,
                           const armpl_doublecomplex_t *v, armpl_int_t ldv,
                           const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarft*, *LAPACKE_dlarft*, *LAPACKE_slarft* and *LAPACKE_zlarft*. It also exists with a native Fortran interface as *zlarft*.

4.19.2154 LAPACKE_zlarft_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarft_work(armpl_int_t matrix_layout, char direct,
                                char storev, armpl_int_t n, armpl_int_t k,
                                const armpl_doublecomplex_t *v,
                                armpl_int_t ldv,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarft_work*, *LAPACKE_dlarft_work*, *LAPACKE_slarft_work* and *LAPACKE_zlarft_work*.

4.19.2155 LAPACKE_zlarfx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarfx(armpl_int_t matrix_layout, char side,
                           armpl_int_t m, armpl_int_t n,
                           const armpl_doublecomplex_t *v,
                           armpl_doublecomplex_t tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc,
                           armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfx*, *LAPACKE_dlarfx*, *LAPACKE_slarfx* and *LAPACKE_zlarfx*. It also exists with a native Fortran interface as *zlarfx*.

4.19.2156 LAPACKE_zlarfx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarfx_work(armpl_int_t matrix_layout, char side,
                                armpl_int_t m, armpl_int_t n,
                                const armpl_doublecomplex_t *v,
                                armpl_doublecomplex_t tau,
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarfx_work*, *LAPACKE_dlarfx_work*, *LAPACKE_slarfx_work* and *LAPACKE_zlarfx_work*.

4.19.2157 LAPACKE_zlarnv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarnv(armpl_int_t idist, armpl_int_t *iseed,
                           armpl_int_t n, armpl_doublecomplex_t *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarnv*, *LAPACKE_dlarnv*, *LAPACKE_slarnv* and *LAPACKE_zlarnv*. It also exists with a native Fortran interface as *zlarnv*.

4.19.2158 LAPACKE_zlarnv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlarnv_work(armpl_int_t idist, armpl_int_t *iseed,
                                armpl_int_t n, armpl_doublecomplex_t *x);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clarnv_work*, *LAPACKE_dlarnv_work*, *LAPACKE_slarnv_work* and *LAPACKE_zlarnv_work*.

4.19.2159 LAPACKE_zlascl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlascl(armpl_int_t matrix_layout, char type,
                           armpl_int_t kl, armpl_int_t ku, double cfrom,
                           double cto, armpl_int_t m, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clascl*, *LAPACKE_dlascl*, *LAPACKE_slascl* and *LAPACKE_zlascl*. It also exists with a native Fortran interface as *zlascl*.

4.19.2160 LAPACKE_zlascl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlascl_work(armpl_int_t matrix_layout, char type,
                                armpl_int_t kl, armpl_int_t ku, double cfrom,
                                double cto, armpl_int_t m, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_clascl_work*, *LAPACKE_dlascl_work*, *LAPACKE_slascl_work* and *LAPACKE_zlascl_work*.

4.19.2161 LAPACKE_zlaset

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlaset(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t m, armpl_int_t n,
                           armpl_doublecomplex_t alpha,
                           armpl_doublecomplex_t beta,
                           armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claset*, *LAPACKE_dlaset*, *LAPACKE_slaset* and *LAPACKE_zlaset*. It also exists with a native Fortran interface as *zlaset*.

4.19.2162 LAPACKE_zlaset_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlaset_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t m, armpl_int_t n,
                                armpl_doublecomplex_t alpha,
                                armpl_doublecomplex_t beta,
                                armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claset_work*, *LAPACKE_dlaset_work*, *LAPACKE_slaset_work* and *LAPACKE_zlaset_work*.

4.19.2163 LAPACKE_zlassq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlassq(armpl_int_t n, armpl_doublecomplex_t *x,
                           armpl_int_t incx, double *scale, double *sumsq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_classq*, *LAPACKE_dlassq*, *LAPACKE_slassq* and *LAPACKE_zlassq*. It also exists with a native Fortran interface as *zlassq*.

4.19.2164 LAPACKE_zlassq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlassq_work(armpl_int_t n, armpl_doublecomplex_t *x,
                                armpl_int_t incx, double *scale,
                                double *sumsq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_classq_work*, *LAPACKE_dlassq_work*, *LAPACKE_slassq_work* and *LAPACKE_zlassq_work*.

4.19.2165 LAPACKE_zlaswp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlaswp(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_int_t k1, armpl_int_t k2,
                           const armpl_int_t *ipiv, armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_claswp*, *LAPACKE_dlaswp*, *LAPACKE_slaswp* and *LAPACKE_zlaswp*. It also exists with a native Fortran interface as *zlaswp*.

4.19.2166 LAPACKE_zlaswp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlaswp_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_int_t k1, armpl_int_t k2,
                                const armpl_int_t *ipiv, armpl_int_t incx);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2167 LAPACKE_zlatms

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.2168 LAPACKE_zlatms_work

Syntax

Routine is deprecated. Please choose a suitable alternative.

4.19.2169 LAPACKE_zlauum

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zlauum(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2171 LAPACKE_zpbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd,
                           const armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbcon*, *LAPACKE_dpbcon*, *LAPACKE_spbcon* and *LAPACKE_zpbcon*. It also exists with a native Fortran interface as *zpbcon*.

4.19.2172 LAPACKE_zpbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, double anorm, double *rcond,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbcon_work*, *LAPACKE_dpbcon_work*, *LAPACKE_spbcon_work* and *LAPACKE_zpbcon_work*.

4.19.2173 LAPACKE_zpbequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbequ(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd,
                           const armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           double *s, double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbequ*, *LAPACKE_dpbequ*, *LAPACKE_spbequ* and *LAPACKE_zpbequ*. It also exists with a native Fortran interface as *zpbequ*.

4.19.2174 LAPACKE_zpbequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbequ_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, double *s, double *scond,
                                double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbequ_work*, *LAPACKE_dpbequ_work*, *LAPACKE_spbequ_work* and *LAPACKE_zpbequ_work*.

4.19.2175 LAPACKE_zpbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           const armpl_doublecomplex_t *afb,
                           armpl_int_t ldafb, const armpl_doublecomplex_t *b,
                           armpl_int_t ldb, armpl_doublecomplex_t *x,
                           armpl_int_t ldx, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbrfs*, *LAPACKE_dpbrfs*, *LAPACKE_spbrfs* and *LAPACKE_zpbrfs*. It also exists with a native Fortran interface as *zpbrfs*.

4.19.2176 LAPACKE_zpbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab,
                                const armpl_doublecomplex_t *afb,
                                armpl_int_t ldafb,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbrfs_work*, *LAPACKE_dpbrfs_work*, *LAPACKE_spbrfs_work* and *LAPACKE_zpbrfs_work*.

4.19.2177 LAPACKE_zpbstf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbstf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kb,
                           armpl_doublecomplex_t *bb, armpl_int_t ldbb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbstf*, *LAPACKE_dpbstf*, *LAPACKE_spbstf* and *LAPACKE_zpbstf*. It also exists with a native Fortran interface as *zpbstf*.

4.19.2178 LAPACKE_zpbstf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbstf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kb,
                                armpl_doublecomplex_t *bb, armpl_int_t ldbb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbstf_work*, *LAPACKE_dpbstf_work*, *LAPACKE_spbstf_work* and *LAPACKE_zpbstf_work*.

4.19.2179 LAPACKE_zpbsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t kd, armpl_int_t nrhs,
                          armpl_doublecomplex_t *ab, armpl_int_t ldab,
                          armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsv*, *LAPACKE_dpbsv*, *LAPACKE_spbsv* and *LAPACKE_zpbsv*. It also exists with a native Fortran interface as *zpbsv*.

4.19.2180 LAPACKE_zpbsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t kd,
                               armpl_int_t nrhs, armpl_doublecomplex_t *ab,
                               armpl_int_t ldab, armpl_doublecomplex_t *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsv_work*, *LAPACKE_dpbsv_work*, *LAPACKE_spbsv_work* and *LAPACKE_zpbsv_work*.

4.19.2181 LAPACKE_zpbsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           armpl_doublecomplex_t *afb, armpl_int_t ldafb,
                           char *equed, double *s, armpl_doublecomplex_t *b,
                           armpl_int_t ldb, armpl_doublecomplex_t *x,
                           armpl_int_t ldx, double *rcond, double *ferr,
                           double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbsvx*, *LAPACKE_dpbsvx*, *LAPACKE_spbsvx* and *LAPACKE_zpbsvx*. It also exists with a native Fortran interface as *zpbsvx*.

4.19.2182 LAPACKE_zpbsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs, armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, armpl_doublecomplex_t *afb,
                                armpl_int_t ldafb, char *equed, double *s,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *x, armpl_int_t ldx,
```

(continues on next page)

(continued from previous page)

```
                                double *rcond, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2183 LAPACKE_zpbtrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbtrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd,
                           armpl_doublecomplex_t *ab, armpl_int_t ldab);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrf*, *LAPACKE_dpbtrf*, *LAPACKE_spbtrf* and *LAPACKE_zpbtrf*. It also exists with a native Fortran interface as *zpbtrf*.

4.19.2184 LAPACKE_zpbtrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbtrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_doublecomplex_t *ab, armpl_int_t ldab);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrf_work*, *LAPACKE_dpbtrf_work*, *LAPACKE_spbtrf_work* and *LAPACKE_zpbtrf_work*.

4.19.2185 LAPACKE_zpbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbtrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t kd, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrs*, *LAPACKE_dpbtrs*, *LAPACKE_spbtrs* and *LAPACKE_zpbtrs*. It also exists with a native Fortran interface as *zpbtrs*.

4.19.2186 LAPACKE_zpbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpbtrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t kd,
                                armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, armpl_doublecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpbtrs_work*, *LAPACKE_dpbtrs_work*, *LAPACKE_spbtrs_work* and *LAPACKE_zpbtrs_work*.

4.19.2187 LAPACKE_zpftrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpftrf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrf*, *LAPACKE_dpftrf*, *LAPACKE_spftrf* and *LAPACKE_zpftrf*. It also exists with a native Fortran interface as *zpftrf*.

4.19.2188 LAPACKE_zpftrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpftrf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrf_work*, *LAPACKE_dpftrf_work*, *LAPACKE_spftrf_work* and *LAPACKE_zpftrf_work*.

4.19.2189 LAPACKE_zpftri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpftri(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftri*, *LAPACKE_dpftri*, *LAPACKE_spftri* and *LAPACKE_zpftri*. It also exists with a native Fortran interface as *zpftri*.

4.19.2190 LAPACKE_zpftri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpftri_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                armpl_doublecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2191 LAPACKE_zpftrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpftrs(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a,
                           armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrs*, *LAPACKE_dpftrs*, *LAPACKE_spftrs* and *LAPACKE_zpftrs*. It also exists with a native Fortran interface as *zpftrs*.

4.19.2192 LAPACKE_zpftrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpftrs_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpftrs_work*, *LAPACKE_dpftrs_work*, *LAPACKE_spftrs_work* and *LAPACKE_zpftrs_work*.

4.19.2193 LAPACKE_zpocon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpocon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2194 LAPACKE_zpocon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpocon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda, double anorm, double *rcond,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpocon_work*, *LAPACKE_dpocon_work*, *LAPACKE_spocon_work* and *LAPACKE_zpocon_work*.

4.19.2195 LAPACKE_zpoequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpoequ(armpl_int_t matrix_layout, armpl_int_t n,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           double *s, double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequ*, *LAPACKE_dpoequ*, *LAPACKE_spoequ* and *LAPACKE_zpoequ*. It also exists with a native Fortran interface as *zpoequ*.

4.19.2196 LAPACKE_zpoequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpoequ_work(armpl_int_t matrix_layout, armpl_int_t n,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, double *s, double *scond,
                                double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequ_work*, *LAPACKE_dpoequ_work*, *LAPACKE_spoequ_work* and *LAPACKE_zpoequ_work*.

4.19.2197 LAPACKE_zpoequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpoequb(armpl_int_t matrix_layout, armpl_int_t n,
                            const armpl_doublecomplex_t *a, armpl_int_t lda,
                            double *s, double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequb*, *LAPACKE_dpoequb*, *LAPACKE_spoequb* and *LAPACKE_zpoequb*. It also exists with a native Fortran interface as *zpoequb*.

4.19.2198 LAPACKE_zpoequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpoequb_work(armpl_int_t matrix_layout, armpl_int_t n,
                                 const armpl_doublecomplex_t *a,
                                 armpl_int_t lda, double *s, double *scond,
                                 double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpoequb_work*, *LAPACKE_dpoequb_work*, *LAPACKE_spoequb_work* and *LAPACKE_zpoequb_work*.

4.19.2199 LAPACKE_zporfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zporfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *af, armpl_int_t ldaf,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfs*, *LAPACKE_dporfs*, *LAPACKE_sporfs* and *LAPACKE_zporfs*. It also exists with a native Fortran interface as *zporfs*.

4.19.2200 LAPACKE_zporfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zporfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *af,
                                armpl_int_t ldaf,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfs_work*, *LAPACKE_dporfs_work*, *LAPACKE_sporfs_work* and *LAPACKE_zporfs_work*.

4.19.2201 LAPACKE_zporfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zporfsx(armpl_int_t matrix_layout, char uplo, char equed,
                            armpl_int_t n, armpl_int_t nrhs,
                            const armpl_doublecomplex_t *a, armpl_int_t lda,
                            const armpl_doublecomplex_t *af, armpl_int_t ldaf,
                            const double *s, const armpl_doublecomplex_t *b,
                            armpl_int_t ldb, armpl_doublecomplex_t *x,
                            armpl_int_t ldx, double *rcond, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfsx*, *LAPACKE_dporfsx*, *LAPACKE_sporfsx* and *LAPACKE_zporfsx*. It also exists with a native Fortran interface as *zporfsx*.

4.19.2202 LAPACKE_zporfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zporfsx_work(armpl_int_t matrix_layout, char uplo,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const armpl_doublecomplex_t *a,
                                 armpl_int_t lda,
                                 const armpl_doublecomplex_t *af,
                                 armpl_int_t ldaf, const double *s,
                                 const armpl_doublecomplex_t *b,
                                 armpl_int_t ldb, armpl_doublecomplex_t *x,
                                 armpl_int_t ldx, double *rcond, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cporfsx_work*, *LAPACKE_dporfsx_work*, *LAPACKE_sporfsx_work* and *LAPACKE_zporfsx_work*.

4.19.2203 LAPACKE_zposv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zposv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_doublecomplex_t *a,
                          armpl_int_t lda, armpl_doublecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposv*, *LAPACKE_dposv*, *LAPACKE_sposv* and *LAPACKE_zposv*. It also exists with a native Fortran interface as *zposv*.

4.19.2204 LAPACKE_zposv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zposv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposv_work*, *LAPACKE_dposv_work*, *LAPACKE_sposv_work* and *LAPACKE_zposv_work*.

4.19.2205 LAPACKE_zposvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zposvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *af, armpl_int_t ldaf,
                           char *equed, double *s, armpl_doublecomplex_t *b,
                           armpl_int_t ldb, armpl_doublecomplex_t *x,
                           armpl_int_t ldx, double *rcond, double *ferr,
                           double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cposvx*, *LAPACKE_dposvx*, *LAPACKE_sposvx* and *LAPACKE_zposvx*. It also exists with a native Fortran interface as *zposvx*.

4.19.2206 LAPACKE_zposvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zposvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *af, armpl_int_t ldaf,
                                char *equed, double *s,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *x, armpl_int_t ldx,
                                double *rcond, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2207 LAPACKE_zposvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zposvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            armpl_doublecomplex_t *af, armpl_int_t ldaf,
                            char *equed, double *s, armpl_doublecomplex_t *b,
                            armpl_int_t ldb, armpl_doublecomplex_t *x,
                            armpl_int_t ldx, double *rcond, double *rpvgrw,
                            double *berr, armpl_int_t n_err_bnds,
                            double *err_bnds_norm, double *err_bnds_comp,
                            armpl_int_t nparams, double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2209 LAPACKE_zpotrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpotrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf*, *LAPACKE_dpotrf*, *LAPACKE_spotrf* and *LAPACKE_zpotrf*. It also exists with a native Fortran interface as *zpotrf*.

4.19.2210 LAPACKE_zpotrf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpotrf2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_doublecomplex_t *a,
                            armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf2*, *LAPACKE_dpotrf2*, *LAPACKE_spotrf2* and *LAPACKE_zpotrf2*. It also exists with a native Fortran interface as *zpotrf2*.

4.19.2211 LAPACKE_zpotrf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpotrf2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_doublecomplex_t *a,
                                 armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf2_work*, *LAPACKE_dpotrf2_work*, *LAPACKE_spotrf2_work* and *LAPACKE_zpotrf2_work*.

4.19.2212 LAPACKE_zpotrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpotrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrf_work*, *LAPACKE_dpotrf_work*, *LAPACKE_spotrf_work* and *LAPACKE_zpotrf_work*.

4.19.2213 LAPACKE_zpotri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpotri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotri*, *LAPACKE_dpotri*, *LAPACKE_spotri* and *LAPACKE_zpotri*. It also exists with a native Fortran interface as *zpotri*.

4.19.2214 LAPACKE_zpotri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpotri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotri_work*, *LAPACKE_dpotri_work*, *LAPACKE_spotri_work* and *LAPACKE_zpotri_work*.

4.19.2215 LAPACKE_zpotrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpotrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrs*, *LAPACKE_dpotrs*, *LAPACKE_spotrs* and *LAPACKE_zpotrs*. It also exists with a native Fortran interface as *zpotrs*.

4.19.2216 LAPACKE_zpotrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpotrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpotrs_work*, *LAPACKE_dpotrs_work*, *LAPACKE_spotrs_work* and *LAPACKE_zpotrs_work*.

4.19.2217 LAPACKE_zppcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zppcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *ap,
                           double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppcon*, *LAPACKE_dppcon*, *LAPACKE_sppcon* and *LAPACKE_zppcon*. It also exists with a native Fortran interface as *zppcon*.

4.19.2218 LAPACKE_zppcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zppcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_doublecomplex_t *ap, double anorm,
                                double *rcond, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppcon_work*, *LAPACKE_dppcon_work*, *LAPACKE_sppcon_work* and *LAPACKE_zppcon_work*.

4.19.2219 LAPACKE_zppequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zppequ(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *ap,
                           double *s, double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppequ*, *LAPACKE_dppequ*, *LAPACKE_sppequ* and *LAPACKE_zppequ*. It also exists with a native Fortran interface as *zppequ*.

4.19.2220 LAPACKE_zppequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zppequ_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_doublecomplex_t *ap, double *s,
                                double *scond, double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppequ_work*, *LAPACKE_dppequ_work*, *LAPACKE_sppequ_work* and *LAPACKE_zppequ_work*.

4.19.2221 LAPACKE_zpprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           const armpl_doublecomplex_t *afp,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpprfs*, *LAPACKE_dpprfs*, *LAPACKE_spprfs* and *LAPACKE_zpprfs*. It also exists with a native Fortran interface as *zpprfs*.

4.19.2222 LAPACKE_zpprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                const armpl_doublecomplex_t *afp,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpprfs_work*, *LAPACKE_dpprfs_work*, *LAPACKE_spprfs_work* and *LAPACKE_zpprfs_work*.

4.19.2223 LAPACKE_zppsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zppsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_doublecomplex_t *ap,
                          armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsv*, *LAPACKE_dppsv*, *LAPACKE_sppsv* and *LAPACKE_zppsv*. It also exists with a native Fortran interface as *zppsv*.

4.19.2224 LAPACKE_zppsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zppsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_doublecomplex_t *ap,
                               armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsv_work*, *LAPACKE_dppsv_work*, *LAPACKE_sppsv_work* and *LAPACKE_zppsv_work*.

4.19.2225 LAPACKE_zppsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zppsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_doublecomplex_t *ap,
                           armpl_doublecomplex_t *afp, char *equed, double *s,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *rcond, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsvx*, *LAPACKE_dppsvx*, *LAPACKE_sppsvx* and *LAPACKE_zppsvx*. It also exists with a native Fortran interface as *zppsvx*.

4.19.2226 LAPACKE_zppsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zppsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                armpl_doublecomplex_t *ap,
                                armpl_doublecomplex_t *afp, char *equed,
                                double *s, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cppsvx_work*, *LAPACKE_dppsvx_work*, *LAPACKE_sppsvx_work* and *LAPACKE_zppsvx_work*.

4.19.2227 LAPACKE_zpptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrf*, *LAPACKE_dpptrf*, *LAPACKE_spptrf* and *LAPACKE_zpptrf*. It also exists with a native Fortran interface as *zpptrf*.

4.19.2228 LAPACKE_zpptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrf_work*, *LAPACKE_dpptrf_work*, *LAPACKE_spptrf_work* and *LAPACKE_zpptrf_work*.

4.19.2229 LAPACKE_zpptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptri*, *LAPACKE_dpptri*, *LAPACKE_spptri* and *LAPACKE_zpptri*. It also exists with a native Fortran interface as *zpptri*.

4.19.2230 LAPACKE_zpptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptri_work*, *LAPACKE_dpptri_work*, *LAPACKE_spptri_work* and *LAPACKE_zpptri_work*.

4.19.2231 LAPACKE_zpptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrs*, *LAPACKE_dpptrs*, *LAPACKE_spptrs* and *LAPACKE_zpptrs*. It also exists with a native Fortran interface as *zpptrs*.

4.19.2232 LAPACKE_zpptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpptrs_work*, *LAPACKE_dpptrs_work*, *LAPACKE_spptrs_work* and *LAPACKE_zpptrs_work*.

4.19.2233 LAPACKE_zpstrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpstrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *piv,
                           armpl_int_t *rank, double tol);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpstrf*, *LAPACKE_dpstrf*, *LAPACKE_spstrf* and *LAPACKE_zpstrf*. It also exists with a native Fortran interface as *zpstrf*.

4.19.2234 LAPACKE_zpstrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpstrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *piv,
                                armpl_int_t *rank, double tol, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpstrf_work*, *LAPACKE_dpstrf_work*, *LAPACKE_spstrf_work* and *LAPACKE_zpstrf_work*.

4.19.2235 LAPACKE_zptcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zptcon(armpl_int_t n, const double *d,
                           const armpl_doublecomplex_t *e, double anorm,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptcon*, *LAPACKE_dptcon*, *LAPACKE_sptcon* and *LAPACKE_zptcon*. It also exists with a native Fortran interface as *zptcon*.

4.19.2236 LAPACKE_zptcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zptcon_work(armpl_int_t n, const double *d,
                                const armpl_doublecomplex_t *e, double anorm,
                                double *rcond, double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptcon_work*, *LAPACKE_dptcon_work*, *LAPACKE_sptcon_work* and *LAPACKE_zptcon_work*.

4.19.2237 LAPACKE_zpteqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpteqr(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, double *d, double *e,
                           armpl_doublecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpteqr*, *LAPACKE_dpteqr*, *LAPACKE_spteqr* and *LAPACKE_zpteqr*. It also exists with a native Fortran interface as *zpteqr*.

4.19.2238 LAPACKE_zpteqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpteqr_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, double *d, double *e,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpteqr_work*, *LAPACKE_dpteqr_work*, *LAPACKE_spteqr_work* and *LAPACKE_zpteqr_work*.

4.19.2239 LAPACKE_zptrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zptrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *d,
                           const armpl_doublecomplex_t *e, const double *df,
                           const armpl_doublecomplex_t *ef,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptrfs*, *LAPACKE_dptrfs*, *LAPACKE_sptrfs* and *LAPACKE_zptrfs*. It also exists with a native Fortran interface as *zptrfs*.

4.19.2240 LAPACKE_zptrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zptrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *d,
                                const armpl_doublecomplex_t *e,
                                const double *df,
                                const armpl_doublecomplex_t *ef,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptrfs_work*, *LAPACKE_dptrfs_work*, *LAPACKE_sptrfs_work* and *LAPACKE_zptrfs_work*.

4.19.2241 LAPACKE_zptsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zptsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, double *d,
                          armpl_doublecomplex_t *e, armpl_doublecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsv*, *LAPACKE_dptsv*, *LAPACKE_sptsv* and *LAPACKE_zptsv*. It also exists with a native Fortran interface as *zptsv*.

4.19.2242 LAPACKE_zptsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zptsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, double *d,
                               armpl_doublecomplex_t *e,
                               armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsv_work*, *LAPACKE_dptsv_work*, *LAPACKE_sptsv_work* and *LAPACKE_zptsv_work*.

4.19.2243 LAPACKE_zptsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zptsvx(armpl_int_t matrix_layout, char fact,
                           armpl_int_t n, armpl_int_t nrhs, const double *d,
                           const armpl_doublecomplex_t *e, double *df,
                           armpl_doublecomplex_t *ef,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *rcond, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsvx*, *LAPACKE_dptsvx*, *LAPACKE_sptsvx* and *LAPACKE_zptsvx*. It also exists with a native Fortran interface as *zptsvx*.

4.19.2244 LAPACKE_zptsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zptsvx_work(armpl_int_t matrix_layout, char fact,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *d,
                                const armpl_doublecomplex_t *e, double *df,
                                armpl_doublecomplex_t *ef,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cptsvx_work*, *LAPACKE_dptsvx_work*, *LAPACKE_sptsvx_work* and *LAPACKE_zptsvx_work*.

4.19.2245 LAPACKE_zpttrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpttrf(armpl_int_t n, double *d,
                           armpl_doublecomplex_t *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrf*, *LAPACKE_dpttrf*, *LAPACKE_spttrf* and *LAPACKE_zpttrf*. It also exists with a native Fortran interface as *zpttrf*.

4.19.2246 LAPACKE_zpttrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpttrf_work(armpl_int_t n, double *d,
                                armpl_doublecomplex_t *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrf_work*, *LAPACKE_dpttrf_work*, *LAPACKE_spttrf_work* and *LAPACKE_zpttrf_work*.

4.19.2247 LAPACKE_zpttrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpttrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs, const double *d,
                           const armpl_doublecomplex_t *e,
                           armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrs*, *LAPACKE_dpttrs*, *LAPACKE_spttrs* and *LAPACKE_zpttrs*. It also exists with a native Fortran interface as *zpttrs*.

4.19.2248 LAPACKE_zpttrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zpttrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const double *d,
                                const armpl_doublecomplex_t *e,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cpttrs_work*, *LAPACKE_dpttrs_work*, *LAPACKE_spttrs_work* and *LAPACKE_zpttrs_work*.

4.19.2249 LAPACKE_zspcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zspcon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *ap,
                           const armpl_int_t *ipiv, double anorm,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspcon*, *LAPACKE_dspcon*, *LAPACKE_sspcon* and *LAPACKE_zspcon*. It also exists with a native Fortran interface as *zspcon*.

4.19.2250 LAPACKE_zspcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zspcon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_doublecomplex_t *ap,
                                const armpl_int_t *ipiv, double anorm,
                                double *rcond, armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspcon_work*, *LAPACKE_dspcon_work*, *LAPACKE_sspcon_work* and *LAPACKE_zspcon_work*.

4.19.2251 LAPACKE_zsprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsprfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           const armpl_doublecomplex_t *afp,
                           const armpl_int_t *ipiv,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csprfs*, *LAPACKE_dsprfs*, *LAPACKE_ssprfs* and *LAPACKE_zsprfs*. It also exists with a native Fortran interface as *zsprfs*.

4.19.2252 LAPACKE_zsprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsprfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                const armpl_doublecomplex_t *afp,
                                const armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csprfs_work*, *LAPACKE_dsprfs_work*, *LAPACKE_ssprfs_work* and *LAPACKE_zsprfs_work*.

4.19.2253 LAPACKE_zspsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zspsv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_doublecomplex_t *ap,
                          armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsv*, *LAPACKE_dspsv*, *LAPACKE_sspsv* and *LAPACKE_zspsv*. It also exists with a native Fortran interface as *zspsv*.

4.19.2254 LAPACKE_zspsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zspsv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_doublecomplex_t *ap, armpl_int_t *ipiv,
                               armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsv_work*, *LAPACKE_dspsv_work*, *LAPACKE_sspsv_work* and *LAPACKE_zspsv_work*.

4.19.2255 LAPACKE_zspsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zspsvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           armpl_doublecomplex_t *afp, armpl_int_t *ipiv,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *rcond, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsvx*, *LAPACKE_dspsvx*, *LAPACKE_sspsvx* and *LAPACKE_zspsvx*. It also exists with a native Fortran interface as *zspsvx*.

4.19.2256 LAPACKE_zspsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zspsvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                armpl_doublecomplex_t *afp, armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cspsvx_work*, *LAPACKE_dspsvx_work*, *LAPACKE_sspsvx_work* and *LAPACKE_zspsvx_work*.

4.19.2257 LAPACKE_zsptrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsptrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *ap,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrf*, *LAPACKE_dsptrf*, *LAPACKE_ssptrf* and *LAPACKE_zsptrf*. It also exists with a native Fortran interface as *zsptrf*.

4.19.2258 LAPACKE_zsptrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsptrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *ap,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrf_work*, *LAPACKE_dsptrf_work*, *LAPACKE_ssptrf_work* and *LAPACKE_zsptrf_work*.

4.19.2259 LAPACKE_zsptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsptri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *ap,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptri*, *LAPACKE_dsptri*, *LAPACKE_ssptri* and *LAPACKE_zsptri*. It also exists with a native Fortran interface as *zsptri*.

4.19.2260 LAPACKE_zsptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsptri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *ap,
                                const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptri_work*, *LAPACKE_dsptri_work*, *LAPACKE_ssptri_work* and *LAPACKE_zsptri_work*.

4.19.2261 LAPACKE_zsptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsptrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrs*, *LAPACKE_dsptrs*, *LAPACKE_ssptrs* and *LAPACKE_zsptrs*. It also exists with a native Fortran interface as *zsptrs*.

4.19.2262 LAPACKE_zsptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsptrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csptrs_work*, *LAPACKE_dsptrs_work*, *LAPACKE_ssptrs_work* and *LAPACKE_zsptrs_work*.

4.19.2263 LAPACKE_zstedc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zstedc(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, double *d, double *e,
                           armpl_doublecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstedc*, *LAPACKE_dstedc*, *LAPACKE_sstedc* and *LAPACKE_zstedc*. It also exists with a native Fortran interface as *zstedc*.

4.19.2264 LAPACKE_zstedc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zstedc_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, double *d, double *e,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork,
                                armpl_int_t lrwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstedc_work*, *LAPACKE_dstedc_work*, *LAPACKE_sstedc_work* and *LAPACKE_zstedc_work*.

4.19.2265 LAPACKE_zstegr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zstegr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, double *d, double *e, double vl,
                           double vu, armpl_int_t il, armpl_int_t iu,
                           double abstol, armpl_int_t *m, double *w,
                           armpl_doublecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *isuppz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstegr*, *LAPACKE_dstegr*, *LAPACKE_sstegr* and *LAPACKE_zstegr*. It also exists with a native Fortran interface as *zstegr*.

4.19.2266 LAPACKE_zstegr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zstegr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, double *d,
                                double *e, double vl, double vu,
                                armpl_int_t il, armpl_int_t iu, double abstol,
                                armpl_int_t *m, double *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_int_t *isuppz, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2267 LAPACKE_zstein

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zstein(armpl_int_t matrix_layout, armpl_int_t n,
                           const double *d, const double *e, armpl_int_t m,
                           const double *w, const armpl_int_t *iblock,
                           const armpl_int_t *isplit,
                           armpl_doublecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *ifailv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstein*, *LAPACKE_dstein*, *LAPACKE_sstein* and *LAPACKE_zstein*. It also exists with a native Fortran interface as *zstein*.

4.19.2268 LAPACKE_zstein_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zstein_work(armpl_int_t matrix_layout, armpl_int_t n,
                                const double *d, const double *e,
                                armpl_int_t m, const double *w,
                                const armpl_int_t *iblock,
                                const armpl_int_t *isplit,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                double *work, armpl_int_t *iwork,
                                armpl_int_t *ifailv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstein_work*, *LAPACKE_dstein_work*, *LAPACKE_sstein_work* and *LAPACKE_zstein_work*.

4.19.2269 LAPACKE_zstemr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zstemr(armpl_int_t matrix_layout, char jobz, char range,
                           armpl_int_t n, double *d, double *e, double vl,
                           double vu, armpl_int_t il, armpl_int_t iu,
                           armpl_int_t *m, double *w,
                           armpl_doublecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t nzc, armpl_int_t *isuppz,
                           armpl_int_t *tryrac);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstemr*, *LAPACKE_dstemr*, *LAPACKE_sstemr* and *LAPACKE_zstemr*. It also exists with a native Fortran interface as *zstemr*.

4.19.2270 LAPACKE_zstemr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zstemr_work(armpl_int_t matrix_layout, char jobz,
                                char range, armpl_int_t n, double *d,
                                double *e, double vl, double vu,
                                armpl_int_t il, armpl_int_t iu,
                                armpl_int_t *m, double *w,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_int_t nzc, armpl_int_t *isuppz,
                                armpl_int_t *tryrac, double *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cstemr_work*, *LAPACKE_dstemr_work*, *LAPACKE_sstemr_work* and *LAPACKE_zstemr_work*.

4.19.2271 LAPACKE_zsteqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsteqr(armpl_int_t matrix_layout, char compz,
                           armpl_int_t n, double *d, double *e,
                           armpl_doublecomplex_t *z, armpl_int_t ldz);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csteqr*, *LAPACKE_dsteqr*, *LAPACKE_ssteqr* and *LAPACKE_zsteqr*. It also exists with a native Fortran interface as *zsteqr*.

4.19.2272 LAPACKE_zsteqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsteqr_work(armpl_int_t matrix_layout, char compz,
                                armpl_int_t n, double *d, double *e,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                double *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csteqr_work*, *LAPACKE_dsteqr_work*, *LAPACKE_ssteqr_work* and *LAPACKE_zsteqr_work*.

4.19.2273 LAPACKE_zsycon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsycon(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, const armpl_int_t *ipiv,
                           double anorm, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon*, *LAPACKE_dsycon*, *LAPACKE_ssycon* and *LAPACKE_zsycon*. It also exists with a native Fortran interface as *zsycon*.

4.19.2274 LAPACKE_zsycon_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsycon_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, const armpl_doublecomplex_t *a,
                             armpl_int_t lda, const armpl_doublecomplex_t *e,
                             const armpl_int_t *ipiv, double anorm,
                             double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_3*, *LAPACKE_dsycon_3*, *LAPACKE_ssycon_3* and *LAPACKE_zsycon_3*. It also exists with a native Fortran interface as *zsycon_3*.

4.19.2275 LAPACKE_zsycon_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsycon_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n,
                                  const armpl_doublecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_doublecomplex_t *e,
                                  const armpl_int_t *ipiv, double anorm,
                                  double *rcond,
                                  armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_3_work*, *LAPACKE_dsycon_3_work*, *LAPACKE_ssycon_3_work* and *LAPACKE_zsycon_3_work*.

4.19.2276 LAPACKE_zsycon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsycon_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                double anorm, double *rcond,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csycon_work*, *LAPACKE_dsycon_work*, *LAPACKE_ssycon_work* and *LAPACKE_zsycon_work*.

4.19.2277 LAPACKE_zsyconv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyconv(armpl_int_t matrix_layout, char uplo, char way,
                            armpl_int_t n, armpl_doublecomplex_t *a,
                            armpl_int_t lda, const armpl_int_t *ipiv,
                            armpl_doublecomplex_t *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2278 LAPACKE_zsyconv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyconv_work(armpl_int_t matrix_layout, char uplo,
                                 char way, armpl_int_t n,
                                 armpl_doublecomplex_t *a, armpl_int_t lda,
                                 const armpl_int_t *ipiv,
                                 armpl_doublecomplex_t *e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyconv_work*, *LAPACKE_dsyconv_work*, *LAPACKE_ssyconv_work* and *LAPACKE_zsyconv_work*.

4.19.2279 LAPACKE_zsyequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyequb(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, const armpl_doublecomplex_t *a,
                            armpl_int_t lda, double *s, double *scond,
                            double *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyequb*, *LAPACKE_dsyequb*, *LAPACKE_ssyequb* and *LAPACKE_zsyequb*. It also exists with a native Fortran interface as *zsyequb*.

4.19.2280 LAPACKE_zsyequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyequb_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n,
                                 const armpl_doublecomplex_t *a,
                                 armpl_int_t lda, double *s, double *scond,
                                 double *amax, armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyequb_work*, *LAPACKE_dsyequb_work*, *LAPACKE_ssyequb_work* and *LAPACKE_zsyequb_work*.

4.19.2281 LAPACKE_zsyr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyr(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                         armpl_doublecomplex_t alpha,
                         const armpl_doublecomplex_t *x, armpl_int_t incx,
                         armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyr* and *LAPACKE_zsyr*. It also exists with a native Fortran interface as *zsyr*.

4.19.2282 LAPACKE_zsyr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyr_work(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_doublecomplex_t alpha,
                              const armpl_doublecomplex_t *x,
                              armpl_int_t incx, armpl_doublecomplex_t *a,
                              armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyr_work* and *LAPACKE_zsyr_work*.

4.19.2283 LAPACKE_zsyrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyrfs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *af, armpl_int_t ldaf,
                           const armpl_int_t *ipiv,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2284 LAPACKE_zsyrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyrfs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
```

(continues on next page)

(continued from previous page)

```
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *af,
                                armpl_int_t ldaf, const armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2287 LAPACKE_zsysv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysv(armpl_int_t matrix_layout, char uplo, armpl_int_t n,
                          armpl_int_t nrhs, armpl_doublecomplex_t *a,
                          armpl_int_t lda, armpl_int_t *ipiv,
                          armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv*, *LAPACKE_dsysv*, *LAPACKE_ssysv* and *LAPACKE_zsysv*. It also exists with a native Fortran interface as *zsysv*.

4.19.2288 LAPACKE_zsysv_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysv_aa(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             armpl_doublecomplex_t *a, armpl_int_t lda,
                             armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                             armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_aa*, *LAPACKE_dsysv_aa*, *LAPACKE_ssysv_aa* and *LAPACKE_zsysv_aa*. It also exists with a native Fortran interface as *zsysv_aa*.

4.19.2289 LAPACKE_zsysv_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysv_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs,
                                    armpl_doublecomplex_t *a, armpl_int_t lda,
                                    armpl_doublecomplex_t *tb,
```

(continues on next page)

(continued from previous page)

```
                                    armpl_int_t ltb, armpl_int_t *ipiv,
                                    armpl_int_t *ipiv2,
                                    armpl_doublecomplex_t *b,
                                    armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2290 LAPACKE_zsysv_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysv_aa_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  armpl_doublecomplex_t *a, armpl_int_t lda,
                                  armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                                  armpl_int_t ldb,
                                  armpl_doublecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_aa_work*, *LAPACKE_dsysv_aa_work*, *LAPACKE_ssysv_aa_work* and *LAPACKE_zsysv_aa_work*.

4.19.2291 LAPACKE_zsysv_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysv_rk(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             armpl_doublecomplex_t *a, armpl_int_t lda,
                             armpl_doublecomplex_t *e, armpl_int_t *ipiv,
                             armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rk*, *LAPACKE_dsysv_rk*, *LAPACKE_ssysv_rk* and *LAPACKE_zsysv_rk*. It also exists with a native Fortran interface as *zsysv_rk*.

4.19.2292 LAPACKE_zsysv_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysv_rk_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  armpl_doublecomplex_t *a, armpl_int_t lda,
                                  armpl_doublecomplex_t *e, armpl_int_t *ipiv,
                                  armpl_doublecomplex_t *b, armpl_int_t ldb,
                                  armpl_doublecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rk_work*, *LAPACKE_dsysv_rk_work*, *LAPACKE_ssysv_rk_work* and *LAPACKE_zsysv_rk_work*.

4.19.2293 LAPACKE_zsysv_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysv_rook(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                               armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rook*, *LAPACKE_dsysv_rook*, *LAPACKE_ssysv_rook* and *LAPACKE_zsysv_rook*. It also exists with a native Fortran interface as *zsysv_rook*.

4.19.2294 LAPACKE_zsysv_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysv_rook_work(armpl_int_t matrix_layout, char uplo,
                                    armpl_int_t n, armpl_int_t nrhs,
                                    armpl_doublecomplex_t *a, armpl_int_t lda,
                                    armpl_int_t *ipiv,
                                    armpl_doublecomplex_t *b, armpl_int_t ldb,
                                    armpl_doublecomplex_t *work,
                                    armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_rook_work*, *LAPACKE_dsysv_rook_work*, *LAPACKE_ssysv_rook_work* and *LAPACKE_zsysv_rook_work*.

4.19.2295 LAPACKE_zsysv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysv_work(armpl_int_t matrix_layout, char uplo,
                               armpl_int_t n, armpl_int_t nrhs,
                               armpl_doublecomplex_t *a, armpl_int_t lda,
                               armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                               armpl_int_t ldb, armpl_doublecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysv_work*, *LAPACKE_dsysv_work*, *LAPACKE_ssysv_work* and *LAPACKE_zsysv_work*.

4.19.2296 LAPACKE_zsysvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysvx(armpl_int_t matrix_layout, char fact, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, const armpl_doublecomplex_t *b,
                           armpl_int_t ldb, armpl_doublecomplex_t *x,
                           armpl_int_t ldx, double *rcond, double *ferr,
                           double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvx*, *LAPACKE_dsysvx*, *LAPACKE_ssysvx* and *LAPACKE_zsysvx*. It also exists with a native Fortran interface as *zsysvx*.

4.19.2297 LAPACKE_zsysvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysvx_work(armpl_int_t matrix_layout, char fact,
                                char uplo, armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *af,
                                armpl_int_t ldaf, armpl_int_t *ipiv,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *rcond, double *ferr,
                                double *berr, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2298 LAPACKE_zsysvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysvxx(armpl_int_t matrix_layout, char fact, char uplo,
                            armpl_int_t n, armpl_int_t nrhs,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            armpl_doublecomplex_t *af, armpl_int_t ldaf,
                            armpl_int_t *ipiv, char *equed, double *s,
                            armpl_doublecomplex_t *b, armpl_int_t ldb,
                            armpl_doublecomplex_t *x, armpl_int_t ldx,
                            double *rcond, double *rpvgrw, double *berr,
                            armpl_int_t n_err_bnds, double *err_bnds_norm,
                            double *err_bnds_comp, armpl_int_t nparams,
                            double *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvxx*, *LAPACKE_dsysvxx*, *LAPACKE_ssysvxx* and *LAPACKE_zsysvxx*. It also exists with a native Fortran interface as *zsysvxx*.

4.19.2299 LAPACKE_zsysvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsysvxx_work(armpl_int_t matrix_layout, char fact,
                                 char uplo, armpl_int_t n, armpl_int_t nrhs,
                                 armpl_doublecomplex_t *a, armpl_int_t lda,
                                 armpl_doublecomplex_t *af, armpl_int_t ldaf,
                                 armpl_int_t *ipiv, char *equed, double *s,
                                 armpl_doublecomplex_t *b, armpl_int_t ldb,
                                 armpl_doublecomplex_t *x, armpl_int_t ldx,
                                 double *rcond, double *rpvgrw, double *berr,
                                 armpl_int_t n_err_bnds,
                                 double *err_bnds_norm, double *err_bnds_comp,
                                 armpl_int_t nparams, double *params,
                                 armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csysvxx_work*, *LAPACKE_dsysvxx_work*, *LAPACKE_ssysvxx_work* and *LAPACKE_zsysvxx_work*.

4.19.2300 LAPACKE_zsyswapr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyswapr(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_doublecomplex_t *a,
                             armpl_int_t lda, armpl_int_t i1,
                             armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyswapr*, *LAPACKE_dsyswapr*, *LAPACKE_ssyswapr* and *LAPACKE_zsyswapr*. It also exists with a native Fortran interface as *zsyswapr*.

4.19.2301 LAPACKE_zsyswapr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsyswapr_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_doublecomplex_t *a,
                                  armpl_int_t lda, armpl_int_t i1,
                                  armpl_int_t i2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csyswapr_work*, *LAPACKE_dsyswapr_work*, *LAPACKE_ssyswapr_work* and *LAPACKE_zsyswapr_work*.

4.19.2302 LAPACKE_zsytrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrf(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf*, *LAPACKE_dsytrf*, *LAPACKE_ssytrf* and *LAPACKE_zsytrf*. It also exists with a native Fortran interface as *zsytrf*.

4.19.2303 LAPACKE_zsytrf_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrf_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_doublecomplex_t *a,
                              armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2304 LAPACKE_zsytrf_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrf_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_doublecomplex_t *a,
                                     armpl_int_t lda,
                                     armpl_doublecomplex_t *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa_2stage*, *LAPACKE_dsytrf_aa_2stage*, *LAPACKE_ssytrf_aa_2stage* and *LAPACKE_zsytrf_aa_2stage*. It also exists with a native Fortran interface as *zsytrf_aa_2stage*.

4.19.2305 LAPACKE_zsytrf_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrf_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_doublecomplex_t *a,
                                   armpl_int_t lda, armpl_int_t *ipiv,
                                   armpl_doublecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_aa_work*, *LAPACKE_dsytrf_aa_work*, *LAPACKE_ssytrf_aa_work* and *LAPACKE_zsytrf_aa_work*.

4.19.2306 LAPACKE_zsytrf_rk

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrf_rk(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_doublecomplex_t *a,
                              armpl_int_t lda, armpl_doublecomplex_t *e,
                              armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rk*, *LAPACKE_dsytrf_rk*, *LAPACKE_ssytrf_rk* and *LAPACKE_zsytrf_rk*. It also exists with a native Fortran interface as *zsytrf_rk*.

4.19.2307 LAPACKE_zsytrf_rk_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrf_rk_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_doublecomplex_t *a,
                                   armpl_int_t lda, armpl_doublecomplex_t *e,
                                   armpl_int_t *ipiv,
                                   armpl_doublecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2308 LAPACKE_zsytrf_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrf_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2309 LAPACKE_zsytrf_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrf_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_doublecomplex_t *a,
                                     armpl_int_t lda, armpl_int_t *ipiv,
                                     armpl_doublecomplex_t *work,
                                     armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_rook_work*, *LAPACKE_dsytrf_rook_work*, *LAPACKE_ssytrf_rook_work* and *LAPACKE_zsytrf_rook_work*.

4.19.2310 LAPACKE_zsytrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrf_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrf_work*, *LAPACKE_dsytrf_work*, *LAPACKE_ssytrf_work* and *LAPACKE_zsytrf_work*.

4.19.2311 LAPACKE_zsytri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytri(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri*, *LAPACKE_dsytri*, *LAPACKE_ssytri* and *LAPACKE_zsytri*. It also exists with a native Fortran interface as *zsytri*.

4.19.2312 LAPACKE_zsytri2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytri2(armpl_int_t matrix_layout, char uplo,
                            armpl_int_t n, armpl_doublecomplex_t *a,
                            armpl_int_t lda, const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2*, *LAPACKE_dsytri2*, *LAPACKE_ssytri2* and *LAPACKE_zsytri2*. It also exists with a native Fortran interface as *zsytri2*.

4.19.2313 LAPACKE_zsytri2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytri2_work(armpl_int_t matrix_layout, char uplo,
                                 armpl_int_t n, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, const armpl_int_t *ipiv,
                                 armpl_doublecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2_work*, *LAPACKE_dsytri2_work*, *LAPACKE_ssytri2_work* and *LAPACKE_zsytri2_work*.

4.19.2314 LAPACKE_zsytri2x

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytri2x(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_doublecomplex_t *a,
                             armpl_int_t lda, const armpl_int_t *ipiv,
                             armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri2x*, *LAPACKE_dsytri2x*, *LAPACKE_ssytri2x* and *LAPACKE_zsytri2x*. It also exists with a native Fortran interface as *zsytri2x*.

4.19.2315 LAPACKE_zsytri2x_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytri2x_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_doublecomplex_t *a,
                                  armpl_int_t lda, const armpl_int_t *ipiv,
                                  armpl_doublecomplex_t *work,
                                  armpl_int_t nb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2316 LAPACKE_zsytri_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytri_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_doublecomplex_t *a,
                             armpl_int_t lda, const armpl_doublecomplex_t *e,
                             const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytri_3*, *LAPACKE_dsytri_3*, *LAPACKE_ssytri_3* and *LAPACKE_zsytri_3*. It also exists with a native Fortran interface as *zsytri_3*.

4.19.2317 LAPACKE_zsytri_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytri_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_doublecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_doublecomplex_t *e,
                                  const armpl_int_t *ipiv,
                                  armpl_doublecomplex_t *work,
                                  armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2318 LAPACKE_zsytri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytri_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2319 LAPACKE_zsytrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrs(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_int_t *ipiv, armpl_doublecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2322 LAPACKE_zsytrs_3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrs_3(armpl_int_t matrix_layout, char uplo,
                             armpl_int_t n, armpl_int_t nrhs,
                             const armpl_doublecomplex_t *a, armpl_int_t lda,
                             const armpl_doublecomplex_t *e,
                             const armpl_int_t *ipiv,
                             armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2323 LAPACKE_zsytrs_3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrs_3_work(armpl_int_t matrix_layout, char uplo,
                                  armpl_int_t n, armpl_int_t nrhs,
                                  const armpl_doublecomplex_t *a,
                                  armpl_int_t lda,
                                  const armpl_doublecomplex_t *e,
                                  const armpl_int_t *ipiv,
                                  armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_3_work*, *LAPACKE_dsytrs_3_work*, *LAPACKE_ssytrs_3_work* and *LAPACKE_zsytrs_3_work*.

4.19.2324 LAPACKE_zsytrs_aa

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrs_aa(armpl_int_t matrix_layout, char uplo,
                              armpl_int_t n, armpl_int_t nrhs,
                              const armpl_doublecomplex_t *a, armpl_int_t lda,
                              const armpl_int_t *ipiv,
                              armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa*, *LAPACKE_dsytrs_aa*, *LAPACKE_ssytrs_aa* and *LAPACKE_zsytrs_aa*. It also exists with a native Fortran interface as *zsytrs_aa*.

4.19.2325 LAPACKE_zsytrs_aa_2stage

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrs_aa_2stage(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     armpl_doublecomplex_t *a,
                                     armpl_int_t lda,
                                     armpl_doublecomplex_t *tb,
                                     armpl_int_t ltb, armpl_int_t *ipiv,
                                     armpl_int_t *ipiv2,
                                     armpl_doublecomplex_t *b,
                                     armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa_2stage*, *LAPACKE_dsytrs_aa_2stage*, *LAPACKE_ssytrs_aa_2stage* and *LAPACKE_zsytrs_aa_2stage*. It also exists with a native Fortran interface as *zsytrs_aa_2stage*.

4.19.2326 LAPACKE_zsytrs_aa_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrs_aa_work(armpl_int_t matrix_layout, char uplo,
                                   armpl_int_t n, armpl_int_t nrhs,
                                   const armpl_doublecomplex_t *a,
                                   armpl_int_t lda, const armpl_int_t *ipiv,
                                   armpl_doublecomplex_t *b, armpl_int_t ldb,
                                   armpl_doublecomplex_t *work,
                                   armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_aa_work*, *LAPACKE_dsytrs_aa_work*, *LAPACKE_ssytrs_aa_work* and *LAPACKE_zsytrs_aa_work*.

4.19.2327 LAPACKE_zsytrs_rook

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrs_rook(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_csytrs_rook*, *LAPACKE_dsytrs_rook*, *LAPACKE_ssytrs_rook* and *LAPACKE_zsytrs_rook*. It also exists with a native Fortran interface as *zsytrs_rook*.

4.19.2328 LAPACKE_zsytrs_rook_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrs_rook_work(armpl_int_t matrix_layout, char uplo,
                                     armpl_int_t n, armpl_int_t nrhs,
                                     const armpl_doublecomplex_t *a,
                                     armpl_int_t lda, const armpl_int_t *ipiv,
```

(continues on next page)

(continued from previous page)

```
                                    armpl_doublecomplex_t *b,
                                    armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2329 LAPACKE_zsytrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zsytrs_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2330 LAPACKE_ztbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztbcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           const armpl_doublecomplex_t *ab, armpl_int_t ldab,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbcon*, *LAPACKE_dtbcon*, *LAPACKE_stbcon* and *LAPACKE_ztbcon*. It also exists with a native Fortran interface as *ztbcon*.

4.19.2331 LAPACKE_ztbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztbcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                armpl_int_t kd,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, double *rcond,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbcon_work*, *LAPACKE_dtbcon_work*, *LAPACKE_stbcon_work* and *LAPACKE_ztbcon_work*.

4.19.2332 LAPACKE_ztbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztbrfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           armpl_int_t nrhs, const armpl_doublecomplex_t *ab,
                           armpl_int_t ldab, const armpl_doublecomplex_t *b,
                           armpl_int_t ldb, const armpl_doublecomplex_t *x,
                           armpl_int_t ldx, double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbrfs*, *LAPACKE_dtbrfs*, *LAPACKE_stbrfs* and *LAPACKE_ztbrfs*. It also exists with a native Fortran interface as *ztbrfs*.

4.19.2333 LAPACKE_ztbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztbrfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t kd, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb,
                                const armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2334 LAPACKE_ztbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztbtrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t kd,
                           armpl_int_t nrhs, const armpl_doublecomplex_t *ab,
                           armpl_int_t ldab, armpl_doublecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbtrs*, *LAPACKE_dtbtrs*, *LAPACKE_stbtrs* and *LAPACKE_ztbtrs*. It also exists with a native Fortran interface as *ztbtrs*.

4.19.2335 LAPACKE_ztbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztbtrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t kd, armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ab,
                                armpl_int_t ldab, armpl_doublecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctbtrs_work*, *LAPACKE_dtbtrs_work*, *LAPACKE_stbtrs_work* and *LAPACKE_ztbtrs_work*.

4.19.2336 LAPACKE_ztfsm

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztfsm(armpl_int_t matrix_layout, char transr, char side,
                          char uplo, char trans, char diag, armpl_int_t m,
                          armpl_int_t n, armpl_doublecomplex_t alpha,
                          const armpl_doublecomplex_t *a,
                          armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfsm*, *LAPACKE_dtfsm*, *LAPACKE_stfsm* and *LAPACKE_ztfsm*. It also exists with a native Fortran interface as *ztfsm*.

4.19.2337 LAPACKE_ztfsm_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztfsm_work(armpl_int_t matrix_layout, char transr,
                               char side, char uplo, char trans, char diag,
                               armpl_int_t m, armpl_int_t n,
                               armpl_doublecomplex_t alpha,
                               const armpl_doublecomplex_t *a,
                               armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfsm_work*, *LAPACKE_dtfsm_work*, *LAPACKE_stfsm_work* and *LAPACKE_ztfsm_work*.

4.19.2338 LAPACKE_ztftri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztftri(armpl_int_t matrix_layout, char transr, char uplo,
                           char diag, armpl_int_t n,
                           armpl_doublecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctftri*, *LAPACKE_dtftri*, *LAPACKE_stftri* and *LAPACKE_ztftri*. It also exists with a native Fortran interface as *ztftri*.

4.19.2339 LAPACKE_ztftri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztftri_work(armpl_int_t matrix_layout, char transr,
                                char uplo, char diag, armpl_int_t n,
                                armpl_doublecomplex_t *a);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctftri_work*, *LAPACKE_dtftri_work*, *LAPACKE_stftri_work* and *LAPACKE_ztftri_work*.

4.19.2340 LAPACKE_ztfttp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztfttp(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *arf,
                           armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttp*, *LAPACKE_dtfttp*, *LAPACKE_stfttp* and *LAPACKE_ztfttp*. It also exists with a native Fortran interface as *ztfttp*.

4.19.2341 LAPACKE_ztfttp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztfttp_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                const armpl_doublecomplex_t *arf,
                                armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttp_work*, *LAPACKE_dtfttp_work*, *LAPACKE_stfttp_work* and *LAPACKE_ztfttp_work*.

4.19.2342 LAPACKE_ztfttr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztfttr(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *arf,
                           armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttr*, *LAPACKE_dtfttr*, *LAPACKE_stfttr* and *LAPACKE_ztfttr*. It also exists with a native Fortran interface as *ztfttr*.

4.19.2343 LAPACKE_ztfttr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztfttr_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                const armpl_doublecomplex_t *arf,
                                armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctfttr_work*, *LAPACKE_dtfttr_work*, *LAPACKE_stfttr_work* and *LAPACKE_ztfttr_work*.

4.19.2344 LAPACKE_ztgevc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgevc(armpl_int_t matrix_layout, char side, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const armpl_doublecomplex_t *s, armpl_int_t lds,
                           const armpl_doublecomplex_t *p, armpl_int_t ldp,
                           armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                           armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t mm, armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgevc*, *LAPACKE_dtgevc*, *LAPACKE_stgevc* and *LAPACKE_ztgevc*. It also exists with a native Fortran interface as *ztgevc*.

4.19.2345 LAPACKE_ztgevc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgevc_work(armpl_int_t matrix_layout, char side,
                                char howmny, const armpl_int_t *select,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t n, const armpl_doublecomplex_t *s,
                                armpl_int_t lds,
                                const armpl_doublecomplex_t *p,
                                armpl_int_t ldp, armpl_doublecomplex_t *vl,
                                armpl_int_t ldvl, armpl_doublecomplex_t *vr,
                                armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgevc_work*, *LAPACKE_dtgevc_work*, *LAPACKE_stgevc_work* and *LAPACKE_ztgevc_work*.

4.19.2346 LAPACKE_ztgexc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgexc(armpl_int_t matrix_layout, armpl_int_t wantq,
                           armpl_int_t wantz, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *q, armpl_int_t ldq,
                           armpl_doublecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t ifst, armpl_int_t ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgexc*, *LAPACKE_dtgexc*, *LAPACKE_stgexc* and *LAPACKE_ztgexc*. It also exists with a native Fortran interface as *ztgexc*.

4.19.2347 LAPACKE_ztgexc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgexc_work(armpl_int_t matrix_layout, armpl_int_t wantq,
                                armpl_int_t wantz, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *q, armpl_int_t ldq,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_int_t ifst, armpl_int_t ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgexc_work*, *LAPACKE_dtgexc_work*, *LAPACKE_stgexc_work* and *LAPACKE_ztgexc_work*.

4.19.2348 LAPACKE_ztgsen

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgsen(armpl_int_t matrix_layout, armpl_int_t ijob,
                           armpl_int_t wantq, armpl_int_t wantz,
                           const armpl_int_t *select, armpl_int_t n,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *alpha,
                           armpl_doublecomplex_t *beta,
                           armpl_doublecomplex_t *q, armpl_int_t ldq,
                           armpl_doublecomplex_t *z, armpl_int_t ldz,
                           armpl_int_t *m, double *pl, double *pr,
                           double *dif);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsen*, *LAPACKE_dtgsen*, *LAPACKE_stgsen* and *LAPACKE_ztgsen*. It also exists with a native Fortran interface as *ztgsen*.

4.19.2349 LAPACKE_ztgsen_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgsen_work(armpl_int_t matrix_layout, armpl_int_t ijob,
                                armpl_int_t wantq, armpl_int_t wantz,
                                const armpl_int_t *select, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *alpha,
                                armpl_doublecomplex_t *beta,
                                armpl_doublecomplex_t *q, armpl_int_t ldq,
                                armpl_doublecomplex_t *z, armpl_int_t ldz,
                                armpl_int_t *m, double *pl, double *pr,
                                double *dif, armpl_doublecomplex_t *work,
                                armpl_int_t lwork, armpl_int_t *iwork,
                                armpl_int_t liwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

                                armpl_int_t ldu, armpl_doublecomplex_t *v,
                                armpl_int_t ldv, armpl_doublecomplex_t *q,
                                armpl_int_t ldq, armpl_int_t *ncycle);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsja*, *LAPACKE_dtgsja*, *LAPACKE_stgsja* and *LAPACKE_ztgsja*. It also exists with a native Fortran interface as *ztgsja*.

4.19.2351 LAPACKE_ztgsja_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgsja_work(armpl_int_t matrix_layout, char jobu,
                                char jobv, char jobq, armpl_int_t m,
                                armpl_int_t p, armpl_int_t n, armpl_int_t k,
                                armpl_int_t l, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, double tola, double tolb,
                                double *alpha, double *beta,
                                armpl_doublecomplex_t *u, armpl_int_t ldu,
                                armpl_doublecomplex_t *v, armpl_int_t ldv,
                                armpl_doublecomplex_t *q, armpl_int_t ldq,
                                armpl_doublecomplex_t *work,
                                armpl_int_t *ncycle);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2352 LAPACKE_ztgsna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgsna(armpl_int_t matrix_layout, char job, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           const armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                           const armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                           double *s, double *dif, armpl_int_t mm,
                           armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsna*, *LAPACKE_dtgsna*, *LAPACKE_stgsna* and *LAPACKE_ztgsna*. It also exists with a native Fortran interface as *ztgsna*.

4.19.2353 LAPACKE_ztgsna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgsna_work(armpl_int_t matrix_layout, char job,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb,
                                const armpl_doublecomplex_t *vl,
                                armpl_int_t ldvl,
                                const armpl_doublecomplex_t *vr,
                                armpl_int_t ldvr, double *s, double *dif,
                                armpl_int_t mm, armpl_int_t *m,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2354 LAPACKE_ztgsyl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgsyl(armpl_int_t matrix_layout, char trans,
                           armpl_int_t ijob, armpl_int_t m, armpl_int_t n,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *c, armpl_int_t ldc,
                           const armpl_doublecomplex_t *d, armpl_int_t ldd,
                           const armpl_doublecomplex_t *e, armpl_int_t lde,
                           armpl_doublecomplex_t *f, armpl_int_t ldf,
                           double *scale, double *dif);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsyl*, *LAPACKE_dtgsyl*, *LAPACKE_stgsyl* and *LAPACKE_ztgsyl*. It also exists with a native Fortran interface as *ztgsyl*.

4.19.2355 LAPACKE_ztgsyl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztgsyl_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t ijob, armpl_int_t m,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *c,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldc,
                                const armpl_doublecomplex_t *d,
                                armpl_int_t ldd,
                                const armpl_doublecomplex_t *e,
                                armpl_int_t lde, armpl_doublecomplex_t *f,
                                armpl_int_t ldf, double *scale, double *dif,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctgsyl_work*, *LAPACKE_dtgsyl_work*, *LAPACKE_stgsyl_work* and *LAPACKE_ztgsyl_work*.

4.19.2356 LAPACKE_ztpcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n,
                           const armpl_doublecomplex_t *ap, double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpcon*, *LAPACKE_dtpcon*, *LAPACKE_stpcon* and *LAPACKE_ztpcon*. It also exists with a native Fortran interface as *ztpcon*.

4.19.2357 LAPACKE_ztpcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                const armpl_doublecomplex_t *ap,
                                double *rcond, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpcon_work*, *LAPACKE_dtpcon_work*, *LAPACKE_stpcon_work* and *LAPACKE_ztpcon_work*.

4.19.2358 LAPACKE_ztpmqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpmqrt(armpl_int_t matrix_layout, char side, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t k,
                            armpl_int_t l, armpl_int_t nb,
                            const armpl_doublecomplex_t *v, armpl_int_t ldv,
                            const armpl_doublecomplex_t *t, armpl_int_t ldt,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpmqrt*, *LAPACKE_dtpmqrt*, *LAPACKE_stpmqrt* and *LAPACKE_ztpmqrt*. It also exists with a native Fortran interface as *ztpmqrt*.

4.19.2359 LAPACKE_ztpmqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpmqrt_work(armpl_int_t matrix_layout, char side,
                                 char trans, armpl_int_t m, armpl_int_t n,
                                 armpl_int_t k, armpl_int_t l, armpl_int_t nb,
                                 const armpl_doublecomplex_t *v,
                                 armpl_int_t ldv,
                                 const armpl_doublecomplex_t *t,
                                 armpl_int_t ldt, armpl_doublecomplex_t *a,
                                 armpl_int_t lda, armpl_doublecomplex_t *b,
                                 armpl_int_t ldb,
                                 armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpmqrt_work*, *LAPACKE_dtpmqrt_work*, *LAPACKE_stpmqrt_work* and *LAPACKE_ztpmqrt_work*.

4.19.2360 LAPACKE_ztpqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpqrt(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t l, armpl_int_t nb,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt*, *LAPACKE_dtpqrt*, *LAPACKE_stpqrt* and *LAPACKE_ztpqrt*. It also exists with a native Fortran interface as *ztpqrt*.

4.19.2361 LAPACKE_ztpqrt2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpqrt2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_int_t l,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            armpl_doublecomplex_t *b, armpl_int_t ldb,
                            armpl_doublecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt2*, *LAPACKE_dtpqrt2*, *LAPACKE_stpqrt2* and *LAPACKE_ztpqrt2*. It also exists with a native Fortran interface as *ztpqrt2*.

4.19.2362 LAPACKE_ztpqrt2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpqrt2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t l,
                                 armpl_doublecomplex_t *a, armpl_int_t lda,
                                 armpl_doublecomplex_t *b, armpl_int_t ldb,
                                 armpl_doublecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt2_work*, *LAPACKE_dtpqrt2_work*, *LAPACKE_stpqrt2_work* and *LAPACKE_ztpqrt2_work*.

4.19.2363 LAPACKE_ztpqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpqrt_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t l, armpl_int_t nb,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                armpl_doublecomplex_t *b, armpl_int_t ldb,
                                armpl_doublecomplex_t *t, armpl_int_t ldt,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpqrt_work*, *LAPACKE_dtpqrt_work*, *LAPACKE_stpqrt_work* and *LAPACKE_ztpqrt_work*.

4.19.2364 LAPACKE_ztprfb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztprfb(armpl_int_t matrix_layout, char side, char trans,
                           char direct, char storev, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k, armpl_int_t l,
```

(continues on next page)

(continued from previous page)

```
                            const armpl_doublecomplex_t *v, armpl_int_t ldv,
                            const armpl_doublecomplex_t *t, armpl_int_t ldt,
                            armpl_doublecomplex_t *a, armpl_int_t lda,
                            armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfb*, *LAPACKE_dtprfb*, *LAPACKE_stprfb* and *LAPACKE_ztprfb*. It also exists with a native Fortran interface as *ztprfb*.

4.19.2365 LAPACKE_ztprfb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztprfb_work(armpl_int_t matrix_layout, char side,
                                char trans, char direct, char storev,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                armpl_int_t l, const armpl_doublecomplex_t *v,
                                armpl_int_t ldv,
                                const armpl_doublecomplex_t *t,
                                armpl_int_t ldt, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *work,
                                armpl_int_t ldwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctprfb_work*, *LAPACKE_dtprfb_work*, *LAPACKE_stprfb_work* and *LAPACKE_ztprfb_work*.

4.19.2366 LAPACKE_ztprfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztprfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           const armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2367 LAPACKE_ztprfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztprfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb,
                                const armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2368 LAPACKE_ztptri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztptri(armpl_int_t matrix_layout, char uplo, char diag,
                           armpl_int_t n, armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptri*, *LAPACKE_dtptri*, *LAPACKE_stptri* and *LAPACKE_ztptri*. It also exists with a native Fortran interface as *ztptri*.

4.19.2369 LAPACKE_ztptri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztptri_work(armpl_int_t matrix_layout, char uplo,
                                char diag, armpl_int_t n,
                                armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2370 LAPACKE_ztptrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztptrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *ap,
                           armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptrs*, *LAPACKE_dtptrs*, *LAPACKE_stptrs* and *LAPACKE_ztptrs*. It also exists with a native Fortran interface as *ztptrs*.

4.19.2371 LAPACKE_ztptrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztptrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs,
                                const armpl_doublecomplex_t *ap,
                                armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctptrs_work*, *LAPACKE_dtptrs_work*, *LAPACKE_stptrs_work* and *LAPACKE_ztptrs_work*.

4.19.2372 LAPACKE_ztpttf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpttf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *ap,
                           armpl_doublecomplex_t *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttf*, *LAPACKE_dtpttf*, *LAPACKE_stpttf* and *LAPACKE_ztpttf*. It also exists with a native Fortran interface as *ztpttf*.

4.19.2373 LAPACKE_ztpttf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpttf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                const armpl_doublecomplex_t *ap,
                                armpl_doublecomplex_t *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttf_work*, *LAPACKE_dtpttf_work*, *LAPACKE_stpttf_work* and *LAPACKE_ztpttf_work*.

4.19.2374 LAPACKE_ztpttr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpttr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *ap,
                           armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttr*, *LAPACKE_dtpttr*, *LAPACKE_stpttr* and *LAPACKE_ztpttr*. It also exists with a native Fortran interface as *ztpttr*.

4.19.2375 LAPACKE_ztpttr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztpttr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_doublecomplex_t *ap,
                                armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctpttr_work*, *LAPACKE_dtpttr_work*, *LAPACKE_stpttr_work* and *LAPACKE_ztpttr_work*.

4.19.2376 LAPACKE_ztrcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrcon(armpl_int_t matrix_layout, char norm, char uplo,
                           char diag, armpl_int_t n,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           double *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrcon*, *LAPACKE_dtrcon*, *LAPACKE_strcon* and *LAPACKE_ztrcon*. It also exists with a native Fortran interface as *ztrcon*.

4.19.2377 LAPACKE_ztrcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrcon_work(armpl_int_t matrix_layout, char norm,
                                char uplo, char diag, armpl_int_t n,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, double *rcond,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrcon_work*, *LAPACKE_dtrcon_work*, *LAPACKE_strcon_work* and *LAPACKE_ztrcon_work*.

4.19.2378 LAPACKE_ztrevc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrevc(armpl_int_t matrix_layout, char side, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           armpl_doublecomplex_t *t, armpl_int_t ldt,
                           armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                           armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t mm, armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrevc*, *LAPACKE_dtrevc*, *LAPACKE_strevc* and *LAPACKE_ztrevc*. It also exists with a native Fortran interface as *ztrevc*.

4.19.2379 LAPACKE_ztrevc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrevc_work(armpl_int_t matrix_layout, char side,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, armpl_doublecomplex_t *t,
                                armpl_int_t ldt, armpl_doublecomplex_t *vl,
                                armpl_int_t ldvl, armpl_doublecomplex_t *vr,
                                armpl_int_t ldvr, armpl_int_t mm,
                                armpl_int_t *m, armpl_doublecomplex_t *work,
                                double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrevc_work*, *LAPACKE_dtrevc_work*, *LAPACKE_strevc_work* and *LAPACKE_ztrevc_work*.

4.19.2380 LAPACKE_ztrexc

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrexc(armpl_int_t matrix_layout, char compq,
                           armpl_int_t n, armpl_doublecomplex_t *t,
                           armpl_int_t ldt, armpl_doublecomplex_t *q,
                           armpl_int_t ldq, armpl_int_t ifst,
                           armpl_int_t ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrexc*, *LAPACKE_dtrexc*, *LAPACKE_strexc* and *LAPACKE_ztrexc*. It also exists with a native Fortran interface as *ztrexc*.

4.19.2381 LAPACKE_ztrexc_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrexc_work(armpl_int_t matrix_layout, char compq,
                                armpl_int_t n, armpl_doublecomplex_t *t,
                                armpl_int_t ldt, armpl_doublecomplex_t *q,
                                armpl_int_t ldq, armpl_int_t ifst,
                                armpl_int_t ilst);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrexc_work*, *LAPACKE_dtrexc_work*, *LAPACKE_strexc_work* and *LAPACKE_ztrexc_work*.

4.19.2382 LAPACKE_ztrrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrrfs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           const armpl_doublecomplex_t *x, armpl_int_t ldx,
                           double *ferr, double *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrrfs*, *LAPACKE_dtrrfs*, *LAPACKE_strrfs* and *LAPACKE_ztrrfs*. It also exists with a native Fortran interface as *ztrrfs*.

4.19.2383 LAPACKE_ztrrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrrfs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs,
```

(continues on next page)

(continued from previous page)

```
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb,
                                const armpl_doublecomplex_t *x,
                                armpl_int_t ldx, double *ferr, double *berr,
                                armpl_doublecomplex_t *work, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2384 LAPACKE_ztrsen

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrsen(armpl_int_t matrix_layout, char job, char compq,
                           const armpl_int_t *select, armpl_int_t n,
                           armpl_doublecomplex_t *t, armpl_int_t ldt,
                           armpl_doublecomplex_t *q, armpl_int_t ldq,
                           armpl_doublecomplex_t *w, armpl_int_t *m,
                           double *s, double *sep);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsen*, *LAPACKE_dtrsen*, *LAPACKE_strsen* and *LAPACKE_ztrsen*. It also exists with a native Fortran interface as *ztrsen*.

4.19.2385 LAPACKE_ztrsen_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrsen_work(armpl_int_t matrix_layout, char job,
                                char compq, const armpl_int_t *select,
                                armpl_int_t n, armpl_doublecomplex_t *t,
                                armpl_int_t ldt, armpl_doublecomplex_t *q,
                                armpl_int_t ldq, armpl_doublecomplex_t *w,
                                armpl_int_t *m, double *s, double *sep,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2386 LAPACKE_ztrsna

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrsna(armpl_int_t matrix_layout, char job, char howmny,
                           const armpl_int_t *select, armpl_int_t n,
                           const armpl_doublecomplex_t *t, armpl_int_t ldt,
                           const armpl_doublecomplex_t *vl, armpl_int_t ldvl,
                           const armpl_doublecomplex_t *vr, armpl_int_t ldvr,
                           double *s, double *sep, armpl_int_t mm,
                           armpl_int_t *m);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsna*, *LAPACKE_dtrsna*, *LAPACKE_strsna* and *LAPACKE_ztrsna*. It also exists with a native Fortran interface as *ztrsna*.

4.19.2387 LAPACKE_ztrsna_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrsna_work(armpl_int_t matrix_layout, char job,
                                char howmny, const armpl_int_t *select,
                                armpl_int_t n, const armpl_doublecomplex_t *t,
                                armpl_int_t ldt,
                                const armpl_doublecomplex_t *vl,
                                armpl_int_t ldvl,
                                const armpl_doublecomplex_t *vr,
                                armpl_int_t ldvr, double *s, double *sep,
                                armpl_int_t mm, armpl_int_t *m,
                                armpl_doublecomplex_t *work,
                                armpl_int_t ldwork, double *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsna_work*, *LAPACKE_dtrsna_work*, *LAPACKE_strsna_work* and *LAPACKE_ztrsna_work*.

4.19.2388 LAPACKE_ztrsyl

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrsyl(armpl_int_t matrix_layout, char trana, char tranb,
                           armpl_int_t isgn, armpl_int_t m, armpl_int_t n,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *b, armpl_int_t ldb,
                           armpl_doublecomplex_t *c, armpl_int_t ldc,
                           double *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsyl*, *LAPACKE_dtrsyl*, *LAPACKE_strsyl* and *LAPACKE_ztrsyl*. It also exists with a native Fortran interface as *ztrsyl*.

4.19.2389 LAPACKE_ztrsyl_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrsyl_work(armpl_int_t matrix_layout, char trana,
                                char tranb, armpl_int_t isgn, armpl_int_t m,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *b,
                                armpl_int_t ldb, armpl_doublecomplex_t *c,
                                armpl_int_t ldc, double *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrsyl_work*, *LAPACKE_dtrsyl_work*, *LAPACKE_strsyl_work* and *LAPACKE_ztrsyl_work*.

4.19.2390 LAPACKE_ztrtri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrtri(armpl_int_t matrix_layout, char uplo, char diag,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtri*, *LAPACKE_dtrtri*, *LAPACKE_strtri* and *LAPACKE_ztrtri*. It also exists with a native Fortran interface as *ztrtri*.

4.19.2391 LAPACKE_ztrtri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrtri_work(armpl_int_t matrix_layout, char uplo,
                                char diag, armpl_int_t n,
                                armpl_doublecomplex_t *a, armpl_int_t lda);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtri_work*, *LAPACKE_dtrtri_work*, *LAPACKE_strtri_work* and *LAPACKE_ztrtri_work*.

4.19.2392 LAPACKE_ztrtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrtrs(armpl_int_t matrix_layout, char uplo, char trans,
                           char diag, armpl_int_t n, armpl_int_t nrhs,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           armpl_doublecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtrs*, *LAPACKE_dtrtrs*, *LAPACKE_strtrs* and *LAPACKE_ztrtrs*. It also exists with a native Fortran interface as *ztrtrs*.

4.19.2393 LAPACKE_ztrtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrtrs_work(armpl_int_t matrix_layout, char uplo,
                                char trans, char diag, armpl_int_t n,
                                armpl_int_t nrhs,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *b,
                                armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrtrs_work*, *LAPACKE_dtrtrs_work*, *LAPACKE_strtrs_work* and *LAPACKE_ztrtrs_work*.

4.19.2394 LAPACKE_ztrttf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrttf(armpl_int_t matrix_layout, char transr, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttf*, *LAPACKE_dtrttf*, *LAPACKE_strttf* and *LAPACKE_ztrttf*. It also exists with a native Fortran interface as *ztrttf*.

4.19.2395 LAPACKE_ztrttf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrttf_work(armpl_int_t matrix_layout, char transr,
                                char uplo, armpl_int_t n,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *arf);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttf_work*, *LAPACKE_dtrttf_work*, *LAPACKE_strttf_work* and *LAPACKE_ztrttf_work*.

4.19.2396 LAPACKE_ztrttp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrttp(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttp*, *LAPACKE_dtrttp*, *LAPACKE_strttp* and *LAPACKE_ztrttp*. It also exists with a native Fortran interface as *ztrttp*.

4.19.2397 LAPACKE_ztrttp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztrttp_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *ap);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctrttp_work*, *LAPACKE_dtrttp_work*, *LAPACKE_strttp_work* and *LAPACKE_ztrttp_work*.

4.19.2398 LAPACKE_ztzrzf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztzrzf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda, armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctzrzf*, *LAPACKE_dtzrzf*, *LAPACKE_stzrzf* and *LAPACKE_ztzrzf*. It also exists with a native Fortran interface as *ztzrzf*.

4.19.2399 LAPACKE_ztzrzf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_ztzrzf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda, armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_ctzrzf_work*, *LAPACKE_dtzrzf_work*, *LAPACKE_stzrzf_work* and *LAPACKE_ztzrzf_work*.

4.19.2400 LAPACKE_zunbdb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunbdb(armpl_int_t matrix_layout, char trans, char signs,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           armpl_doublecomplex_t *x11, armpl_int_t ldx11,
                           armpl_doublecomplex_t *x12, armpl_int_t ldx12,
```

(continues on next page)

(continued from previous page)

```
                                armpl_doublecomplex_t *x21, armpl_int_t ldx21,
                                armpl_doublecomplex_t *x22, armpl_int_t ldx22,
                                double *theta, double *phi,
                                armpl_doublecomplex_t *taup1,
                                armpl_doublecomplex_t *taup2,
                                armpl_doublecomplex_t *tauq1,
                                armpl_doublecomplex_t *tauq2);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunbdb* and *LAPACKE_zunbdb*. It also exists with a native Fortran interface as *zunbdb*.

4.19.2401 LAPACKE_zunbdb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunbdb_work(armpl_int_t matrix_layout, char trans,
                                char signs, armpl_int_t m, armpl_int_t p,
                                armpl_int_t q, armpl_doublecomplex_t *x11,
                                armpl_int_t ldx11, armpl_doublecomplex_t *x12,
                                armpl_int_t ldx12, armpl_doublecomplex_t *x21,
                                armpl_int_t ldx21, armpl_doublecomplex_t *x22,
                                armpl_int_t ldx22, double *theta, double *phi,
                                armpl_doublecomplex_t *taup1,
                                armpl_doublecomplex_t *taup2,
                                armpl_doublecomplex_t *tauq1,
                                armpl_doublecomplex_t *tauq2,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.2406 LAPACKE_zungbr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungbr(armpl_int_t matrix_layout, char vect,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungbr* and *LAPACKE_zungbr*. It also exists with a native Fortran interface as *zungbr*.

4.19.2407 LAPACKE_zungbr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungbr_work(armpl_int_t matrix_layout, char vect,
                                armpl_int_t m, armpl_int_t n, armpl_int_t k,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungbr_work* and *LAPACKE_zungbr_work*.

4.19.2408 LAPACKE_zunghr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunghr(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t ilo, armpl_int_t ihi,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunghr* and *LAPACKE_zunghr*. It also exists with a native Fortran interface as *zunghr*.

4.19.2409 LAPACKE_zunghr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunghr_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunghr_work* and *LAPACKE_zunghr_work*.

4.19.2410 LAPACKE_zunglq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunglq(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunglq* and *LAPACKE_zunglq*. It also exists with a native Fortran interface as *zunglq*.

4.19.2411 LAPACKE_zunglq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunglq_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunglq_work* and *LAPACKE_zunglq_work*.

4.19.2412 LAPACKE_zungql

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungql(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungql* and *LAPACKE_zungql*. It also exists with a native Fortran interface as *zungql*.

4.19.2413 LAPACKE_zungql_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungql_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungql_work* and *LAPACKE_zungql_work*.

4.19.2414 LAPACKE_zungqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungqr(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungqr* and *LAPACKE_zungqr*. It also exists with a native Fortran interface as *zungqr*.

4.19.2415 LAPACKE_zungqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungqr_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungqr_work* and *LAPACKE_zungqr_work*.

4.19.2416 LAPACKE_zungrq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungrq(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t k,
                           armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.2417 LAPACKE_zungrq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungrq_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                armpl_doublecomplex_t *a, armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungrq_work* and *LAPACKE_zungrq_work*.

4.19.2418 LAPACKE_zungtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungtr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_doublecomplex_t *a,
                           armpl_int_t lda,
                           const armpl_doublecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungtr* and *LAPACKE_zungtr*. It also exists with a native Fortran interface as *zungtr*.

4.19.2419 LAPACKE_zungtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zungtr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cungtr_work* and *LAPACKE_zungtr_work*.

4.19.2420 LAPACKE_zunmbr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmbr(armpl_int_t matrix_layout, char vect, char side,
                           char trans, armpl_int_t m, armpl_int_t n,
                           armpl_int_t k, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmbr* and *LAPACKE_zunmbr*. It also exists with a native Fortran interface as *zunmbr*.

4.19.2421 LAPACKE_zunmbr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmbr_work(armpl_int_t matrix_layout, char vect,
                                char side, char trans, armpl_int_t m,
                                armpl_int_t n, armpl_int_t k,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmbr_work* and *LAPACKE_zunmbr_work*.

4.19.2422 LAPACKE_zunmhr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmhr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t ilo,
                           armpl_int_t ihi, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmhr* and *LAPACKE_zunmhr*. It also exists with a native Fortran interface as *zunmhr*.

4.19.2423 LAPACKE_zunmhr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmhr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmhr_work* and *LAPACKE_zunmhr_work*.

4.19.2424 LAPACKE_zunmlq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmlq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmlq* and *LAPACKE_zunmlq*. It also exists with a native Fortran interface as *zunmlq*.

4.19.2425 LAPACKE_zunmlq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmlq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmlq_work* and *LAPACKE_zunmlq_work*.

4.19.2426 LAPACKE_zunmql

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmql(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmql* and *LAPACKE_zunmql*. It also exists with a native Fortran interface as *zunmql*.

4.19.2427 LAPACKE_zunmql_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmql_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmql_work* and *LAPACKE_zunmql_work*.

4.19.2428 LAPACKE_zunmqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmqr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmqr* and *LAPACKE_zunmqr*. It also exists with a native Fortran interface as *zunmqr*.

4.19.2429 LAPACKE_zunmqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmqr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmqr_work* and *LAPACKE_zunmqr_work*.

4.19.2430 LAPACKE_zunmrq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmrq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmrq* and *LAPACKE_zunmrq*. It also exists with a native Fortran interface as *zunmrq*.

4.19.2431 LAPACKE_zunmrq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmrq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
```

(continues on next page)

(continued from previous page)

```
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmrq_work* and *LAPACKE_zunmrq_work*.

4.19.2432 LAPACKE_zunmrz

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmrz(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           armpl_int_t l, const armpl_doublecomplex_t *a,
                           armpl_int_t lda, const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmrz* and *LAPACKE_zunmrz*. It also exists with a native Fortran interface as *zunmrz*.

4.19.2433 LAPACKE_zunmrz_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmrz_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, armpl_int_t l,
                                const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmrz_work* and *LAPACKE_zunmrz_work*.

4.19.2434 LAPACKE_zunmtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmtr(armpl_int_t matrix_layout, char side, char uplo,
                           char trans, armpl_int_t m, armpl_int_t n,
                           const armpl_doublecomplex_t *a, armpl_int_t lda,
                           const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmtr* and *LAPACKE_zunmtr*. It also exists with a native Fortran interface as *zunmtr*.

4.19.2435 LAPACKE_zunmtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zunmtr_work(armpl_int_t matrix_layout, char side,
                                char uplo, char trans, armpl_int_t m,
                                armpl_int_t n, const armpl_doublecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cunmtr_work* and *LAPACKE_zunmtr_work*.

4.19.2436 LAPACKE_zupgtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zupgtr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, const armpl_doublecomplex_t *ap,
                           const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *q, armpl_int_t ldq);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cupgtr* and *LAPACKE_zupgtr*. It also exists with a native Fortran interface as *zupgtr*.

4.19.2437 LAPACKE_zupgtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zupgtr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n,
                                const armpl_doublecomplex_t *ap,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *q, armpl_int_t ldq,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cupgtr_work* and *LAPACKE_zupgtr_work*.

4.19.2438 LAPACKE_zupmtr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zupmtr(armpl_int_t matrix_layout, char side, char uplo,
                           char trans, armpl_int_t m, armpl_int_t n,
                           const armpl_doublecomplex_t *ap,
                           const armpl_doublecomplex_t *tau,
                           armpl_doublecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cupmtr* and *LAPACKE_zupmtr*. It also exists with a native Fortran interface as *zupmtr*.

4.19.2439 LAPACKE_zupmtr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_zupmtr_work(armpl_int_t matrix_layout, char side,
                                char uplo, char trans, armpl_int_t m,
                                armpl_int_t n,
                                const armpl_doublecomplex_t *ap,
                                const armpl_doublecomplex_t *tau,
                                armpl_doublecomplex_t *c, armpl_int_t ldc,
                                armpl_doublecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

CHAPTER

FIVE

FAST FOURIER TRANSFORMS FFTS

5.1 Fast Fourier Transforms FFTs Introduction

For Fast Fourier Transforms Arm Performance Libraries uses the same interface as FFTW3. In addition to the material provided here, users are also referred to the FFTW3 Website for additional documentation:

http://www.fftw.org/fftw3_doc/

FFTW3 support in Arm Performance Libraries currently covers, in C and Fortran, and in single and double precision, the basic, advanced and guru functions with `_dft_` in the function name. In addition, half precision interfaces are provided in C. Half precision support is an extension to the FFTW3 interface which uses fftwh as the prefix for relevant functions and types.

Existing source code calling in to the supported FFTW3 functions need not be modified. Include `fftw3.h` as normal in your source code. Both the single and double precision functions are to be found in one library.

Where plans are not currently supported, i.e. the real-to-real transforms, the interface will return a NULL pointer except for MPI functions. This matches the listed behaviour of FFTW.

Note that since the basic and advanced FFTW interfaces explicitly specify `int` and `unsigned` datatypes then even for ilp64 Arm Performance Libraries the supported FFTW interfaces support only 32-bit integers. For transforms requiring 64-bit integers users are referred to the guru interface.

Behaviour is based on FFTW3 at version 3.3.8.

5.2 How to choose which FFT routine you need

The FFT routines provided in Arm Performance Libraries are grouped into the basic, advanced and guru interfaces. In addition, like all other routines in Arm Performance Libraries they are available in single and double precision and are available in both C and Fortran.

We recommend using the most complicated single call you need to in order to completely describe the set of FFT computations you need to perform, but no more complicated. For instance if the advanced interface covers everything you need, do not use the guru interface. Within Arm Performance Libraries you will be utilising the same high performing algorithms. The basic interface is a small subset of the advanced interface, and the guru interface allows an even greater degree of flexibility over the data layout.

In order to choose the correct routine to use it is useful to understand the different categories:

- Complex-to-complex routines can be applied in both forward and backward directions
- Real-to-complex routines transform real input into complex Hermitian output
- Complex-to-real routines transform from complex Hermitian input to real output

For this discussion we will stick to complex-to-complex functions, although exactly the same rules, with a similar nomenclature, applies for real transforms. Note also that whilst the descriptions talk about “solving FFT problems” the distinction between the interface is all made at the planning stage, with the created plan being the object that is ultimately executed.

5.2.1 The basic interface

In its simplest form the *basic interface* is ideal for cases where a single FFT needs to be solved and the data is all contiguous in memory. This has flavours depending on the number of dimensions, namely *1*-d, *2*-d, *3*-d or *n*-d. The respective plans are *fftw_plan_dft_1d*, *fftw_plan_dft_2d*, *fftw_plan_dft_3d*, and *fftw_plan_dft*.

The *n*-dimensional plan provides us our first layer of abstraction of the interface. For example, plans `p1` and `p2` for a 2-d transform of size 3x4 would be equivalent when made using the following two calls:

C specification:

```
/* Basic interface - 2-d */
p1 = fftw_plan_dft_2d(3, 4, in, out, sign, flags);

/* Basic interface - n-d */
n[0] = 3; n[1] = 4;
p2 = fftw_plan_dft(2, n, in, out, sign, flags);
```

Obviously the n-dimensional interface allows problems with an arbitrary number of dimensions to be solved.

5.2.2 The advanced interface

The *advanced interface* is to be used whenever there are multiple identically sized FFTs to be solved that are laid out regularly in memory, although not necessarily contiguously. The three main options that can be set are:

- Specifying multiple inputs to be solved. In this case, rather than having a loop around calling the basic interface `HOWMANY` times, where the memory distance between input and output cases are given by `IDIST` and `ODIST`, creating a separate plan for each case, you can have a single call to *fftw_plan_many_dft* that creates a single plan.

  This is shown by comparing the following two cases which produce FFT plans on the same data.

  ```
  /* Basic interface */
  for (i=0; i<HOWMANY; i++)
  {
      p3[i] = fftw_plan_dft_2d(3, 4, in[i*IDIST], out[i*ODIST], sign, flags);
  }

  /* Advanced interface */
  p4 = fftw_plan_many_dft(2, n, HOWMANY, in, NULL, 1, IDIST, out, NULL, 1, ODIST,
  ↪ sign, flags);
  ```

- Inputs (and outputs) allow the possibility of 'striding' through memory, meaning that consecutive elements along a dimension might not be adjacent in memory. This is a situation that cannot be handled through the basic interface.

  In the example above the distance between successive elements is 1 for both input (`in`) and output (`out`) arrays, and this is specified as input arguments 6 and 10 respectively. These need not be the same as each other, dependent on your use case.

- The final generalisation allowed in the advanced interface is that the dimensions of each FFT being solved are actually subarrays of a larger memory space. This means that the length of each dimension, `n[i]`, might actually be embedded in a larger memory space. These are given through the parameters `inembed` and `onembed` which define a memory space of `rank` dimensions.

  If the problem to be solved is such that the `inembed[i]==n[i]` for all `i`, then the `inembed` and `onembed` parameters can be passed in as as `NULL`.

5.2.3 The guru interface

The generalisations possible through the advanced interface are further extended using the *guru interface*. The guru interface allows:

1. different strides between data in each dimension
2. the generalisation of the `howmany` data to now be a multidimensional structure
3. the splitting of real and imaginary parts.

Calls to the guru interface introduce the use of an array of structures of type `fftw_iodim`. The precise details of the contents of this structure are explained on the relevant function pages, so are just described at a higher level here.

- The `fftdims` array of structures in *fftw_plan_guru_dft* is of length `rank`, and gives information about the structure of the data stored in that dimension. The three elements stored are

  `n`: the length of the FFT to be performed in that dimension,

  `is`: the stride between successive elements of the input array, and

  `os`: the stride between successive elements of the output array.

- The concept of a multidimensional `howmany` structure is for situations where you are solving multiple FFT transforms where the memory layout is not necessarily in a regular 1-d line, such as with the advanced interface, but you can imagine the start addresses being mapped onto a multi-dimensional grid.

  For example, if you have five sets of four complex-to-complex FFTs to solve, where:

  - each are 3x4 like the example above,
  - the `idist` in the first dimension was 256,
  - the gap between the start of each set of four was 4096,

  then this could be specified as:

```
/* Guru interface for multi-dimensional howmany */

rank = 2;
dims[0].n = 3;    dims[0].is = 4;    dims[0].os = 4;
dims[1].n = 4;    dims[1].is = 1;    dims[1].os = 1;

howmany_rank = 2;
howmany_dims[0].n = 4;    howmany_dims[0].is =  256;    howmany_dims[0].os = ␣
↪256;
howmany_dims[1].n = 5;    howmany_dims[1].is = 4096;    howmany_dims[1].os =␣
↪4096;

p5 = fftw_plan_guru_dft(rank, dims, howmany_rank, howmany_dims, in, out, sign,␣
↪flags);
```

- The splitting of real and imaginary parts mean that if your application has real and imaginary parts of the complex numbers stored separately then their locations can be passed in without having to separately copy them into an interleaved buffer. This is not a situation that can map onto the examples above, however is relatively straightforward to visualize, simply through the addition of two extra arguments passed to the planning call, pointers to the real and imaginary components of the input and output arrays replacing the existing pointers to `in` and `out`.

A final quirk of the guru interface is that if `howmany_dims` is given as 0 then a single FFT will be performed.

5.3 FFT complex to complex functions

5.3.1 fftw_plan_dft

`fftw_plan_dft` is a basic FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft(int rank, const int *n, fftw_complex *in,
                        fftw_complex *out, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft(rank,n,in,out,sign,flags) &
    bind(C, name='fftw_plan_dft')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftw_plan_dft
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 0, `rank-1`

`in` Input parameter

`in` is `fftw_complex*`

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftw_complex*

out is a pointer to a previously allocated array of fftw_complex data. At fftw_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.3.2 fftw_plan_dft_1d

fftw_plan_dft_1d is a basic FFTW interface call for planning a 1-d complex-to-complex FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_1d(int n0, fftw_complex *in, fftw_complex *out,
                           int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_1d(n,in,out,sign,flags) &
    bind(C, name='fftw_plan_dft_1d')
  integer(C_INT), value :: n
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftw_plan_dft_1d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the FFT sequence

Constraint: `n0` >= 1

`in` Input parameter

`in` is `fftw_complex*`

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftw_complex*`

`out` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.3 fftw_plan_dft_2d

`fftw_plan_dft_2d` is a basic FFTW interface call for planning a 2-d complex-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_2d(int n0, int n1, fftw_complex *in,
                           fftw_complex *out, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_2d(n0,n1,in,out,sign,flags) &
    bind(C, name='fftw_plan_dft_2d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftw_plan_dft_2d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`in` Input parameter

`in` is `fftw_complex*`

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

out is fftw_complex

out is a pointer to a previously allocated array of fftw_complex data. At fftw_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.4 fftw_plan_dft_3d

`fftw_plan_dft_3d` is a basic FFTW interface call for planning a 3-d complex-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_3d(int n0, int n1, int n2, fftw_complex *in,
                           fftw_complex *out, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_3d(n0,n1,n2,in,out,sign,flags) &
    bind(C, name='fftw_plan_dft_3d')
```

(continues on next page)

(continued from previous page)

```
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  integer(C_INT), value :: n2
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftw_plan_dft_3d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`n2` Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

`in` Input parameter

`in` is `fftw_complex*`

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftw_complex*`

`out` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.5 fftw_plan_guru_dft

`fftw_plan_guru_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_dft(int rank, const fftw_iodim *dims,
                             int howmany_rank,
                             const fftw_iodim *howmany_dims,
                             fftw_complex *in, fftw_complex *out,
                             int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru_dft(rank,dims,howmany_rank, &
    howmany_dims,in,out,sign,flags) &
    bind(C, name='fftw_plan_guru_dft')
  integer(C_INT), value :: rank
  type(fftw_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim), dimension(*), intent(in) :: howmany_dims
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftw_plan_guru_dft
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftw_iodim *`

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- int n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- int is – the number of memory elements, of type fftw_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- int os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is fftw_complex*

in is a pointer to a previously allocated array of fftw_complex data. At fftw_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftw_complex*

out is a pointer to a previously allocated array of fftw_complex data. At fftw_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.

- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.3.6 fftw_plan_guru_split_dft

fftw_plan_guru_split_dft is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_split_dft(int rank, const fftw_iodim *dims,
                                   int howmany_rank,
                                   const fftw_iodim *howmany_dims,
                                   double *ri, double *ii, double *ro,
                                   double *io, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru_split_dft(rank,dims,howmany_rank, &
    howmany_dims,ri,ii,ro,io,flags) &
    bind(C, name='fftw_plan_guru_split_dft')
  integer(C_INT), value :: rank
  type(fftw_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_DOUBLE), dimension(*), intent(out) :: ri
  real(C_DOUBLE), dimension(*), intent(out) :: ii
  real(C_DOUBLE), dimension(*), intent(out) :: ro
  real(C_DOUBLE), dimension(*), intent(out) :: io
  integer(C_INT), value :: flags
end function fftw_plan_guru_split_dft
```

Returns

An fftw_plan object is returned that can be used in subsequent *fftw_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftw_execute_dft*().

Parameters

rank Input parameter

rank is int

The number of dimensions of each individual FFT problem to be solved.

Constraint: rank >= 1

dims Input parameter

dims is const fftw_iodim *

dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- int n – the length of the i th dimension.
- int is – the stride between successive elements in the input vector in the i th dimension.
- int os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: dims.n[i] >= 1 for i in 0, rank-1

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftw_iodim *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- int n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- int is – the number of memory elements, of type fftw_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- int os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

ri Input parameter

ri is double *

ri is a pointer to a previously allocated array of double data. At fftw_execute() time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ii Input parameter

ii is double *

ii is a pointer to a previously allocated array of double data. At fftw_execute() time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

ro is double *

ro is a pointer to a previously allocated array of double data. At fftw_execute() time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

io is double *

io is a pointer to a previously allocated array of double data. At fftw_execute() time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.7 fftw_plan_guru64_dft

`fftw_plan_guru64_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftw_plan_guru_dft*, `fftw_plan_guru64_dft` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru64_dft(int rank, const fftw_iodim64 *dims,
                               int howmany_rank,
                               const fftw_iodim64 *howmany_dims,
                               fftw_complex *in, fftw_complex *out,
                               int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru64_dft(rank,dims,howmany_rank, &
    howmany_dims,in,out,sign,flags) &
    bind(C, name='fftw_plan_guru64_dft')
  integer(C_INT), value :: rank
  type(fftw_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim64), dimension(*), intent(in) :: howmany_dims
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftw_plan_guru64_dft
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftw_iodim64 *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t is` – the number of memory elements, of type `fftw_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `fftw_complex*`

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftw_complex*`

`out` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.8 fftw_plan_guru64_split_dft

`fftw_plan_guru64_split_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Unlike *fftw_plan_guru_split_dft*, `fftw_plan_guru64_split_dft` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_split_dft(int rank, const fftw_iodim64 *dims,
                                   int howmany_rank,
                                   const fftw_iodim64 *howmany_dims,
                                   double *ri, double *ii, double *ro,
                                   double *io, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru64_split_dft(rank,dims,howmany_rank, &
    howmany_dims,ri,ii,ro,io,flags) &
    bind(C, name='fftw_plan_guru64_split_dft')
  integer(C_INT), value :: rank
  type(fftw_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim64), dimension(*), intent(in) :: howmany_dims
  real(C_DOUBLE), dimension(*), intent(out) :: ri
  real(C_DOUBLE), dimension(*), intent(out) :: ii
  real(C_DOUBLE), dimension(*), intent(out) :: ro
  real(C_DOUBLE), dimension(*), intent(out) :: io
  integer(C_INT), value :: flags
end function fftw_plan_guru64_split_dft
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftw_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftw_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

ri Input parameter

ri is double *

ri is a pointer to a previously allocated array of double data. At fftw_execute() time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ii Input parameter

ri is double *

ri is a pointer to a previously allocated array of double data. At fftw_execute() time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

ro is double *

ro is a pointer to a previously allocated array of double data. At fftw_execute() time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

io is double *

io is a pointer to a previously allocated array of double data. At fftw_execute() time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.9 fftw_plan_many_dft

`fftw_plan_many_dft` is an advanced FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on `howmany` sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

For more information on the use of advanced planning calls see *How to choose which FFT routine you need*.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_many_dft(int rank, const int *n, int howmany,
                             fftw_complex *in, const int *inembed,
                             int istride, int idist, fftw_complex *out,
                             const int *onembed, int ostride,
                             int odist, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_many_dft(rank,n,howmany,in,inembed, &
    istride,idist,out,onembed,ostride,odist,sign,flags) &
    bind(C, name='fftw_plan_many_dft')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  integer(C_INT), value :: howmany
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  integer(C_INT), dimension(*), intent(in) :: inembed
  integer(C_INT), value :: istride
  integer(C_INT), value :: idist
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), dimension(*), intent(in) :: onembed
  integer(C_INT), value :: ostride
  integer(C_INT), value :: odist
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftw_plan_many_dft
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 0, `rank-1`

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

in Input parameter

in is fftw_complex*

in is a pointer to a previously allocated array of fftw_complex data. At fftw_execute() time this will have been filled with the input sequence on which to perform the FFT.. The input data for set k starts at address in+k*idist.

Storage: Data in arrays will be stored in row-major order.

inembed Input parameter

inembed is const int

inembed is an array of dimension [rank] or NULL This array denotes the dimensionality of a potentially larger space of which the input array, in, dimensions given by n, is a sub array.

Constraint: Either inembed[i] >= n[i] for i in 0, rank-1 OR if inembed == NULL, then inembed is assumed to have the same dimensions as n

istride Input parameter

istride is int

istride is the distance between successive elements of the input data

idist Input parameter

idist is int

idist is the distance between the start of each of the howmany transforms in the input data

out Input parameter

out is fftw_complex*

out is a pointer to a previously allocated array of fftw_complex data. At fftw_execute() time this will be filled with the resulting transform coefficients. The output data for set k starts at address out+k*odist.

Storage: Data in arrays will be stored in row-major order.

onembed Input parameter

onembed is const int

onembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, out, dimensions given by n, is a sub array.

Constraint: Either onembed[i] >= n[i] for i in 0, rank-1 OR if onembed == NULL, then onembed is assumed to have the same dimensions as n

ostride Input parameter

ostride is int

ostride is the distance between successive elements of the output data

odist Input parameter

odist is int

odist is the distance between the start of each of the howmany transforms in the output data

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for forward transform,

sign = 1 (FFTW_BACKWARD) for backwards transform

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.10 fftwf_plan_dft

`fftwf_plan_dft` is a basic FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft(int rank, const int *n, fftwf_complex *in,
                          fftwf_complex *out, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft(rank,n,in,out,sign,flags) &
    bind(C, name='fftwf_plan_dft')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftwf_plan_dft
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 0, `rank-1`

`in` Input parameter

`in` is `fftwf_complex*`

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwf_complex*`

`out` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.3.11 fftwf_plan_dft_1d

fftwf_plan_dft_1d is a basic FFTW interface call for planning a 1-d complex-to-complex FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_1d(int n0, fftwf_complex *in, fftwf_complex *out,
                             int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_1d(n,in,out,sign,flags) &
    bind(C, name='fftwf_plan_dft_1d')
  integer(C_INT), value :: n
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftwf_plan_dft_1d
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the FFT sequence

Constraint: `n0` >= 1

`in` Input parameter

`in` is `fftwf_complex*`

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwf_complex*`

`out` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.

- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.3.12 fftwf_plan_dft_2d

fftwf_plan_dft_2d is a basic FFTW interface call for planning a 2-d complex-to-complex FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_2d(int n0, int n1, fftwf_complex *in,
                             fftwf_complex *out, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_2d(n0,n1,in,out,sign,flags) &
    bind(C, name='fftwf_plan_dft_2d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftwf_plan_dft_2d
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`in` Input parameter

`in` is `fftwf_complex*`

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

out is fftwf_complex

out is a pointer to a previously allocated array of fftwf_complex data. At fftwf_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.

- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.3.13 fftwf_plan_dft_3d

fftwf_plan_dft_3d is a basic FFTW interface call for planning a 3-d complex-to-complex FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_3d(int n0, int n1, int n2, fftwf_complex *in,
                             fftwf_complex *out, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_3d(n0,n1,n2,in,out,sign,flags) &
    bind(C, name='fftwf_plan_dft_3d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  integer(C_INT), value :: n2
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftwf_plan_dft_3d
```

Returns

This function returns an fftwf_plan object that can be used in subsequent *fftwf_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftwf_execute_dft*().

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

n1 Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

n2 Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

in Input parameter

`in` is `fftwf_complex*`

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `fftwf_complex*`

`out` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.

- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.14 fftwf_plan_guru_dft

`fftwf_plan_guru_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_dft(int rank, const fftwf_iodim *dims,
                               int howmany_rank,
                               const fftwf_iodim *howmany_dims,
                               fftwf_complex *in, fftwf_complex *out,
                               int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru_dft(rank,dims,howmany_rank, &
    howmany_dims,in,out,sign,flags) &
    bind(C, name='fftwf_plan_guru_dft')
  integer(C_INT), value :: rank
  type(fftwf_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim), dimension(*), intent(in) :: howmany_dims
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftwf_plan_guru_dft
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwf_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftwf_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

in Input parameter

in is fftwf_complex*

in is a pointer to a previously allocated array of fftwf_complex data. At fftwf_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwf_complex*

out is a pointer to a previously allocated array of fftwf_complex data. At fftwf_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.3.15 fftwf_plan_guru_split_dft

`fftwf_plan_guru_split_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_split_dft(int rank, const fftwf_iodim *dims,
                                     int howmany_rank,
                                     const fftwf_iodim *howmany_dims,
                                     float *ri, float *ii, float *ro,
                                     float *io, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru_split_dft(rank,dims,howmany_rank, &
    howmany_dims,ri,ii,ro,io,flags) &
    bind(C, name='fftwf_plan_guru_split_dft')
  integer(C_INT), value :: rank
  type(fftwf_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_FLOAT), dimension(*), intent(out) :: ri
  real(C_FLOAT), dimension(*), intent(out) :: ii
  real(C_FLOAT), dimension(*), intent(out) :: ro
  real(C_FLOAT), dimension(*), intent(out) :: io
  integer(C_INT), value :: flags
end function fftwf_plan_guru_split_dft
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.

- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

howmany_rank Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

`howmany_dims` is `const fftwf_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftwf_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

ri Input parameter

`ri` is `float *`

`ri` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ii Input parameter

`ii` is `float *`

`ii` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

`ro` is `float *`

`ro` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

`io` is `float *`

`io` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.16 fftwf_plan_guru64_dft

`fftwf_plan_guru64_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftwf_plan_guru_dft*, `fftwf_plan_guru64_dft` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru64_dft(int rank, const fftwf_iodim64 *dims,
                                 int howmany_rank,
                                 const fftwf_iodim64 *howmany_dims,
                                 fftwf_complex *in, fftwf_complex *out,
                                 int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru64_dft(rank,dims,howmany_rank, &
    howmany_dims,in,out,sign,flags) &
    bind(C, name='fftwf_plan_guru64_dft')
  integer(C_INT), value :: rank
  type(fftwf_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim64), dimension(*), intent(in) :: howmany_dims
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftwf_plan_guru64_dft
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwf_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftwf_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is fftwf_complex*

in is a pointer to a previously allocated array of fftwf_complex data. At fftwf_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwf_complex*

out is a pointer to a previously allocated array of fftwf_complex data. At fftwf_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.17 fftwf_plan_guru64_split_dft

`fftwf_plan_guru64_split_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Unlike *fftwf_plan_guru_split_dft*, `fftwf_plan_guru64_split_dft` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_split_dft(int rank, const fftwf_iodim64 *dims,
                                     int howmany_rank,
                                     const fftwf_iodim64 *howmany_dims,
                                     float *ri, float *ii, float *ro,
                                     float *io, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'
```

(continues on next page)

(continued from previous page)

```
type(C_PTR) function fftwf_plan_guru64_split_dft(rank,dims, &
    howmany_rank,howmany_dims,ri,ii,ro,io,flags) &
    bind(C, name='fftwf_plan_guru64_split_dft')
  integer(C_INT), value :: rank
  type(fftwf_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim64), dimension(*), intent(in) :: howmany_dims
  real(C_FLOAT), dimension(*), intent(out) :: ri
  real(C_FLOAT), dimension(*), intent(out) :: ii
  real(C_FLOAT), dimension(*), intent(out) :: ro
  real(C_FLOAT), dimension(*), intent(out) :: io
  integer(C_INT), value :: flags
end function fftwf_plan_guru64_split_dft
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwf_iodim64 *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t is` – the number of memory elements, of type `fftwf_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

ri Input parameter

`ri` is `float *`

`ri` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ii Input parameter

`ri` is `float *`

`ri` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

`ro` is `float *`

`ro` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

`io` is `float *`

`io` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.

- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.18 fftwf_plan_many_dft

`fftwf_plan_many_dft` is an advanced FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on `howmany` sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

For more information on the use of advanced planning calls see *How to choose which FFT routine you need*.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_many_dft(int rank, const int *n, int howmany,
                               fftwf_complex *in, const int *inembed,
                               int istride, int idist, fftwf_complex *out,
                               const int *onembed, int ostride,
                               int odist, int sign, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_many_dft(rank,n,howmany,in,inembed, &
    istride,idist,out,onembed,ostride,odist,sign,flags) &
    bind(C, name='fftwf_plan_many_dft')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  integer(C_INT), value :: howmany
```

(continues on next page)

(continued from previous page)

```
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  integer(C_INT), dimension(*), intent(in) :: inembed
  integer(C_INT), value :: istride
  integer(C_INT), value :: idist
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), dimension(*), intent(in) :: onembed
  integer(C_INT), value :: ostride
  integer(C_INT), value :: odist
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftwf_plan_many_dft
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 0, `rank-1`

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

`in` Input parameter

`in` is `fftwf_complex*`

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.. The input data for set `k` starts at address `in+k*idist`.

Storage: Data in arrays will be stored in row-major order.

`inembed` Input parameter

`inembed` is `const int`

`inembed` is an array of dimension `[rank]` or `NULL` This array denotes the dimensionality of a potentially larger space of which the input array, `in`, dimensions given by `n`, is a sub array.

Constraint: Either `inembed[i]` >= `n[i]` for `i` in 0, `rank-1` OR if `inembed` == `NULL`, then `inembed` is assumed to have the same dimensions as `n`

istride Input parameter

istride is int

istride is the distance between successive elements of the input data

idist Input parameter

idist is int

idist is the distance between the start of each of the howmany transforms in the input data

out Input parameter

out is fftwf_complex*

out is a pointer to a previously allocated array of fftwf_complex data. At fftwf_execute() time this will be filled with the resulting transform coefficients. The output data for set k starts at address out+k*odist.

Storage: Data in arrays will be stored in row-major order.

onembed Input parameter

onembed is const int

onembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, out, dimensions given by n, is a sub array.

Constraint: Either onembed[i] >= n[i] for i in 0, rank-1 OR if onembed == NULL, then onembed is assumed to have the same dimensions as n

ostride Input parameter

ostride is int

ostride is the distance between successive elements of the output data

odist Input parameter

odist is int

odist is the distance between the start of each of the howmany transforms in the output data

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for forward transform,

sign = 1 (FFTW_BACKWARD) for backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.

- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.19 fftwh_plan_dft

`fftwh_plan_dft` is a basic FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft(int rank, const int *n, fftwh_complex *in,
                          fftwh_complex *out, int sign, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 0, `rank-1`

`in` Input parameter

`in` is `fftwh_complex*`

`in` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwh_complex*`

`out` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.20 fftwh_plan_dft_1d

`fftwh_plan_dft_1d` is a basic FFTW interface call for planning a 1-d complex-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_1d(int n0, fftwh_complex *in, fftwh_complex *out,
                             int sign, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the FFT sequence

Constraint: `n0` >= 1

`in` Input parameter

`in` is `fftwh_complex*`

`in` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwh_complex*`

`out` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.21 fftwh_plan_dft_2d

`fftwh_plan_dft_2d` is a basic FFTW interface call for planning a 2-d complex-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_2d(int n0, int n1, fftwh_complex *in,
                             fftwh_complex *out, int sign, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

n0 Input parameter

n0 is int

This is the length of the first dimension of the FFT sequence

Constraint: n0 >= 1

n1 Input parameter

n1 is int

This is the length of the second dimension of the FFT sequence

Constraint: n1 >= 1

in Input parameter

in is fftwh_complex*

in is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwh_complex

out is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.

- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.22 fftwh_plan_dft_3d

`fftwh_plan_dft_3d` is a basic FFTW interface call for planning a 3-d complex-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_3d(int n0, int n1, int n2, fftwh_complex *in,
                             fftwh_complex *out, int sign, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`n2` Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

`in` Input parameter

`in` is `fftwh_complex*`

`in` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwh_complex*`

`out` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`sign` Input parameter

`sign` is `int`

`sign` is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: `sign` = -1 (`FFTW_FORWARD`) for a forward transform,

`sign` = 1 (`FFTW_BACKWARD`) for a backwards transform

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.23 fftwh_plan_guru_dft

`fftwh_plan_guru_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_dft(int rank, const fftwh_iodim *dims,
                               int howmany_rank,
                               const fftwh_iodim *howmany_dims,
                               fftwh_complex *in, fftwh_complex *out,
                               int sign, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwh_iodim *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- int n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- int is – the number of memory elements, of type fftwh_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- int os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is fftwh_complex*

in is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwh_complex*

out is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.

- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.24 fftwh_plan_guru_split_dft

`fftwh_plan_guru_split_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_split_dft(int rank, const fftwh_iodim *dims,
                                     int howmany_rank,
                                     const fftwh_iodim *howmany_dims,
                                     __fp16 *ri, __fp16 *ii, __fp16 *ro,
                                     __fp16 *io, int sign, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwh_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftwh_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`ri` Input parameter

`ri` is `__fp16 *`

`ri` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`ii` Input parameter

`ii` is `__fp16 *`

`ii` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`ro` Input parameter

`ro` is `__fp16 *`

`ro` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

io is __fp16 *

io is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.3.25 fftwh_plan_guru64_dft

fftwh_plan_guru64_dft is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftwh_plan_guru_dft*, `fftwh_plan_guru64_dft` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru64_dft(int rank, const fftwh_iodim64 *dims,
                                 int howmany_rank,
                                 const fftwh_iodim64 *howmany_dims,
                                 fftwh_complex *in, fftwh_complex *out,
                                 int sign, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwh_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftwh_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is fftwh_complex*

in is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwh_complex*

out is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.

- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.3.26 fftwh_plan_guru64_split_dft

`fftwh_plan_guru64_split_dft` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Unlike *fftwh_plan_guru_split_dft*, `fftwh_plan_guru64_split_dft` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_split_dft(int rank, const fftwh_iodim64 *dims,
                                     int howmany_rank,
                                     const fftwh_iodim64 *howmany_dims,
                                     __fp16 *ri, __fp16 *ii, __fp16 *ro,
                                     __fp16 *io, int sign, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

dims Input parameter

dims is const fftwh_iodim64 *

dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the length of the i th dimension.
- ptrdiff_t is – the stride between successive elements in the input vector in the i th dimension.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: dims.n[i] >= 1 for i in 0, rank-1

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwh_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftwh_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

ri Input parameter

ri is __fp16 *

ri is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ii Input parameter

ri is __fp16 *

ri is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

ro is __fp16 *

ro is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

io is __fp16 *

io is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for a forward transform,

sign = 1 (FFTW_BACKWARD) for a backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.3.27 fftwh_plan_many_dft

`fftwh_plan_many_dft` is an advanced FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on `howmany` sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

For more information on the use of advanced planning calls see *How to choose which FFT routine you need*.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_many_dft(int rank, const int *n, int howmany,
                               fftwh_complex *in, const int *inembed,
                               int istride, int idist, fftwh_complex *out,
                               const int *onembed, int ostride,
                               int odist, int sign, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 0, `rank-1`

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

`in` Input parameter

`in` is `fftwh_complex*`

`in` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.. The input data for set `k` starts at address `in+k*idist`.

Storage: Data in arrays will be stored in row-major order.

inembed Input parameter

inembed is const int

inembed is an array of dimension [rank] or NULL This array denotes the dimensionality of a potentially larger space of which the input array, in, dimensions given by n, is a sub array.

Constraint: Either inembed[i] >= n[i] for i in 0, rank-1 OR if inembed == NULL, then inembed is assumed to have the same dimensions as n

istride Input parameter

istride is int

istride is the distance between successive elements of the input data

idist Input parameter

idist is int

idist is the distance between the start of each of the howmany transforms in the input data

out Input parameter

out is fftwh_complex*

out is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will be filled with the resulting transform coefficients. The output data for set k starts at address out+k*odist.

Storage: Data in arrays will be stored in row-major order.

onembed Input parameter

onembed is const int

onembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, out, dimensions given by n, is a sub array.

Constraint: Either onembed[i] >= n[i] for i in 0, rank-1 OR if onembed == NULL, then onembed is assumed to have the same dimensions as n

ostride Input parameter

ostride is int

ostride is the distance between successive elements of the output data

odist Input parameter

odist is int

odist is the distance between the start of each of the howmany transforms in the output data

sign Input parameter

sign is int

sign is an integer denoting whether a forward or backward FFT transform should be performed

Constraint: sign = -1 (FFTW_FORWARD) for forward transform,

sign = 1 (FFTW_BACKWARD) for backwards transform

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.

- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4 FFT real to complex functions

5.4.1 fftw_plan_dft_r2c

`fftw_plan_dft_r2c` is a basic FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_r2c(int rank, const int *n, double *in,
                            fftw_complex *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_r2c(rank,n,in,out,flags) &
    bind(C, name='fftw_plan_dft_r2c')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
```

(continues on next page)

(continued from previous page)

```
  real(C_DOUBLE), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_dft_r2c
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is a `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >=1 for i in 1, rank

`in` Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftw_complex*`

`out` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.

- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.4.2 fftw_plan_dft_r2c_1d

fftw_plan_dft_r2c_1d is a basic FFTW interface call for planning a 1-d real-to-complex FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_r2c_1d(int n0, double *in, fftw_complex *out,
                               unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_r2c_1d(n,in,out,flags) &
    bind(C, name='fftw_plan_dft_r2c_1d')
  integer(C_INT), value :: n
  real(C_DOUBLE), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_dft_r2c_1d
```

Returns

An fftw_plan object is returned that can be used in subsequent *fftw_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftw_execute_dft_r2c*().

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the FFT sequence

Constraint: `n0` >= 1

in Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `fftw_complex*`

`out` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.3 fftw_plan_dft_r2c_2d

`fftw_plan_dft_r2c_2d` is a basic FFTW interface call for planning a 2-d real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_r2c_2d(int n0, int n1, double *in,
                               fftw_complex *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_r2c_2d(n0,n1,in,out,flags) &
    bind(C, name='fftw_plan_dft_r2c_2d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  real(C_DOUBLE), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_dft_r2c_2d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_r2c* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`in` Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is fftw_complex

`out` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.4 fftw_plan_dft_r2c_3d

`fftw_plan_dft_r2c_3d` is a basic FFTW interface call for planning a 3-d real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_r2c_3d(int n0, int n1, int n2, double *in,
                               fftw_complex *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_r2c_3d(n0,n1,n2,in,out,flags) &
    bind(C, name='fftw_plan_dft_r2c_3d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  integer(C_INT), value :: n2
  real(C_DOUBLE), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_dft_r2c_3d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_r2c* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`n2` Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

`in` Input parameter

`in` is double

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftw_complex*`

`out` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.5 fftw_plan_guru_dft_r2c

`fftw_plan_guru_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_dft_r2c(int rank, const fftw_iodim *dims,
                                 int howmany_rank,
                                 const fftw_iodim *howmany_dims,
                                 double *in, fftw_complex *out,
                                 unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru_dft_r2c(rank,dims,howmany_rank, &
    howmany_dims,in,out,flags) &
    bind(C, name='fftw_plan_guru_dft_r2c')
  integer(C_INT), value :: rank
  type(fftw_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_DOUBLE), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_guru_dft_r2c
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftw_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftw_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftw_complex*`

`out` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.6 fftw_plan_guru_split_dft_r2c

`fftw_plan_guru_split_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_split_dft_r2c(int rank, const fftw_iodim *dims,
                                       int howmany_rank,
                                       const fftw_iodim *howmany_dims,
                                       double *in, double *ro,
                                       double *io, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru_split_dft_r2c(rank,dims, &
    howmany_rank,howmany_dims,in,ro,io,flags) &
    bind(C, name='fftw_plan_guru_split_dft_r2c')
  integer(C_INT), value :: rank
  type(fftw_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_DOUBLE), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: ro
  real(C_DOUBLE), dimension(*), intent(out) :: io
  integer(C_INT), value :: flags
end function fftw_plan_guru_split_dft_r2c
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_r2c*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

howmany_rank Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

`howmany_dims` is `const fftw_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftw_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

in Input parameter

`in` is `double *`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

`ro` is `double *`

`ro` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

`io` is `double *`

`io` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.7 fftw_plan_guru64_dft_r2c

`fftw_plan_guru64_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftw_plan_guru_dft_r2c*, `fftw_plan_guru64_dft_r2c` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru64_dft_r2c(int rank, const fftw_iodim64 *dims,
                                   int howmany_rank,
```

(continues on next page)

(continued from previous page)

```
                                    const fftw_iodim64 *howmany_dims,
                                    double *in, fftw_complex *out,
                                    unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru64_dft_r2c(rank,dims,howmany_rank, &
    howmany_dims,in,out,flags) &
    bind(C, name='fftw_plan_guru64_dft_r2c')
  integer(C_INT), value :: rank
  type(fftw_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim64), dimension(*), intent(in) :: howmany_dims
  real(C_DOUBLE), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_guru64_dft_r2c
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftw_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftw_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is double*

in is a pointer to a previously allocated array of double data. At fftw_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftw_complex*

out is a pointer to a previously allocated array of fftw_complex data. At fftw_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.

- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.8 fftw_plan_guru64_split_dft_r2c

`fftw_plan_guru64_split_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Unlike *fftw_plan_guru_split_dft_r2c*, `fftw_plan_guru64_split_dft_r2c` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_split_dft_r2c(int rank, const fftw_iodim64 *dims,
                                       int howmany_rank,
                                       const fftw_iodim64 *howmany_dims,
                                       double *in, double *ro,
                                       double *io, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru64_split_dft_r2c(rank,dims,howmany_rank,howmany_
↪dims,in,ro,io,flags) &
                     bind(C, name='fftw_plan_guru64_split_dft_r2c')
  integer(C_INT), value :: rank
  type(fftw_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim64), dimension(*), intent(in) :: howmany_dims
  real(C_DOUBLE), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: ro
  real(C_DOUBLE), dimension(*), intent(out) :: io
  integer(C_INT), value :: flags
end function fftw_plan_guru64_split_dft_r2c
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_r2c*`()`.

Parameters

rank Input parameter

rank is int

The number of dimensions of each individual FFT problem to be solved.

Constraint: rank >= 1

dims Input parameter

dims is const fftw_iodim64 *

dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the length of the i th dimension.
- ptrdiff_t is – the stride between successive elements in the input vector in the i th dimension.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: dims.n[i] >= 1 for i in 0, rank-1

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftw_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftw_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is double *

in is a pointer to a previously allocated array of double data. At fftw_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

ro is double *

ro is a pointer to a previously allocated array of double data. At fftw_execute() time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

io is double *

io is a pointer to a previously allocated array of double data. At fftw_execute() time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.4.9 fftw_plan_many_dft_r2c

fftw_plan_many_dft_r2c is an advanced FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on howmany sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

For more information on the use of advanced planning calls see *How to choose which FFT routine you need*.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_many_dft_r2c(int rank, const int *n, int howmany,
                                 double *in, const int *inembed,
                                 int istride, int idist, fftw_complex *out,
                                 const int *onembed, int ostride, int odist,
                                 unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_many_dft_r2c(rank,n,howmany,in,inembed, &
    istride,idist,out,onembed,ostride,odist,flags) &
    bind(C, name='fftw_plan_many_dft_r2c')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  integer(C_INT), value :: howmany
  real(C_DOUBLE), dimension(*), intent(out) :: in
  integer(C_INT), dimension(*), intent(in) :: inembed
  integer(C_INT), value :: istride
  integer(C_INT), value :: idist
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), dimension(*), intent(in) :: onembed
  integer(C_INT), value :: ostride
  integer(C_INT), value :: odist
  integer(C_INT), value :: flags
end function fftw_plan_many_dft_r2c
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is `const int`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, rank

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: howmany >= 1

in Input parameter

in is double*

in is a pointer to a previously allocated array of double data. At fftw_execute() time this will have been filled with the input sequence on which to perform the FFT. The input data for set k starts at address in+k*idist.

Storage: Data in arrays will be stored in row-major order.

inembed Input parameter

inembed is const int

inembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, in, dimensions given by n, is a sub array.

Constraint: Either inembed[i] >= n[i] for i in 0, rank-1 OR if inembed == NULL, then inembed is assumed to have the same dimensions as n

istride Input parameter

istride is int

istride is the distance between successive elements of the input data

idist Input parameter

idist is int

idist is the distance between the start of each of the howmany transforms in the input data

out Input parameter

out is fftw_complex*

out is a pointer to a previously allocated array of fftw_complex data. At fftw_execute() time this will be filled with the resulting transform coefficients The output data for set k starts at address out+k*odist.

Storage: Data in arrays will be stored in row-major order.

onembed Input parameter

onembed is const int

onembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, out, dimensions given by n, is a sub array.

Constraint: Either onembed[i] >= n[i] for i in 0, rank-1 OR if onembed == NULL, then onembed is assumed to have the same dimensions as n

ostride Input parameter

ostride is int

ostride is the distance between successive elements of the output data

odist Input parameter

odist is int

odist is the distance between the start of each of the howmany transforms in the output data

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.10 fftwf_plan_dft_r2c

`fftwf_plan_dft_r2c` is a basic FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_r2c(int rank, const int *n, float *in,
                              fftwf_complex *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_r2c(rank,n,in,out,flags) &
    bind(C, name='fftwf_plan_dft_r2c')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  real(C_FLOAT), dimension(*), intent(out) :: in
```

(continues on next page)

(continued from previous page)

```
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_dft_r2c
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is a `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >=1 for i in 1, rank

`in` Input parameter

`in` is `float`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwf_complex*`

`out` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.

- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.4.11 fftwf_plan_dft_r2c_1d

fftwf_plan_dft_r2c_1d is a basic FFTW interface call for planning a 1-d real-to-complex FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_r2c_1d(int n0, float *in, fftwf_complex *out,
                                 unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_r2c_1d(n,in,out,flags) &
    bind(C, name='fftwf_plan_dft_r2c_1d')
  integer(C_INT), value :: n
  real(C_FLOAT), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_dft_r2c_1d
```

Returns

This function returns an fftwf_plan object that can be used in subsequent *fftwf_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftwf_execute_dft_r2c*().

Parameters

n0 Input parameter

n0 is int

This is the length of the FFT sequence

Constraint: n0 >= 1

in Input parameter

in is float

in is a pointer to a previously allocated array of float data. At fftwf_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwf_complex*

out is a pointer to a previously allocated array of fftwf_complex data. At fftwf_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.4.12 fftwf_plan_dft_r2c_2d

`fftwf_plan_dft_r2c_2d` is a basic FFTW interface call for planning a 2-d real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_r2c_2d(int n0, int n1, float *in,
                                 fftwf_complex *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_r2c_2d(n0,n1,in,out,flags) &
    bind(C, name='fftwf_plan_dft_r2c_2d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  real(C_FLOAT), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_dft_r2c_2d
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_r2c*`()`.

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

n1 Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

in Input parameter

`in` is `float`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is fftwf_complex

`out` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.13 fftwf_plan_dft_r2c_3d

`fftwf_plan_dft_r2c_3d` is a basic FFTW interface call for planning a 3-d real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_r2c_3d(int n0, int n1, int n2, float *in,
                                 fftwf_complex *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_r2c_3d(n0,n1,n2,in,out,flags) &
    bind(C, name='fftwf_plan_dft_r2c_3d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  integer(C_INT), value :: n2
  real(C_FLOAT), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_dft_r2c_3d
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_r2c* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`n2` Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

`in` Input parameter

`in` is float

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwf_complex*`

`out` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.14 fftwf_plan_guru_dft_r2c

`fftwf_plan_guru_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_dft_r2c(int rank, const fftwf_iodim *dims,
                                   int howmany_rank,
                                   const fftwf_iodim *howmany_dims,
                                   float *in, fftwf_complex *out,
                                   unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru_dft_r2c(rank,dims,howmany_rank, &
    howmany_dims,in,out,flags) &
    bind(C, name='fftwf_plan_guru_dft_r2c')
  integer(C_INT), value :: rank
  type(fftwf_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_FLOAT), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_guru_dft_r2c
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwf_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftwf_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `float`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwf_complex*`

`out` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.15 fftwf_plan_guru_split_dft_r2c

`fftwf_plan_guru_split_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_split_dft_r2c(int rank, const fftwf_iodim *dims,
                                         int howmany_rank,
                                         const fftwf_iodim *howmany_dims,
                                         float *in, float *ro,
                                         float *io, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru_split_dft_r2c(rank,dims, &
    howmany_rank,howmany_dims,in,ro,io,flags) &
    bind(C, name='fftwf_plan_guru_split_dft_r2c')
  integer(C_INT), value :: rank
  type(fftwf_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_FLOAT), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: ro
  real(C_FLOAT), dimension(*), intent(out) :: io
  integer(C_INT), value :: flags
end function fftwf_plan_guru_split_dft_r2c
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

howmany_rank Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

`howmany_dims` is `const fftwf_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftwf_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

in Input parameter

`in` is `float *`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

`ro` is `float *`

`ro` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

`io` is `float *`

`io` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.16 fftwf_plan_guru64_dft_r2c

`fftwf_plan_guru64_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftwf_plan_guru_dft_r2c*, `fftwf_plan_guru64_dft_r2c` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru64_dft_r2c(int rank, const fftwf_iodim64 *dims,
                                     int howmany_rank,
```

(continues on next page)

(continued from previous page)

```
                                    const fftwf_iodim64 *howmany_dims,
                                    float *in, fftwf_complex *out,
                                    unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru64_dft_r2c(rank,dims,howmany_rank, &
    howmany_dims,in,out,flags) &
    bind(C, name='fftwf_plan_guru64_dft_r2c')
  integer(C_INT), value :: rank
  type(fftwf_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim64), dimension(*), intent(in) :: howmany_dims
  real(C_FLOAT), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_guru64_dft_r2c
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwf_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftwf_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is float

in is a pointer to a previously allocated array of float data. At fftwf_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwf_complex*

out is a pointer to a previously allocated array of fftwf_complex data. At fftwf_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.

- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.17 fftwf_plan_guru64_split_dft_r2c

`fftwf_plan_guru64_split_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Unlike *fftwf_plan_guru_split_dft_r2c*, `fftwf_plan_guru64_split_dft_r2c` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_split_dft_r2c(int rank, const fftwf_iodim64 *dims,
                                         int howmany_rank,
                                         const fftwf_iodim64 *howmany_dims,
                                         float *in, float *ro,
                                         float *io, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru64_split_dft_r2c(rank,dims, &
    howmany_rank,howmany_dims,in,ro,io,flags) &
    bind(C, name='fftwf_plan_guru64_split_dft_r2c')
  integer(C_INT), value :: rank
  type(fftwf_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim64), dimension(*), intent(in) :: howmany_dims
  real(C_FLOAT), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: ro
  real(C_FLOAT), dimension(*), intent(out) :: io
  integer(C_INT), value :: flags
end function fftwf_plan_guru64_split_dft_r2c
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_r2c* `()`.

Parameters

rank Input parameter

rank is int

The number of dimensions of each individual FFT problem to be solved.

Constraint: rank >= 1

dims Input parameter

dims is const fftwf_iodim64 *

dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the length of the i th dimension.
- ptrdiff_t is – the stride between successive elements in the input vector in the i th dimension.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: dims.n[i] >= 1 for i in 0, rank-1

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwf_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftwf_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is float *

in is a pointer to a previously allocated array of float data. At fftwf_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

ro is float *

ro is a pointer to a previously allocated array of float data. At fftwf_execute() time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

io is float *

io is a pointer to a previously allocated array of float data. At fftwf_execute() time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.4.18 fftwf_plan_many_dft_r2c

fftwf_plan_many_dft_r2c is an advanced FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on howmany sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

For more information on the use of advanced planning calls see *How to choose which FFT routine you need*.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_many_dft_r2c(int rank, const int *n, int howmany,
                                   float *in, const int *inembed,
                                   int istride, int idist, fftwf_complex *out,
                                   const int *onembed, int ostride, int odist,
                                   unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_many_dft_r2c(rank,n,howmany,in,inembed, &
    istride,idist,out,onembed,ostride,odist,flags) &
    bind(C, name='fftwf_plan_many_dft_r2c')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  integer(C_INT), value :: howmany
  real(C_FLOAT), dimension(*), intent(out) :: in
  integer(C_INT), dimension(*), intent(in) :: inembed
  integer(C_INT), value :: istride
  integer(C_INT), value :: idist
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), dimension(*), intent(in) :: onembed
  integer(C_INT), value :: ostride
  integer(C_INT), value :: odist
  integer(C_INT), value :: flags
end function fftwf_plan_many_dft_r2c
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_r2c*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is `const int`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, rank

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

`in` Input parameter

`in` is `float`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT. The input data for set `k` starts at address `in+k*idist`.

Storage: Data in arrays will be stored in row-major order.

`inembed` Input parameter

`inembed` is `const int`

`inembed` is an array of dimension `[rank]` or `NULL`. This array denotes the dimensionality of a potentially larger space of which the input array, `in`, dimensions given by `n`, is a sub array.

Constraint: Either `inembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `inembed == NULL`, then `inembed` is assumed to have the same dimensions as `n`

`istride` Input parameter

`istride` is `int`

`istride` is the distance between successive elements of the input data

`idist` Input parameter

`idist` is `int`

`idist` is the distance between the start of each of the `howmany` transforms in the input data

`out` Input parameter

`out` is `fftwf_complex*`

`out` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients The output data for set `k` starts at address `out+k*odist`.

Storage: Data in arrays will be stored in row-major order.

`onembed` Input parameter

`onembed` is `const int`

`onembed` is an array of dimension `[rank]` or `NULL`. This array denotes the dimensionality of a potentially larger space of which the input array, `out`, dimensions given by `n`, is a sub array.

Constraint: Either `onembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `onembed == NULL`, then `onembed` is assumed to have the same dimensions as `n`

`ostride` Input parameter

`ostride` is `int`

`ostride` is the distance between successive elements of the output data

`odist` Input parameter

`odist` is `int`

`odist` is the distance between the start of each of the `howmany` transforms in the output data

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.19 fftwh_plan_dft_r2c

`fftwh_plan_dft_r2c` is a basic FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_r2c(int rank, const int *n, __fp16 *in,
                              fftwh_complex *out, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_r2c*`()`.

Parameters

rank Input parameter

rank is int

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

n Input parameter

n is a const int*.

n is an array of dimension [rank].

n contains the size of each dimension of the FFT to be solved

Constraint: n[i] >=1 for i in 1, rank

in Input parameter

in is __fp16

in is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwh_complex*

out is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.20 fftwh_plan_dft_r2c_1d

`fftwh_plan_dft_r2c_1d` is a basic FFTW interface call for planning a 1-d real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_r2c_1d(int n0, __fp16 *in, fftwh_complex *out,
                                 unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_r2c* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the FFT sequence

Constraint: `n0` >= 1

`in` Input parameter

`in` is `__fp16`

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwh_complex*`

`out` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.21 fftwh_plan_dft_r2c_2d

`fftwh_plan_dft_r2c_2d` is a basic FFTW interface call for planning a 2-d real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_r2c_2d(int n0, int n1, __fp16 *in,
                                 fftwh_complex *out, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_r2c* `()`.

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

n1 Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

in Input parameter

`in` is `__fp16`

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is fftwh_complex

`out` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.22 fftwh_plan_dft_r2c_3d

`fftwh_plan_dft_r2c_3d` is a basic FFTW interface call for planning a 3-d real-to-complex FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_r2c_3d(int n0, int n1, int n2, __fp16 *in,
                                 fftwh_complex *out, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_r2c* `()`.

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

n1 Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

n2 Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

in Input parameter

`in` is __fp16

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `fftwh_complex*`

`out` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.23 fftwh_plan_guru_dft_r2c

`fftwh_plan_guru_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_dft_r2c(int rank, const fftwh_iodim *dims,
                                   int howmany_rank,
```

(continues on next page)

(continued from previous page)

```
                                const fftwh_iodim *howmany_dims,
                                __fp16 *in, fftwh_complex *out,
                                unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwh_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftwh_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `__fp16`

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwh_complex*`

`out` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.24 fftwh_plan_guru_split_dft_r2c

`fftwh_plan_guru_split_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_split_dft_r2c(int rank, const fftwh_iodim *dims,
                                         int howmany_rank,
                                         const fftwh_iodim *howmany_dims,
                                         __fp16 *in, __fp16 *ro,
                                         __fp16 *io, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwh_iodim *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- int n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- int is – the number of memory elements, of type fftwh_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- int os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is __fp16 *

in is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ro Input parameter

ro is __fp16 *

ro is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

io Input parameter

io is __fp16 *

io is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.

- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.25 fftwh_plan_guru64_dft_r2c

`fftwh_plan_guru64_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftwh_plan_guru_dft_r2c*, `fftwh_plan_guru64_dft_r2c` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru64_dft_r2c(int rank, const fftwh_iodim64 *dims,
                                     int howmany_rank,
                                     const fftwh_iodim64 *howmany_dims,
                                     __fp16 *in, fftwh_complex *out,
                                     unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_r2c*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

dims Input parameter

dims is const fftwh_iodim64 *

dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the length of the i th dimension.
- ptrdiff_t is – the stride between successive elements in the input vector in the i th dimension.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: dims.n[i] >= 1 for i in 0, rank-1

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwh_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftwh_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is __fp16

in is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwh_complex*

out is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.26 fftwh_plan_guru64_split_dft_r2c

`fftwh_plan_guru64_split_dft_r2c` is a guru FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Unlike *fftwh_plan_guru_split_dft_r2c*, `fftwh_plan_guru64_split_dft_r2c` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_split_dft_r2c(int rank, const fftwh_iodim64 *dims,
                                         int howmany_rank,
```

(continues on next page)

(continued from previous page)

```
                                        const fftwh_iodim64 *howmany_dims,
                                        __fp16 *in, __fp16 *ro,
                                        __fp16 *io, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwh_iodim64 *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t is` – the number of memory elements, of type `fftwh_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `__fp16 *`

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`ro` Input parameter

`ro` is `__fp16 *`

`ro` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the real parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`io` Input parameter

`io` is `__fp16 *`

`io` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the imaginary parts of the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.4.27 fftwh_plan_many_dft_r2c

`fftwh_plan_many_dft_r2c` is an advanced FFTW interface call for planning an *n*-dimensional real-to-complex FFT operation on `howmany` sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

For more information on the use of advanced planning calls see *How to choose which FFT routine you need*.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_many_dft_r2c(int rank, const int *n, int howmany,
                                   __fp16 *in, const int *inembed,
                                   int istride, int idist, fftwh_complex *out,
                                   const int *onembed, int ostride, int odist,
                                   unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_r2c* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is `const int`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, rank

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

`in` Input parameter

`in` is `__fp16`

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT. The input data for set `k` starts at address `in+k*idist`.

Storage: Data in arrays will be stored in row-major order.

`inembed` Input parameter

`inembed` is `const int`

`inembed` is an array of dimension `[rank]` or `NULL`. This array denotes the dimensionality of a potentially larger space of which the input array, `in`, dimensions given by `n`, is a sub array.

Constraint: Either `inembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `inembed == NULL`, then `inembed` is assumed to have the same dimensions as `n`

`istride` Input parameter

`istride` is `int`

`istride` is the distance between successive elements of the input data

`idist` Input parameter

`idist` is `int`

`idist` is the distance between the start of each of the `howmany` transforms in the input data

`out` Input parameter

`out` is `fftwh_complex*`

`out` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients The output data for set `k` starts at address `out+k*odist`.

Storage: Data in arrays will be stored in row-major order.

`onembed` Input parameter

`onembed` is `const int`

`onembed` is an array of dimension `[rank]` or `NULL`. This array denotes the dimensionality of a potentially larger space of which the input array, `out`, dimensions given by `n`, is a sub array.

Constraint: Either `onembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `onembed == NULL`, then `onembed` is assumed to have the same dimensions as `n`

`ostride` Input parameter

`ostride` is `int`

`ostride` is the distance between successive elements of the output data

`odist` Input parameter

`odist` is `int`

`odist` is the distance between the start of each of the `howmany` transforms in the output data

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.

- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.5 FFT complex to real functions

5.5.1 fftw_plan_dft_c2r

fftw_plan_dft_c2r is a basic FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_c2r(int rank, const int *n, fftw_complex *in,
                            double *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_c2r(rank,n,in,out,flags) &
    bind(C, name='fftw_plan_dft_c2r')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_dft_c2r
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_c2r* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, `rank`

`in` Input parameter

in is fftw_complex

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.

- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.5.2 fftw_plan_dft_c2r_1d

fftw_plan_dft_c2r_1d is a basic FFTW interface call for planning a 1-d complex-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_c2r_1d(int n0, fftw_complex *in, double *out,
                               unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_c2r_1d(n,in,out,flags) &
    bind(C, name='fftw_plan_dft_c2r_1d')
  integer(C_INT), value :: n
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_dft_c2r_1d
```

Returns

An fftw_plan object is returned that can be used in subsequent *fftw_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftw_execute_dft_c2r*().

Parameters

n0 Input parameter

n0 is int

This is the length of the FFT sequence

Constraint: `n0` >= 1

`in` Input parameter

`in` is `fftw_complex*`

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.3 fftw_plan_dft_c2r_2d

`fftw_plan_dft_c2r_2d` is a basic FFTW interface call for planning a 2-d complex-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_c2r_2d(int n0, int n1, fftw_complex *in,
                               double *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_c2r_2d(n0,n1,in,out,flags) &
    bind(C, name='fftw_plan_dft_c2r_2d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_dft_c2r_2d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_c2r* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`in` Input parameter

`in` is `fftw_complex*`

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

out is double

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.4 fftw_plan_dft_c2r_3d

`fftw_plan_dft_c2r_3d` is a basic FFTW interface call for planning a 3-d complex-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_dft_c2r_3d(int n0, int n1, int n2, fftw_complex *in,
                               double *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_dft_c2r_3d(n0,n1,n2,in,out,flags) &
    bind(C, name='fftw_plan_dft_c2r_3d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  integer(C_INT), value :: n2
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_dft_c2r_3d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_c2r* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`n2` Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

`in` Input parameter

`in` is fftw_complex

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.5 fftw_plan_guru_dft_c2r

`fftw_plan_guru_dft_c2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_dft_c2r(int rank, const fftw_iodim *dims,
                                 int howmany_rank,
                                 const fftw_iodim *howmany_dims,
                                 fftw_complex *in, double *out,
                                 unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru_dft_c2r(rank,dims,howmany_rank, &
    howmany_dims,in,out,flags) &
    bind(C, name='fftw_plan_guru_dft_c2r')
  integer(C_INT), value :: rank
  type(fftw_iodim), dimension(*), intent(in) :: dims
```

(continues on next page)

(continued from previous page)

```
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim), dimension(*), intent(in) :: howmany_dims
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_guru_dft_c2r
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftw_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftw_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.

- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `fftw_complex*`

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftw_complex*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.6 fftw_plan_guru_split_dft_c2r

`fftw_plan_guru_split_dft_c2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_split_dft_c2r(int rank, const fftw_iodim *dims,
                                       int howmany_rank,
                                       const fftw_iodim *howmany_dims,
                                       double *ri, double *ii, double *out,
                                       unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru_split_dft_c2r(rank,dims, &
    howmany_rank,howmany_dims,ri,ii,out,flags) &
    bind(C, name='fftw_plan_guru_split_dft_c2r')
  integer(C_INT), value :: rank
  type(fftw_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_DOUBLE), dimension(*), intent(out) :: ri
  real(C_DOUBLE), dimension(*), intent(out) :: ii
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_guru_split_dft_c2r
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.

- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

howmany_rank Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

`howmany_dims` is `const fftw_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftw_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

ri Input parameter

`ri` is `double *`

`ri` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ii Input parameter

`ii` is `double *`

`ii` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `double *`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.7 fftw_plan_guru64_dft_c2r

`fftw_plan_guru64_dft_c2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftw_plan_guru_dft_c2r*, `fftw_plan_guru64_dft_c2r` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru64_dft_c2r(int rank, const fftw_iodim64 *dims,
                                   int howmany_rank,
                                   const fftw_iodim64 *howmany_dims,
                                   fftw_complex *in, double *out,
                                   unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru64_dft_c2r(rank,dims,howmany_rank, &
    howmany_dims,in,out,flags) &
    bind(C, name='fftw_plan_guru64_dft_c2r')
  integer(C_INT), value :: rank
  type(fftw_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim64), dimension(*), intent(in) :: howmany_dims
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_guru64_dft_c2r
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftw_iodim64 *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t is` – the number of memory elements, of type `fftw_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `fftw_complex*`

`in` is a pointer to a previously allocated array of `fftw_complex` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.8 fftw_plan_guru64_split_dft_c2r

`fftw_plan_guru64_split_dft_c2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Unlike *fftw_plan_guru_split_dft_c2r*, `fftw_plan_guru64_split_dft_c2r` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_split_dft_c2r(int rank, const fftw_iodim64 *dims,
                                       int howmany_rank,
                                       const fftw_iodim64 *howmany_dims,
                                       double *ri, double *ii, double *out,
                                       unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru64_split_dft_c2r(rank,dims, &
    howmany_rank,howmany_dims,ri,ii,out,flags) &
    bind(C, name='fftw_plan_guru64_split_dft_c2r')
  integer(C_INT), value :: rank
  type(fftw_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim64), dimension(*), intent(in) :: howmany_dims
  real(C_DOUBLE), dimension(*), intent(out) :: ri
  real(C_DOUBLE), dimension(*), intent(out) :: ii
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftw_plan_guru64_split_dft_c2r
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftw_iodim64 *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t is` – the number of memory elements, of type `fftw_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`ri` Input parameter

`ri` is `double *`

`ri` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`ii` Input parameter

`ii` is `double *`

`ii` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `double *`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.9 fftw_plan_many_dft_c2r

`fftw_plan_many_dft_c2r` is an advanced FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on `howmany` sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

For more information on the use of advanced planning calls see *How to choose which FFT routine you need*.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_many_dft_c2r(int rank, const int *n, int howmany,
                                 fftw_complex *in, const int *inembed,
                                 int istride, int idist, double *out,
                                 const int *onembed, int ostride,
                                 int odist, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_many_dft_c2r(rank,n,howmany,in,inembed, &
    istride,idist,out,onembed,ostride,odist,flags) &
    bind(C, name='fftw_plan_many_dft_c2r')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  integer(C_INT), value :: howmany
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  integer(C_INT), dimension(*), intent(in) :: inembed
  integer(C_INT), value :: istride
  integer(C_INT), value :: idist
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), dimension(*), intent(in) :: onembed
  integer(C_INT), value :: ostride
  integer(C_INT), value :: odist
  integer(C_INT), value :: flags
end function fftw_plan_many_dft_c2r
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft_c2r* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is `const int`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, rank

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

in Input parameter

in is fftw_complex*

in is a pointer to a previously allocated array of fftw_complex data. At fftw_execute() time this will have been filled with the input sequence on which to perform the FFT. The input data for set k starts at address in+k*idist.

Storage: Data in arrays will be stored in row-major order.

inembed Input parameter

inembed is const int

inembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, in, dimensions given by n, is a sub array.

Constraint: Either inembed[i] >= n[i] for i in 0, rank-1 OR if inembed == NULL, then inembed is assumed to have the same dimensions as n

istride Input parameter

istride is int

istride is the distance between successive elements of the input data

idist Input parameter

idist is int

idist is the distance between the start of each of the howmany transforms in the input data

out Input parameter

out is double*

out is a pointer to a previously allocated array of double data. At fftw_execute() time this will be filled with the resulting transform coefficients The output data for set k starts at address out+k*odist.

Storage: Data in arrays will be stored in row-major order.

onembed Input parameter

onembed is const int

onembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, out, dimensions given by n, is a sub array.

Constraint: Either onembed[i] >= n[i] for i in 0, rank-1 OR if onembed == NULL, then onembed is assumed to have the same dimensions as n

ostride Input parameter

ostride is int

ostride is the distance between successive elements of the output data

odist Input parameter

odist is int

odist is the distance between the start of each of the howmany transforms in the output data

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.

- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.5.10 fftwf_plan_dft_c2r

fftwf_plan_dft_c2r is a basic FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_c2r(int rank, const int *n, fftwf_complex *in,
                              float *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_c2r(rank,n,in,out,flags) &
    bind(C, name='fftwf_plan_dft_c2r')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_dft_c2r
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_c2r* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, `rank`

`in` Input parameter

in is fftwf_complex

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.

- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.5.11 fftwf_plan_dft_c2r_1d

fftwf_plan_dft_c2r_1d is a basic FFTW interface call for planning a 1-d complex-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_c2r_1d(int n0, fftwf_complex *in, float *out,
                                 unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_c2r_1d(n,in,out,flags) &
    bind(C, name='fftwf_plan_dft_c2r_1d')
  integer(C_INT), value :: n
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_dft_c2r_1d
```

Returns

This function returns an fftwf_plan object that can be used in subsequent *fftwf_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftwf_execute_dft_c2r*().

Parameters

n0 Input parameter

n0 is int

This is the length of the FFT sequence

Constraint: `n0` >= 1

`in` Input parameter

`in` is `fftwf_complex*`

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.12 fftwf_plan_dft_c2r_2d

`fftwf_plan_dft_c2r_2d` is a basic FFTW interface call for planning a 2-d complex-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_c2r_2d(int n0, int n1, fftwf_complex *in,
                                 float *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_c2r_2d(n0,n1,in,out,flags) &
    bind(C, name='fftwf_plan_dft_c2r_2d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_dft_c2r_2d
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_c2r*`()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`in` Input parameter

`in` is `fftwf_complex*`

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

out is float

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.13 fftwf_plan_dft_c2r_3d

`fftwf_plan_dft_c2r_3d` is a basic FFTW interface call for planning a 3-d complex-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_dft_c2r_3d(int n0, int n1, int n2, fftwf_complex *in,
                                 float *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_dft_c2r_3d(n0,n1,n2,in,out,flags) &
    bind(C, name='fftwf_plan_dft_c2r_3d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  integer(C_INT), value :: n2
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_dft_c2r_3d
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_c2r* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`n2` Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

`in` Input parameter

`in` is fftwf_complex

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.14 fftwf_plan_guru_dft_c2r

`fftwf_plan_guru_dft_c2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_dft_c2r(int rank, const fftwf_iodim *dims,
                                   int howmany_rank,
                                   const fftwf_iodim *howmany_dims,
                                   fftwf_complex *in, float *out,
                                   unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru_dft_c2r(rank,dims,howmany_rank, &
    howmany_dims,in,out,flags) &
    bind(C, name='fftwf_plan_guru_dft_c2r')
  integer(C_INT), value :: rank
  type(fftwf_iodim), dimension(*), intent(in) :: dims
```

(continues on next page)

(continued from previous page)

```
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim), dimension(*), intent(in) :: howmany_dims
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_guru_dft_c2r
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwf_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftwf_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.

- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `fftwf_complex*`

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `fftwf_complex*`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.15 fftwf_plan_guru_split_dft_c2r

`fftwf_plan_guru_split_dft_c2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_split_dft_c2r(int rank, const fftwf_iodim *dims,
                                         int howmany_rank,
                                         const fftwf_iodim *howmany_dims,
                                         float *ri, float *ii, float *out,
                                         unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru_split_dft_c2r(rank,dims, &
    howmany_rank,howmany_dims,ri,ii,out,flags) &
    bind(C, name='fftwf_plan_guru_split_dft_c2r')
  integer(C_INT), value :: rank
  type(fftwf_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_FLOAT), dimension(*), intent(out) :: ri
  real(C_FLOAT), dimension(*), intent(out) :: ii
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_guru_split_dft_c2r
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.

- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

howmany_rank Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

howmany_dims Input parameter

`howmany_dims` is `const fftwf_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftwf_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

ri Input parameter

`ri` is `float *`

`ri` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ii Input parameter

`ii` is `float *`

`ii` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `float *`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.16 fftwf_plan_guru64_dft_c2r

`fftwf_plan_guru64_dft_c2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftwf_plan_guru_dft_c2r*, `fftwf_plan_guru64_dft_c2r` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru64_dft_c2r(int rank, const fftwf_iodim64 *dims,
                                     int howmany_rank,
                                     const fftwf_iodim64 *howmany_dims,
                                     fftwf_complex *in, float *out,
                                     unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru64_dft_c2r(rank,dims,howmany_rank, &
    howmany_dims,in,out,flags) &
    bind(C, name='fftwf_plan_guru64_dft_c2r')
  integer(C_INT), value :: rank
  type(fftwf_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim64), dimension(*), intent(in) :: howmany_dims
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_guru64_dft_c2r
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwf_iodim64 *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t is` – the number of memory elements, of type `fftwf_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `fftwf_complex*`

`in` is a pointer to a previously allocated array of `fftwf_complex` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.17 fftwf_plan_guru64_split_dft_c2r

`fftwf_plan_guru64_split_dft_c2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Unlike *fftwf_plan_guru_split_dft_c2r*, `fftwf_plan_guru64_split_dft_c2r` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_split_dft_c2r(int rank, const fftwf_iodim64 *dims,
                                         int howmany_rank,
                                         const fftwf_iodim64 *howmany_dims,
                                         float *ri, float *ii, float *out,
                                         unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru64_split_dft_c2r(rank,dims, &
    howmany_rank,howmany_dims,ri,ii,out,flags) &
    bind(C, name='fftwf_plan_guru64_split_dft_c2r')
  integer(C_INT), value :: rank
  type(fftwf_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim64), dimension(*), intent(in) :: howmany_dims
  real(C_FLOAT), dimension(*), intent(out) :: ri
  real(C_FLOAT), dimension(*), intent(out) :: ii
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), value :: flags
end function fftwf_plan_guru64_split_dft_c2r
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwf_iodim64 *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t is` – the number of memory elements, of type `fftwf_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`ri` Input parameter

`ri` is `float *`

`ri` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`ii` Input parameter

`ii` is `float *`

`ii` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `float *`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.18 fftwf_plan_many_dft_c2r

`fftwf_plan_many_dft_c2r` is an advanced FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on `howmany` sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

For more information on the use of advanced planning calls see *How to choose which FFT routine you need*.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_many_dft_c2r(int rank, const int *n, int howmany,
                                   fftwf_complex *in, const int *inembed,
                                   int istride, int idist, float *out,
                                   const int *onembed, int ostride,
                                   int odist, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_many_dft_c2r(rank,n,howmany,in,inembed, &
    istride,idist,out,onembed,ostride,odist,flags) &
    bind(C, name='fftwf_plan_many_dft_c2r')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  integer(C_INT), value :: howmany
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  integer(C_INT), dimension(*), intent(in) :: inembed
  integer(C_INT), value :: istride
  integer(C_INT), value :: idist
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), dimension(*), intent(in) :: onembed
  integer(C_INT), value :: ostride
  integer(C_INT), value :: odist
  integer(C_INT), value :: flags
end function fftwf_plan_many_dft_c2r
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft_c2r*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is `const int`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, rank

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

in Input parameter

in is fftwf_complex*

in is a pointer to a previously allocated array of fftwf_complex data. At fftwf_execute() time this will have been filled with the input sequence on which to perform the FFT. The input data for set k starts at address in+k*idist.

Storage: Data in arrays will be stored in row-major order.

inembed Input parameter

inembed is const int

inembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, in, dimensions given by n, is a sub array.

Constraint: Either inembed[i] >= n[i] for i in 0, rank-1 OR if inembed == NULL, then inembed is assumed to have the same dimensions as n

istride Input parameter

istride is int

istride is the distance between successive elements of the input data

idist Input parameter

idist is int

idist is the distance between the start of each of the howmany transforms in the input data

out Input parameter

out is float

out is a pointer to a previously allocated array of float data. At fftwf_execute() time this will be filled with the resulting transform coefficients The output data for set k starts at address out+k*odist.

Storage: Data in arrays will be stored in row-major order.

onembed Input parameter

onembed is const int

onembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, out, dimensions given by n, is a sub array.

Constraint: Either onembed[i] >= n[i] for i in 0, rank-1 OR if onembed == NULL, then onembed is assumed to have the same dimensions as n

ostride Input parameter

ostride is int

ostride is the distance between successive elements of the output data

odist Input parameter

odist is int

odist is the distance between the start of each of the howmany transforms in the output data

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.

- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.5.19 fftwh_plan_dft_c2r

fftwh_plan_dft_c2r is a basic FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_c2r(int rank, const int *n, fftwh_complex *in,
                              __fp16 *out, unsigned flags);
```

Returns

This function returns an fftwh_plan object that can be used in subsequent *fftwh_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftwh_execute_dft_c2r*().

Parameters

rank Input parameter

rank is int

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, `rank`

`in` Input parameter

in is fftwh_complex

`in` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `__fp16`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.20 fftwh_plan_dft_c2r_1d

`fftwh_plan_dft_c2r_1d` is a basic FFTW interface call for planning a 1-d complex-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_c2r_1d(int n0, fftwh_complex *in, __fp16 *out,
                                 unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_c2r* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the FFT sequence

Constraint: `n0` >= 1

`in` Input parameter

`in` is `fftwh_complex*`

`in` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `__fp16`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.

- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.21 fftwh_plan_dft_c2r_2d

`fftwh_plan_dft_c2r_2d` is a basic FFTW interface call for planning a 2-d complex-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_c2r_2d(int n0, int n1, fftwh_complex *in,
                                 __fp16 *out, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_c2r*`()`.

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

n1 Input parameter

n1 is int

This is the length of the second dimension of the FFT sequence

Constraint: n1 >= 1

in Input parameter

in is fftwh_complex*

in is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is __fp16

out is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.5.22 fftwh_plan_dft_c2r_3d

`fftwh_plan_dft_c2r_3d` is a basic FFTW interface call for planning a 3-d complex-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_dft_c2r_3d(int n0, int n1, int n2, fftwh_complex *in,
                                 __fp16 *out, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_c2r* `()`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`n2` Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

`in` Input parameter

`in` is fftwh_complex

`in` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `__fp16`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.5.23 fftwh_plan_guru_dft_c2r

fftwh_plan_guru_dft_c2r is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_dft_c2r(int rank, const fftwh_iodim *dims,
                                   int howmany_rank,
                                   const fftwh_iodim *howmany_dims,
                                   fftwh_complex *in, __fp16 *out,
                                   unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwh_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `fftwh_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

in Input parameter

in is fftwh_complex*

in is a pointer to a previously allocated array of fftwh_complex data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is fftwh_complex*

out is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.5.24 fftwh_plan_guru_split_dft_c2r

fftwh_plan_guru_split_dft_c2r is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_split_dft_c2r(int rank, const fftwh_iodim *dims,
                                         int howmany_rank,
                                         const fftwh_iodim *howmany_dims,
                                         __fp16 *ri, __fp16 *ii, __fp16 *out,
                                         unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwh_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.

- `int is` – the number of memory elements, of type `fftwh_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`ri` Input parameter

`ri` is `__fp16 *`

`ri` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`ii` Input parameter

`ii` is `__fp16 *`

`ii` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `__fp16 *`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.

- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.25 fftwh_plan_guru64_dft_c2r

`fftwh_plan_guru64_dft_c2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftwh_plan_guru_dft_c2r*, `fftwh_plan_guru64_dft_c2r` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru64_dft_c2r(int rank, const fftwh_iodim64 *dims,
                                     int howmany_rank,
                                     const fftwh_iodim64 *howmany_dims,
                                     fftwh_complex *in, __fp16 *out,
                                     unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwh_iodim64 *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t is` – the number of memory elements, of type `fftwh_complex`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `fftwh_complex*`

`in` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `__fp16`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.

- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.5.26 fftwh_plan_guru64_split_dft_c2r

`fftwh_plan_guru64_split_dft_c2r` is a guru FFTW interface call for planning an n-dimensional complex-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner. Input and output data is stored in separate arrays for real and imaginary parts.

Unlike *fftwh_plan_guru_split_dft_c2r*, `fftwh_plan_guru64_split_dft_c2r` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_split_dft_c2r(int rank, const fftwh_iodim64 *dims,
                                         int howmany_rank,
                                         const fftwh_iodim64 *howmany_dims,
                                         __fp16 *ri, __fp16 *ii, __fp16 *out,
                                         unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Parameters

rank Input parameter

rank is int

The number of dimensions of each individual FFT problem to be solved.

Constraint: rank >= 1

dims Input parameter

dims is const fftwh_iodim64 *

dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the length of the i th dimension.
- ptrdiff_t is – the stride between successive elements in the input vector in the i th dimension.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: dims.n[i] >= 1 for i in 0, rank-1

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwh_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type fftwh_complex, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

ri Input parameter

ri is __fp16 *

ri is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will have been filled with the real parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

ii Input parameter

ii is __fp16 *

ii is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will have been filled with the imaginary parts of the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is __fp16 *

out is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.5.27 fftwh_plan_many_dft_c2r

fftwh_plan_many_dft_c2r is an advanced FFTW interface call for planning an *n*-dimensional complex-to-real FFT operation on howmany sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

For more information on the use of advanced planning calls see *How to choose which FFT routine you need*.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_many_dft_c2r(int rank, const int *n, int howmany,
                                   fftwh_complex *in, const int *inembed,
                                   int istride, int idist, __fp16 *out,
                                   const int *onembed, int ostride,
                                   int odist, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft_c2r*`()`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is `const int`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, rank

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

`in` Input parameter

`in` is `fftwh_complex*`

`in` is a pointer to a previously allocated array of `fftwh_complex` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT. The input data for set `k` starts at address `in+k*idist`.

Storage: Data in arrays will be stored in row-major order.

`inembed` Input parameter

`inembed` is `const int`

`inembed` is an array of dimension `[rank]` or `NULL`. This array denotes the dimensionality of a potentially larger space of which the input array, `in`, dimensions given by `n`, is a sub array.

Constraint: Either `inembed[i]` >= `n[i]` for `i` in 0, `rank-1` OR if `inembed` == `NULL`, then `inembed` is assumed to have the same dimensions as `n`

istride Input parameter

istride is int

istride is the distance between successive elements of the input data

idist Input parameter

idist is int

idist is the distance between the start of each of the howmany transforms in the input data

out Input parameter

out is __fp16

out is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the resulting transform coefficients The output data for set k starts at address out+k*odist.

Storage: Data in arrays will be stored in row-major order.

onembed Input parameter

onembed is const int

onembed is an array of dimension [rank] or NULL. This array denotes the dimensionality of a potentially larger space of which the input array, out, dimensions given by n, is a sub array.

Constraint: Either onembed[i] >= n[i] for i in 0, rank-1 OR if onembed == NULL, then onembed is assumed to have the same dimensions as n

ostride Input parameter

ostride is int

ostride is the distance between successive elements of the output data

odist Input parameter

odist is int

odist is the distance between the start of each of the howmany transforms in the output data

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.

- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6 FFT real to real functions

5.6.1 fftw_plan_guru_r2r

`fftw_plan_many_r2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru_r2r(int rank, const fftw_iodim *dims,
                             int howmany_rank,
                             const fftw_iodim *howmany_dims,
                             double *in, double *out,
                             unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru_r2r(rank,dims,howmany_rank, &
    howmany_dims,in,out,kind,flags) &
    bind(C, name='fftw_plan_guru_r2r')
  integer(C_INT), value :: rank
  type(fftw_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_DOUBLE), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_FFTW_R2R_KIND), dimension(*), intent(in) :: kind
  integer(C_INT), value :: flags
end function fftw_plan_guru_r2r
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftw_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftw_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `double`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

in Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.2 fftw_plan_guru64_dft_r2r

`fftw_plan_guru64_dft` is a guru FFTW interface call for planning an *n*-dimensional real-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftw_plan_guru_dft*, `fftw_plan_guru64_dft` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_guru64_dft(int rank, const fftw_iodim64 *dims,
                               int howmany_rank,
                               const fftw_iodim64 *howmany_dims,
                               double *in, double *out,
                               unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_guru64_dft(rank,dims,howmany_rank, &
    howmany_dims,in,out,sign,flags) &
    bind(C, name='fftw_plan_guru64_dft')
  integer(C_INT), value :: rank
  type(fftw_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftw_iodim64), dimension(*), intent(in) :: howmany_dims
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftw_plan_guru64_dft
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_dft* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

dims Input parameter

dims is const fftw_iodim64 *

dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the length of the i th dimension.
- ptrdiff_t is – the stride between successive elements in the input vector in the i th dimension.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: dims.n[i] >= 1 for i in 0, rank-1

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftw_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type double, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is double*

in is a pointer to a previously allocated array of double data. At fftw_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is double*

out is a pointer to a previously allocated array of double data. At fftw_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.3 fftw_plan_many_r2r

`fftw_plan_many_r2r` is an advanced FFTW interface call for planning an *n*-dimensional real-to-real FFT operation on `howmany` sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_many_r2r(int rank, const int *n, int howmany,
                             double *in, const int *inembed, int istride,
                             int idist, double *out, const int *onembed,
                             int ostride, int odist, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_many_r2r(rank,n,howmany,in,inembed, &
    istride,idist,out,onembed,ostride,odist,kind,flags) &
    bind(C, name='fftw_plan_many_r2r')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  integer(C_INT), value :: howmany
  real(C_DOUBLE), dimension(*), intent(out) :: in
  integer(C_INT), dimension(*), intent(in) :: inembed
  integer(C_INT), value :: istride
  integer(C_INT), value :: idist
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_INT), dimension(*), intent(in) :: onembed
  integer(C_INT), value :: ostride
  integer(C_INT), value :: odist
  integer(C_FFTW_R2R_KIND), dimension(*), intent(in) :: kind
  integer(C_INT), value :: flags
end function fftw_plan_many_r2r
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank`

Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is `const int`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, rank

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

`in` Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`inembed` Input parameter

`inembed` is `const int`

`inembed` is a pointer to a previously allocated array of `double` data. This array denotes the dimensionality of a potentially larger space of which the input array, `in`, dimensions given by `n`, is a sub array.

Constraint: Either `inembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `inembed == NULL`, then `inembed` is assumed to have the same dimensions as `n`

`istride` Input parameter

`istride` is `int`

`istride` is the distance between successive elements of the input data

`idist` Input parameter

`idist` is `int`

`idist` is the distance between the start of each of the `howmany` transforms in the input data

`out`

Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`onembed` Input parameter

`onembed` is `const int`

`onembed` is an array of dimension `[rank]` or `NULL`. This array denotes the dimensionality of a potentially larger space of which the input array, `out`, dimensions given by `n`, is a sub array.

Constraint: Either `onembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `onembed == NULL`, then `onembed` is assumed to have the same dimensions as `n`

`ostride` Input parameter

`ostride` is `int`

`ostride` is the distance between successive elements of the output data

`odist` Input parameter

`odist` is `int`

`odist` is the distance between the start of each of the `howmany` transforms in the output data

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.

- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.6.4 fftw_plan_r2r

fftw_plan_r2r is a basic FFTW interface call for planning an *n*-dimensional real-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return NULL.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_r2r(int rank, const int *n, double *in, double *out,
                        unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_r2r(rank,n,in,out,kind,flags) &
    bind(C, name='fftw_plan_r2r')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  real(C_DOUBLE), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
```

(continues on next page)

(continued from previous page)

```
  integer(C_FFTW_R2R_KIND), dimension(*), intent(in) :: kind
  integer(C_INT), value :: flags
end function fftw_plan_r2r
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >=1 for i in 1, `rank`

`in` Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.

- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.6.5 fftw_plan_r2r_1d

fftw_plan_r2r_1d is a basic FFTW interface call for planning a 1-d real-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return NULL.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_r2r_1d(int n0, double *in, double *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_r2r_1d(n,in,out,kind,flags) &
    bind(C, name='fftw_plan_r2r_1d')
  integer(C_INT), value :: n
  real(C_DOUBLE), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_FFTW_R2R_KIND), value :: kind
  integer(C_INT), value :: flags
end function fftw_plan_r2r_1d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the FFT sequence

Constraint: `n0` >= 1

`in` Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.

- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.6 fftw_plan_r2r_2d

`fftw_plan_r2r_2d` is a basic FFTW interface call for planning a 2-d real-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_r2r_2d(int n0, int n1, double *in, double *out,
                           unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_r2r_2d(n0,n1,in,out,kind0,kind1,flags) &
    bind(C, name='fftw_plan_r2r_2d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  real(C_DOUBLE), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_FFTW_R2R_KIND), value :: kind0
  integer(C_FFTW_R2R_KIND), value :: kind1
  integer(C_INT), value :: flags
end function fftw_plan_r2r_2d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_r2r*`()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

n1 Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

in Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.7 fftw_plan_r2r_3d

`fftw_plan_r2r_3d` is a basic FFTW interface call for planning a 3-d real-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftw_plan fftw_plan_r2r_3d(int n0, int n1, int n2, double *in, double *out,
                           unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_plan_r2r_3d(n0,n1,n2,in,out,kind0,kind1, &
    kind2,flags) bind(C, name='fftw_plan_r2r_3d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  integer(C_INT), value :: n2
  real(C_DOUBLE), dimension(*), intent(out) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
  integer(C_FFTW_R2R_KIND), value :: kind0
  integer(C_FFTW_R2R_KIND), value :: kind1
  integer(C_FFTW_R2R_KIND), value :: kind2
  integer(C_INT), value :: flags
end function fftw_plan_r2r_3d
```

Returns

An `fftw_plan` object is returned that can be used in subsequent *fftw_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftw_execute_r2r*`()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

n1 Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

n2 Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

in Input parameter

`in` is double

`in` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of `double` data. At `fftw_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.

- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftw_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.8 fftwf_plan_guru_r2r

`fftwf_plan_many_r2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru_r2r(int rank, const fftwf_iodim *dims,
                               int howmany_rank,
                               const fftwf_iodim *howmany_dims,
                               float *in, float *out,
                               unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru_r2r(rank,dims,howmany_rank, &
    howmany_dims,in,out,kind,flags) &
    bind(C, name='fftwf_plan_guru_r2r')
  integer(C_INT), value :: rank
  type(fftwf_iodim), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim), dimension(*), intent(in) :: howmany_dims
  real(C_FLOAT), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_FFTW_R2R_KIND), dimension(*), intent(in) :: kind
  integer(C_INT), value :: flags
end function fftwf_plan_guru_r2r
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwf_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwf_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `float`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

in Input parameter

`in` is `float`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.9 fftwf_plan_guru64_dft

`fftwf_plan_guru64_dft` is a guru FFTW interface call for planning an *n*-dimensional real-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftwf_plan_guru_dft*, `fftwf_plan_guru64_dft` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_guru64_dft(int rank, const fftwf_iodim64 *dims,
                                 int howmany_rank,
                                 const fftwf_iodim64 *howmany_dims,
                                 float *in, float *out,
                                 unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_guru64_dft(rank,dims,howmany_rank, &
    howmany_dims,in,out,sign,flags) &
    bind(C, name='fftwf_plan_guru64_dft')
  integer(C_INT), value :: rank
  type(fftwf_iodim64), dimension(*), intent(in) :: dims
  integer(C_INT), value :: howmany_rank
  type(fftwf_iodim64), dimension(*), intent(in) :: howmany_dims
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
  integer(C_INT), value :: sign
  integer(C_INT), value :: flags
end function fftwf_plan_guru64_dft
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_dft* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

dims Input parameter

dims is const fftwf_iodim64 *

dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the length of the i th dimension.
- ptrdiff_t is – the stride between successive elements in the input vector in the i th dimension.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: dims.n[i] >= 1 for i in 0, rank-1

howmany_rank Input parameter

howmany_rank is int

howmany_rank is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then howmany_rank needs only be 1.

Constraint: howmany >= 0

Note: If howmany_rank=0, then a single FFT transform is computed.

howmany_dims Input parameter

howmany_dims is const fftwf_iodim64 *

howmany_dims is an array of structures, dimension [rank], where the members of dims[i], for i in 0, rank-1, are defined to be:

- ptrdiff_t n – the number of transforms to be computed of the i th dimension.of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t is – the number of memory elements, of type float, between the start of transforms in the i th dimension. of the howmany_rank-dimensional space mapped by the transforms to be computed.
- ptrdiff_t os – the stride between successive elements in the output vector in the i th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is float

in is a pointer to a previously allocated array of float data. At fftwf_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is float

out is a pointer to a previously allocated array of float data. At fftwf_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.10 fftwf_plan_many_r2r

`fftwf_plan_many_r2r` is an advanced FFTW interface call for planning an *n*-dimensional real-to-real FFT operation on `howmany` sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_many_r2r(int rank, const int *n, int howmany,
                               float *in, const int *inembed, int istride,
                               int idist, float *out, const int *onembed,
                               int ostride, int odist, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_many_r2r(rank,n,howmany,in,inembed, &
    istride,idist,out,onembed,ostride,odist,kind,flags) &
    bind(C, name='fftwf_plan_many_r2r')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  integer(C_INT), value :: howmany
  real(C_FLOAT), dimension(*), intent(out) :: in
  integer(C_INT), dimension(*), intent(in) :: inembed
  integer(C_INT), value :: istride
  integer(C_INT), value :: idist
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_INT), dimension(*), intent(in) :: onembed
  integer(C_INT), value :: ostride
  integer(C_INT), value :: odist
  integer(C_FFTW_R2R_KIND), dimension(*), intent(in) :: kind
  integer(C_INT), value :: flags
end function fftwf_plan_many_r2r
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank`

Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

`n` Input parameter

`n` is `const int`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, rank

`howmany` Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

`in` Input parameter

`in` is `float`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`inembed` Input parameter

`inembed` is `const int`

`inembed` is a pointer to a previously allocated array of `float` data. This array denotes the dimensionality of a potentially larger space of which the input array, `in`, dimensions given by `n`, is a sub array.

Constraint: Either `inembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `inembed == NULL`, then `inembed` is assumed to have the same dimensions as `n`

`istride` Input parameter

`istride` is `int`

`istride` is the distance between successive elements of the input data

`idist` Input parameter

`idist` is `int`

`idist` is the distance between the start of each of the `howmany` transforms in the input data

`out`

Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`onembed` Input parameter

`onembed` is `const int`

`onembed` is an array of dimension `[rank]` or `NULL`. This array denotes the dimensionality of a potentially larger space of which the input array, `out`, dimensions given by `n`, is a sub array.

Constraint: Either `onembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `onembed == NULL`, then `onembed` is assumed to have the same dimensions as `n`

`ostride` Input parameter

`ostride` is `int`

`ostride` is the distance between successive elements of the output data

`odist` Input parameter

`odist` is `int`

`odist` is the distance between the start of each of the `howmany` transforms in the output data

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.

- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.6.11 fftwf_plan_r2r

fftwf_plan_r2r is a basic FFTW interface call for planning an *n*-dimensional real-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return NULL.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_r2r(int rank, const int *n, float *in, float *out,
                          unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_r2r(rank,n,in,out,kind,flags) &
    bind(C, name='fftwf_plan_r2r')
  integer(C_INT), value :: rank
  integer(C_INT), dimension(*), intent(in) :: n
  real(C_FLOAT), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
```

(continues on next page)

(continued from previous page)

```
  integer(C_FFTW_R2R_KIND), dimension(*), intent(in) :: kind
  integer(C_INT), value :: flags
end function fftwf_plan_r2r
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >=1 for i in 1, `rank`

`in` Input parameter

`in` is `float`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.

- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.6.12 fftwf_plan_r2r_1d

fftwf_plan_r2r_1d is a basic FFTW interface call for planning a 1-d real-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return NULL.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_r2r_1d(int n0, float *in, float *out, unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_r2r_1d(n,in,out,kind,flags) &
    bind(C, name='fftwf_plan_r2r_1d')
  integer(C_INT), value :: n
  real(C_FLOAT), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_FFTW_R2R_KIND), value :: kind
  integer(C_INT), value :: flags
end function fftwf_plan_r2r_1d
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the FFT sequence

Constraint: `n0` >= 1

`in` Input parameter

`in` is `float`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.

- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.13 fftwf_plan_r2r_2d

`fftwf_plan_r2r_2d` is a basic FFTW interface call for planning a 2-d real-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_r2r_2d(int n0, int n1, float *in, float *out,
                             unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_r2r_2d(n0,n1,in,out,kind0,kind1,flags) &
    bind(C, name='fftwf_plan_r2r_2d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  real(C_FLOAT), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_FFTW_R2R_KIND), value :: kind0
  integer(C_FFTW_R2R_KIND), value :: kind1
  integer(C_INT), value :: flags
end function fftwf_plan_r2r_2d
```

Returns

This function returns an `fftwf_plan` object that can be used in subsequent *fftwf_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwf_execute_r2r*`()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

n1 Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

in Input parameter

`in` is `float`

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.6.14 fftwf_plan_r2r_3d

fftwf_plan_r2r_3d is a basic FFTW interface call for planning a 3-d real-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return NULL.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_plan fftwf_plan_r2r_3d(int n0, int n1, int n2, float *in, float *out,
                             unsigned flags);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_plan_r2r_3d(n0,n1,n2,in,out,kind0,kind1, &
    kind2,flags) bind(C, name='fftwf_plan_r2r_3d')
  integer(C_INT), value :: n0
  integer(C_INT), value :: n1
  integer(C_INT), value :: n2
  real(C_FLOAT), dimension(*), intent(out) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
  integer(C_FFTW_R2R_KIND), value :: kind0
  integer(C_FFTW_R2R_KIND), value :: kind1
  integer(C_FFTW_R2R_KIND), value :: kind2
  integer(C_INT), value :: flags
end function fftwf_plan_r2r_3d
```

Returns

This function returns an fftwf_plan object that can be used in subsequent *fftwf_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftwf_execute_r2r*().

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return NULL.

Parameters

n0 Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

n1 Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

n2 Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

in Input parameter

`in` is float

`in` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `float`

`out` is a pointer to a previously allocated array of `float` data. At `fftwf_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.

- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwf_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.15 fftwh_plan_guru_r2r

`fftwh_plan_many_r2r` is a guru FFTW interface call for planning an *n*-dimensional complex-to-complex FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru_r2r(int rank, const fftwh_iodim *dims,
                               int howmany_rank,
                               const fftwh_iodim *howmany_dims,
                               __fp16 *in, __fp16 *out,
                               unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute*`()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_r2r*`()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the length of the `i` th dimension.
- `int is` – the stride between successive elements in the input vector in the `i` th dimension.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwh_iodim *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `int n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int is` – the number of memory elements, of type `__fp16`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `int os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed is given by the product of the `howmany_dims.n[]` entries. For example, if `howmany_rank=1`, then `howmany_dims[0].n` is the memory distance between successive transforms.

Constraint: `howmany_dims.n[i]` >= 1 for i in 0, `howmany_rank-1`

`in` Input parameter

`in` is `__fp16`

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `__fp16`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.16 fftwh_plan_guru64_dft

`fftwh_plan_guru64_dft` is a guru FFTW interface call for planning an *n*-dimensional real-to-real FFT operation on multiple sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Unlike *fftwh_plan_guru_dft*, `fftwh_plan_guru64_dft` allows selected parameters to be specified as 64-bit integers. For Arm Performance Libraries, this parameter size difference is true in both `armpl*_lp64` and `armpl_ilp64` variants. Therefore, the parameter size difference is independent of the integer size used in the rest of the library interface.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_guru64_dft(int rank, const fftwh_iodim64 *dims,
                                 int howmany_rank,
                                 const fftwh_iodim64 *howmany_dims,
                                 __fp16 *in, __fp16 *out,
                                 unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_dft* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of each individual FFT problem to be solved.

Constraint: `rank` >= 1

`dims` Input parameter

`dims` is `const fftwh_iodim64 *`

`dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the length of the `i` th dimension.
- `ptrdiff_t is` – the stride between successive elements in the input vector in the `i` th dimension.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns of the individual, multi-dimensional FFTs to be performed.

Constraint: `dims.n[i]` >= 1 for i in 0, `rank-1`

`howmany_rank` Input parameter

`howmany_rank` is `int`

`howmany_rank` is the number of dimensions needed to describe the memory access pattern for the start addresses of each of the multi-dimensional FFT transforms to be computed. For example, if all the transforms to be performed are regularly offset in memory, then `howmany_rank` needs only be 1.

Constraint: `howmany` >= 0

Note: If `howmany_rank=0`, then a single FFT transform is computed.

`howmany_dims` Input parameter

`howmany_dims` is `const fftwh_iodim64 *`

`howmany_dims` is an array of structures, dimension `[rank]`, where the members of `dims[i]`, for `i` in 0, `rank-1`, are defined to be:

- `ptrdiff_t n` – the number of transforms to be computed of the `i` th dimension.of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t is` – the number of memory elements, of type `__fp16`, between the start of transforms in the `i` th dimension. of the `howmany_rank`-dimensional space mapped by the transforms to be computed.
- `ptrdiff_t os` – the stride between successive elements in the output vector in the `i` th dimension.

This parameters collectively define the size of each dimension and memory access patterns from the multi-dimensional array of transforms that need to be performed. The total number of transforms to be computed

is given by the product of the howmany_dims.n[] entries. For example, if howmany_rank=1, then howmany_dims[0].n is the memory distance between successive transforms.

Constraint: howmany_dims.n[i] >= 1 for i in 0, howmany_rank-1

in Input parameter

in is __fp16

in is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is __fp16

out is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation.

Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.6.17 fftwh_plan_many_r2r

`fftwh_plan_many_r2r` is an advanced FFTW interface call for planning an *n*-dimensional real-to-real FFT operation on `howmany` sets of data. The data for an individual FFT does not need to be contiguous, and can be provided in a strided manner.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_many_r2r(int rank, const int *n, int howmany,
                               __fp16 *in, const int *inembed, int istride,
                               int idist, __fp16 *out, const int *onembed,
                               int ostride, int odist, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

rank

Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: rank >= 1

n Input parameter

`n` is `const int`

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >= 1 for i in 1, rank

howmany Input parameter

`howmany` is `int`

`howmany` is the number of multi-dimensional FFT transforms to be computed

Constraint: `howmany` >= 1

in Input parameter

`in` is `__fp16`

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

inembed Input parameter

`inembed` is `const int`

`inembed` is a pointer to a previously allocated array of `__fp16` data. This array denotes the dimensionality of a potentially larger space of which the input array, `in`, dimensions given by `n`, is a sub array.

Constraint: Either `inembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `inembed == NULL`, then `inembed` is assumed to have the same dimensions as `n`

istride Input parameter

`istride` is `int`

`istride` is the distance between successive elements of the input data

idist Input parameter

`idist` is `int`

`idist` is the distance between the start of each of the `howmany` transforms in the input data

out

Input parameter

`out` is `__fp16`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

onembed Input parameter

`onembed` is `const int`

`onembed` is an array of dimension `[rank]` or `NULL`. This array denotes the dimensionality of a potentially larger space of which the input array, `out`, dimensions given by `n`, is a sub array.

Constraint: Either `onembed[i] >= n[i]` for `i` in 0, `rank-1` OR if `onembed == NULL`, then `onembed` is assumed to have the same dimensions as `n`

ostride Input parameter

`ostride` is `int`

`ostride` is the distance between successive elements of the output data

odist Input parameter

`odist` is `int`

`odist` is the distance between the start of each of the `howmany` transforms in the output data

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.

- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.18 fftwh_plan_r2r

`fftwh_plan_r2r` is a basic FFTW interface call for planning an *n*-dimensional real-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_r2r(int rank, const int *n, __fp16 *in, __fp16 *out,
                          unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`rank` Input parameter

`rank` is `int`

The number of dimensions of the FFT problem to be solved

Constraint: `rank` >= 1

`n` Input parameter

`n` is `const int*`.

`n` is an array of dimension `[rank]`.

`n` contains the size of each dimension of the FFT to be solved

Constraint: `n[i]` >=1 for i in 1, `rank`

`in` Input parameter

`in` is `__fp16`

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `__fp16`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.

- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.19 fftwh_plan_r2r_1d

`fftwh_plan_r2r_1d` is a basic FFTW interface call for planning a 1-d real-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_r2r_1d(int n0, __fp16 *in, __fp16 *out, unsigned flags);
```

Returns

This function returns an `fftwh_plan` object that can be used in subsequent *fftwh_execute* `()` calls on the previously supplied `in` and `out` arrays, or using different arrays via *fftwh_execute_r2r* `()`.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the FFT sequence

Constraint: `n0` >= 1

in Input parameter

`in` is `__fp16`

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

`out` is `__fp16`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.
- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.6.20 fftwh_plan_r2r_2d

`fftwh_plan_r2r_2d` is a basic FFTW interface call for planning a 2-d real-to-real FFT operation on a single, contiguous data sequence.

Note: `in` and `out` can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return NULL.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_r2r_2d(int n0, int n1, __fp16 *in, __fp16 *out,
                             unsigned flags);
```

Returns

This function returns an fftwh_plan object that can be used in subsequent *fftwh_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftwh_execute_r2r*().

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return NULL.

Parameters

n0 Input parameter

n0 is int

This is the length of the first dimension of the FFT sequence

Constraint: n0 >= 1

n1 Input parameter

n1 is int

This is the length of the second dimension of the FFT sequence

Constraint: n1 >= 1

in Input parameter

in is __fp16

in is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

out Input parameter

out is __fp16

out is a pointer to a previously allocated array of __fp16 data. At fftwh_execute() time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

flags Input parameter

flags is unsigned

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in flags are:

- FFTW_ESTIMATE – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- FFTW_MEASURE – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- FFTW_PATIENT – Produce a plan, testing more options than FFTW_MEASURE. Input and output data might be overwritten.
- FFTW_EXHAUSTIVE – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- FFTW_WISDOM_ONLY – Produce a plan only if the requested case has existing wisdom, otherwise return NULL.
- FFTW_PRESERVE_INPUT – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- FFTW_DESTROY_INPUT – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- FFTW_CONSERVE_MEMORY – Request that extra memory is not created. This might be ignored.
- FFTW_UNALIGNED – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by FFTW_MEASURE, FFTW_PATIENT and FFTW_EXHAUSTIVE will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in flags, then the highest level of planning requested will be used.

5.6.21 fftwh_plan_r2r_3d

fftwh_plan_r2r_3d is a basic FFTW interface call for planning a 3-d real-to-real FFT operation on a single, contiguous data sequence.

Note: in and out can be the same pointer for an "in-place" transform.

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return NULL.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_plan fftwh_plan_r2r_3d(int n0, int n1, int n2, __fp16 *in, __fp16 *out,
                             unsigned flags);
```

Returns

This function returns an fftwh_plan object that can be used in subsequent *fftwh_execute*() calls on the previously supplied in and out arrays, or using different arrays via *fftwh_execute_r2r*().

Note: Real-to-real transforms are not available in Arm Performance Libraries at present and will always return `NULL`.

Parameters

`n0` Input parameter

`n0` is `int`

This is the length of the first dimension of the FFT sequence

Constraint: `n0` >= 1

`n1` Input parameter

`n1` is `int`

This is the length of the second dimension of the FFT sequence

Constraint: `n1` >= 1

`n2` Input parameter

`n2` is `int`

This is the length of the third dimension of the FFT sequence

Constraint: `n2` >= 1

`in` Input parameter

`in` is __fp16

`in` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will have been filled with the input sequence on which to perform the FFT.

Storage: Data in arrays will be stored in row-major order.

`out` Input parameter

`out` is `__fp16`

`out` is a pointer to a previously allocated array of `__fp16` data. At `fftwh_execute()` time this will be filled with the resulting transform coefficients

Storage: Data in arrays will be stored in row-major order.

`flags` Input parameter

`flags` is `unsigned`

This variable combines various options that the user can supply to aid the planning. These can be combined using a bitwise OR operation. Valid options for inclusion in `flags` are:

- `FFTW_ESTIMATE` – Produce a plan quickly, without testing how good the chosen option is. Input and output data is guaranteed to be preserved.
- `FFTW_MEASURE` – Produce a plan, having tested a small number of options to find the fastest choice. Input and output data might be overwritten.
- `FFTW_PATIENT` – Produce a plan, testing more options than `FFTW_MEASURE`. Input and output data might be overwritten.
- `FFTW_EXHAUSTIVE` – Produce a plan, having tested as wide a variety of cases as possible, in order to find the best performing method.
- `FFTW_WISDOM_ONLY` – Produce a plan only if the requested case has existing wisdom, otherwise return `NULL`.

- `FFTW_PRESERVE_INPUT` – On execution of an out-of-place transform, insist that input data is not overwritten. For Arm Performance Libraries this the default in all cases.
- `FFTW_DESTROY_INPUT` – Allow planning to overwrite input data in executing out-of-place transforms. This is not needed in Arm Performance Libraries because input data is not overwritten for these transforms.
- `FFTW_CONSERVE_MEMORY` – Request that extra memory is not created. This might be ignored.
- `FFTW_UNALIGNED` – Indicate that arrays might be aligned differently at execution time than at planning, and that plans should account for this.

Notes:

- The planning times indicated by `FFTW_MEASURE`, `FFTW_PATIENT` and `FFTW_EXHAUSTIVE` will be limited when using *fftwh_set_timelimit*.
- If multiple options for planning rigor are included in `flags`, then the highest level of planning requested will be used.

5.7 FFT executors functions

5.7.1 fftw_execute

`fftw_execute` executes a previously created FFT plan.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_execute(const fftw_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

 subroutine fftw_execute_dft(p,in,out) bind(C, name='fftw_execute_dft')
   type(C_PTR), value :: p
   complex(C_DOUBLE_COMPLEX), dimension(*), intent(inout) :: in
   complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
 end subroutine fftw_execute_dft
```

Parameters

p Input parameter

`p` is `fftw_plan`

An FFT plan created from a preceding call

5.7.2 fftw_execute_dft

`fftw_execute_dft` executes a previously created FFT plan, however input and output data locations maybe different than those given at planning time.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_execute_dft(const fftw_plan p, fftw_complex *in,
                      fftw_complex *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_execute_dft(p,in,out) bind(C, name='fftw_execute_dft')
  type(C_PTR), value :: p
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(inout) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
end subroutine fftw_execute_dft
```

Parameters

p Input parameter

p is fftw_plan

An FFT plan created from a preceding call

in Input parameter

in is fftw_complex*

in is a pointer to a previously allocated array of data, on which to calculate a complex-to-complex FFT

out Output parameter

out is fftw_complex*

out is a pointer to a previously allocated array of data, into which to return the results of the complex-to-complex FFT

5.7.3 fftw_execute_dft_c2r

fftw_execute_dft_c2r executes a previously created complex-to-real FFT plan, however input and output data locations maybe different than those given at planning time.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_execute_dft_c2r(const fftw_plan p, fftw_complex *in,
                          double *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_execute_dft_c2r(p,in,out) &
```

(continues on next page)

(continued from previous page)

```
    bind(C, name='fftw_execute_dft_c2r')
  type(C_PTR), value :: p
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(inout) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
end subroutine fftw_execute_dft_c2r
```

Parameters

p Input parameter

p is fftw_plan

An FFT plan created from a preceding call

in Input parameter

in is fftw_complex*

in is a pointer to a previously allocated array of data, on which to calculate a complex-to-real FFT

out output out is double*

out is a pointer to a previously allocated array of data, into which to return the results of the complex-to-real FFT

5.7.4 fftw_execute_dft_r2c

fftw_execute_dft_r2c executes a previously created FFT plan, however input and output data locations maybe different than those given at planning time.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_execute_dft_r2c(const fftw_plan p, double *in,
                          fftw_complex *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_execute_dft_r2c(p,in,out) &
    bind(C, name='fftw_execute_dft_r2c')
  type(C_PTR), value :: p
  real(C_DOUBLE), dimension(*), intent(inout) :: in
  complex(C_DOUBLE_COMPLEX), dimension(*), intent(out) :: out
end subroutine fftw_execute_dft_r2c
```

Parameters

p Input parameter

p is fftw_plan

An FFT plan created from a preceding call

in Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of data, on which to calculate a real-to-complex FFT

out Output parameter

`out` is `fftw_complex*`

`out` is a pointer to a previously allocated array of data, into which to return the results of the real-to-complex FFT

5.7.5 fftw_execute_r2r

`fftw_execute_r2r` executes a previously created real-to-real FFT plan, however input and output data locations maybe different than those given at planning time.

Note: Since real-to-real transforms are not currently available in Arm Performance Libraries it is impossible to provide a valid plan, `p`, to pass to this function.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_execute_r2r(const fftw_plan p, double *in, double *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_execute_r2r(p,in,out) bind(C, name='fftw_execute_r2r')
  type(C_PTR), value :: p
  real(C_DOUBLE), dimension(*), intent(inout) :: in
  real(C_DOUBLE), dimension(*), intent(out) :: out
end subroutine fftw_execute_r2r
```

Parameters

p Input parameter

`p` is `fftw_plan`

An FFT plan created from a preceding call

in Input parameter

`in` is `double*`

`in` is a pointer to a previously allocated array of data, on which to calculate a real-to-real FFT

out Output parameter

`out` is `double*`

`out` is a pointer to a previously allocated array of data, into which to return the results of the real-to-real FFT

5.7.6 fftwf_execute

`fftwf_execute` executes a previously created FFT plan.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_execute(const fftwf_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_execute_dft(p,in,out) bind(C, name='fftwf_execute_dft')
  type(C_PTR), value :: p
  complex(C_FLOAT_COMPLEX), dimension(*), intent(inout) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
end subroutine fftwf_execute_dft
```

Parameters

p Input parameter

`p` is `fftwf_plan`

An FFT plan created from a preceding call

5.7.7 fftwf_execute_dft

`fftwf_execute_dft` executes a previously created FFT plan, however input and output data locations maybe different than those given at planning time.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_execute_dft(const fftwf_plan p, fftwf_complex *in,
                       fftwf_complex *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_execute_dft(p,in,out) bind(C, name='fftwf_execute_dft')
  type(C_PTR), value :: p
  complex(C_FLOAT_COMPLEX), dimension(*), intent(inout) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
end subroutine fftwf_execute_dft
```

Parameters

p Input parameter

p is fftwf_plan

An FFT plan created from a preceding call

in Input parameter

in is fftwf_complex*

in is a pointer to a previously allocated array of data, on which to calculate a complex-to-complex FFT

out Output parameter

out is fftwf_complex*

out is a pointer to a previously allocated array of data, into which to return the results of the complex-to-complex FFT

5.7.8 fftwf_execute_dft_c2r

fftwf_execute_dft_c2r executes a previously created complex-to-real FFT plan, however input and output data locations maybe different than those given at planning time.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_execute_dft_c2r(const fftwf_plan p, fftwf_complex *in,
                           float *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_execute_dft_c2r(p,in,out) bind(C, name='fftwf_execute_dft_c2r')
  type(C_PTR), value :: p
  complex(C_FLOAT_COMPLEX), dimension(*), intent(inout) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
end subroutine fftwf_execute_dft_c2r
```

Parameters

p Input parameter

p is fftwf_plan

An FFT plan created from a preceding call

in Input parameter

in is fftwf_complex*

in is a pointer to a previously allocated array of data, on which to calculate a complex-to-real FFT

out output out is float*

out is a pointer to a previously allocated array of data, into which to return the results of the complex-to-real FFT

5.7.9 fftwf_execute_dft_r2c

`fftwf_execute_dft_r2c` executes a previously created FFT plan, however input and output data locations maybe different than those given at planning time.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_execute_dft_r2c(const fftwf_plan p, float *in,
                           fftwf_complex *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_execute_dft_r2c(p,in,out) &
    bind(C, name='fftwf_execute_dft_r2c')
  type(C_PTR), value :: p
  real(C_FLOAT), dimension(*), intent(inout) :: in
  complex(C_FLOAT_COMPLEX), dimension(*), intent(out) :: out
end subroutine fftwf_execute_dft_r2c
```

Parameters

p Input parameter

`p` is `fftwf_plan`

An FFT plan created from a preceding call

in Input parameter

`in` is `float*`

`in` is a pointer to a previously allocated array of data, on which to calculate a real-to-complex FFT

out Output parameter

`out` is `fftwf_complex*`

`out` is a pointer to a previously allocated array of data, into which to return the results of the real-to-complex FFT

5.7.10 fftwf_execute_r2r

`fftwf_execute_r2r` executes a previously created real-to-real FFT plan, however input and output data locations maybe different than those given at planning time.

Note: Since real-to-real transforms are not currently available in Arm Performance Libraries it is impossible to provide a valid plan, `p`, to pass to this function.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_execute_r2r(const fftwf_plan p, float *in, float *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_execute_r2r(p,in,out) bind(C, name='fftwf_execute_r2r')
  type(C_PTR), value :: p
  real(C_FLOAT), dimension(*), intent(inout) :: in
  real(C_FLOAT), dimension(*), intent(out) :: out
end subroutine fftwf_execute_r2r
```

Parameters

p Input parameter

p is fftwf_plan

An FFT plan created from a preceding call

in Input parameter

in is float*

in is a pointer to a previously allocated array of data, on which to calculate a real-to-real FFT

out Output parameter

out is float*

out is a pointer to a previously allocated array of data, into which to return the results of the real-to-real FFT

5.7.11 fftwh_execute

fftwh_execute executes a previously created FFT plan.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_execute(const fftwh_plan p);
```

Parameters

p Input parameter

p is fftwh_plan

An FFT plan created from a preceding call

5.7.12 fftwh_execute_dft

`fftwh_execute_dft` executes a previously created FFT plan, however input and output data locations maybe different than those given at planning time.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_execute_dft(const fftwh_plan p, fftwh_complex *in,
                       fftwh_complex *out);
```

Parameters

p Input parameter

`p` is `fftwh_plan`

An FFT plan created from a preceding call

in Input parameter

`in` is `fftwh_complex*`

`in` is a pointer to a previously allocated array of data, on which to calculate a complex-to-complex FFT

out Output parameter

`out` is `fftwh_complex*`

`out` is a pointer to a previously allocated array of data, into which to return the results of the complex-to-complex FFT

5.7.13 fftwh_execute_dft_c2r

`fftwh_execute_dft_c2r` executes a previously created complex-to-real FFT plan, however input and output data locations maybe different than those given at planning time.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_execute_dft_c2r(const fftwh_plan p, fftwh_complex *in,
                           __fp16 *out);
```

Parameters

p Input parameter

`p` is `fftwh_plan`

An FFT plan created from a preceding call

in Input parameter

`in` is `fftwh_complex*`

`in` is a pointer to a previously allocated array of data, on which to calculate a complex-to-real FFT

out output `out` is `__fp16*`

`out` is a pointer to a previously allocated array of data, into which to return the results of the complex-to-real FFT

5.7.14 fftwh_execute_dft_r2c

`fftwh_execute_dft_r2c` executes a previously created FFT plan, however input and output data locations maybe different than those given at planning time.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_execute_dft_r2c(const fftwh_plan p, __fp16 *in,
                           fftwh_complex *out);
```

Parameters

p Input parameter

`p` is `fftwh_plan`

An FFT plan created from a preceding call

in Input parameter

`in` is `__fp16*`

`in` is a pointer to a previously allocated array of data, on which to calculate a real-to-complex FFT

out Output parameter

`out` is `fftwh_complex*`

`out` is a pointer to a previously allocated array of data, into which to return the results of the real-to-complex FFT

5.7.15 fftwh_execute_r2r

`fftwh_execute_r2r` executes a previously created real-to-real FFT plan, however input and output data locations maybe different than those given at planning time.

Note: Since real-to-real transforms are not currently available in Arm Performance Libraries it is impossible to provide a valid plan, `p`, to pass to this function.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_execute_r2r(const fftwh_plan p, __fp16 *in, __fp16 *out);
```

Parameters

p Input parameter

`p` is `fftwh_plan`

An FFT plan created from a preceding call

in Input parameter

`in` is `__fp16*`

`in` is a pointer to a previously allocated array of data, on which to calculate a real-to-real FFT

out Output parameter

`out` is `__fp16*`

`out` is a pointer to a previously allocated array of data, into which to return the results of the real-to-real FFT

5.8 FFT memory functions

5.8.1 fftw_alignment_of

`fftw_alignment_of` gives the alignment of a supplied pointer. Multiple invocations with different pointers can be used to check if arrays are aligned similarly.

Syntax

C specification:

```
#include "fftw3.h"

int fftw_alignment_of(double *p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftw_alignment_of(p) &
    bind(C, name='fftw_alignment_of')
  real(C_DOUBLE), dimension(*), intent(out) :: p
end function fftw_alignment_of
```

Returns

`fftw_alignment_of` returns an `int` denoting the alignment of the supplied pointer.

Parameters

p Input parameter

p is double

This is a pointer to a previously allocated array.

5.8.2 fftw_alloc_complex

fftw_alloc_complex allocates a block of data of the requested size.

Syntax

C specification:

```
#include "fftw3.h"

fftw_complex* fftw_alloc_complex(size_t n);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_alloc_complex(n) &
    bind(C, name='fftw_alloc_complex')
  integer(C_SIZE_T), value :: n
end function fftw_alloc_complex
```

Returns

This function returns a pointer, of type fftw_complex*, to an allocated block of memory of the requested size.

Parameters

n Input parameter

n is size_t

This is the size, in terms of number of fftw_complex entries, of array to be created

Constraint: n >= 1

5.8.3 fftw_alloc_real

fftw_alloc_real allocates a block of data of the requested size.

Syntax

C specification:

```
#include "fftw3.h"

double* fftw_alloc_real(size_t n);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_alloc_real(n) bind(C, name='fftw_alloc_real')
  integer(C_SIZE_T), value :: n
end function fftw_alloc_real
```

Returns

This function returns a pointer, of type `double*`, to an allocated block of memory of the requested size.

Parameters

n Input parameter

`n` is `size_t`

This is the size, in terms of number of `double` entries, of array to be created

Constraint: `n` >= 1

5.8.4 fftw_cleanup

`fftw_cleanup` is allowed to invalidate all FFT plans that have been previously created, without freeing memory. We recommend *not* to use this function, and in the current Arm Performance Libraries implementation this function does nothing, returning immediately.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_cleanup(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_cleanup() bind(C, name='fftw_cleanup')
end subroutine fftw_cleanup
```

5.8.5 fftw_destroy_plan

`fftw_destroy_plan` frees all memory associated with the creation of an FFT plan. The plan should not be reused after this call.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_destroy_plan(fftw_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_destroy_plan(p) bind(C, name='fftw_destroy_plan')
  type(C_PTR), value :: p
end subroutine fftw_destroy_plan
```

Parameters

p Input parameter

p is `fftw_plan`

p is a pointer to a previously created plan.

5.8.6 fftw_free

`fftw_free` frees the memory created in a previous malloc() or fftw_malloc() call.

Syntax

C specification:

```
#include "fftw3.h"

void* fftw_free(void *p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_free(p) bind(C, name='fftw_free')
  type(C_PTR), value :: p
end subroutine fftw_free
```

Parameters

p Input parameter

p is `void *`

p is a pointer to a previously created array

5.8.7 fftw_malloc

`fftw_malloc` allocates a block of data of the requested size.

Syntax

C specification:

```
#include "fftw3.h"

void* fftw_malloc(size_t n);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_malloc(n) bind(C, name='fftw_malloc')
  integer(C_SIZE_T), value :: n
end function fftw_malloc
```

Returns

This function returns a pointer, of type `void*`, to an allocated block of memory of the requested size.

Parameters

n Input parameter

`n` is `size_t`

This is the size, in bytes, of array to be created

Constraint: `n0` >= 1

5.8.8 fftwf_alignment_of

`fftwf_alignment_of` gives the alignment of a supplied pointer. Multiple invocations with different pointers can be used to check if arrays are aligned similarly.

Syntax

C specification:

```
#include "fftw3.h"

int fftwf_alignment_of(float *p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftwf_alignment_of(p) &
    bind(C, name='fftwf_alignment_of')
  real(C_FLOAT), dimension(*), intent(out) :: p
end function fftwf_alignment_of
```

Returns

`fftwf_alignment_of` returns an `int` denoting the alignment of the supplied pointer.

Parameters

p Input parameter

`p` is `float`

This is a pointer to a previously allocated array.

5.8.9 fftwf_alloc_complex

`fftwf_alloc_complex` allocates a block of data of the requested size.

Syntax

C specification:

```
#include "fftw3.h"

fftwf_complex* fftwf_alloc_complex(size_t n);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_alloc_complex(n) &
    bind(C, name='fftwf_alloc_complex')
  integer(C_SIZE_T), value :: n
end function fftwf_alloc_complex
```

Returns

This function returns a pointer, of type `fftwf_complex*`, to an allocated block of memory of the requested size.

Parameters

n Input parameter

`n` is `size_t`

This is the size, in terms of number of `fftwf_complex` entries, of array to be created

Constraint: `n` >= 1

5.8.10 fftwf_alloc_real

`fftwf_alloc_real` allocates a block of data of the requested size.

Syntax

C specification:

```
#include "fftw3.h"

float* fftwf_alloc_real(size_t n);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_alloc_real(n) bind(C, name='fftwf_alloc_real')
  integer(C_SIZE_T), value :: n
end function fftwf_alloc_real
```

Returns

This function returns a pointer, of type `float*`, to an allocated block of memory of the requested size.

Parameters

n Input parameter

`n` is `size_t`

This is the size, in terms of number of `float` entries, of array to be created

Constraint: `n` >= 1

5.8.11 fftwf_cleanup

`fftwf_cleanup` is allowed to invalidate all FFT plans that have been previously created, without freeing memory. We recommend *not* to use this function, and in the current Arm Performance Libraries implementation this function does nothing, returning immediately.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_cleanup(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_cleanup() bind(C, name='fftwf_cleanup')
end subroutine fftwf_cleanup
```

5.8.12 fftwf_destroy_plan

`fftwf_destroy_plan` frees all memory associated with the creation of an FFT plan. The plan should not be reused after this call.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_destroy_plan(fftwf_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_destroy_plan(p) bind(C, name='fftwf_destroy_plan')
  type(C_PTR), value :: p
end subroutine fftwf_destroy_plan
```

Parameters

p Input parameter

p is fftwf_plan

p is a pointer to a previously created plan.

5.8.13 fftwf_free

fftwf_free frees the memory created in a previous malloc() or fftwf_malloc() call.

Syntax

C specification:

```
#include "fftw3.h"

void* fftwf_free(void *p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_free(p) bind(C, name='fftwf_free')
  type(C_PTR), value :: p
end subroutine fftwf_free
```

Parameters

p Input parameter

p is void *

p is a pointer to a previously created array

5.8.14 fftwf_malloc

fftwf_malloc allocates a block of data of the requested size.

Syntax

C specification:

```
#include "fftw3.h"

void* fftwf_malloc(size_t n);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_malloc(n) bind(C, name='fftwf_malloc')
  integer(C_SIZE_T), value :: n
end function fftwf_malloc
```

Returns

This function returns a pointer, of type `void*`, to an allocated block of memory of the requested size.

Parameters

n Input parameter

`n` is `size_t`

This is the size, in bytes, of array to be created

Constraint: `n0` >= 1

5.8.15 fftwh_alignment_of

`fftwh_alignment_of` gives the alignment of a supplied pointer. Multiple invocations with different pointers can be used to check if arrays are aligned similarly.

Syntax

C specification:

```
#include "fftw3.h"

int fftwh_alignment_of(__fp16 *p);
```

Returns

`fftwh_alignment_of` returns an `int` denoting the alignment of the supplied pointer.

Parameters

p Input parameter

`p` is `__fp16`

This is a pointer to a previously allocated array.

5.8.16 fftwh_alloc_complex

`fftwh_alloc_complex` allocates a block of data of the requested size.

Syntax

C specification:

```
#include "fftw3.h"

fftwh_complex* fftwh_alloc_complex(size_t n);
```

Returns

This function returns a pointer, of type `fftwh_complex*`, to an allocated block of memory of the requested size.

Parameters

n Input parameter

n is size_t

This is the size, in terms of number of fftwh_complex entries, of array to be created

Constraint: n >= 1

5.8.17 fftwh_alloc_real

fftwh_alloc_real allocates a block of data of the requested size.

Syntax

C specification:

```
#include "fftw3.h"

__fp16* fftwh_alloc_real(size_t n);
```

Returns

This function returns a pointer, of type __fp16*, to an allocated block of memory of the requested size.

Parameters

n Input parameter

n is size_t

This is the size, in terms of number of __fp16 entries, of array to be created

Constraint: n >= 1

5.8.18 fftwh_cleanup

fftwh_cleanup is allowed to invalidate all FFT plans that have been previously created, without freeing memory. We recommend *not* to use this function, and in the current Arm Performance Libraries implementation this function does nothing, returning immediately.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_cleanup(void);
```

5.8.19 fftwh_destroy_plan

fftwh_destroy_plan frees all memory associated with the creation of an FFT plan. The plan should not be reused after this call.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_destroy_plan(fftwh_plan p);
```

Parameters

p Input parameter

p is `fftwh_plan`

p is a pointer to a previously created plan.

5.8.20 fftwh_free

`fftwh_free` frees the memory created in a previous malloc() or fftwh_malloc() call.

Syntax

C specification:

```
#include "fftw3.h"

void* fftwh_free(void *p);
```

Parameters

p Input parameter

p is `void *`

p is a pointer to a previously created array

5.8.21 fftwh_malloc

`fftwh_malloc` allocates a block of data of the requested size.

Syntax

C specification:

```
#include "fftw3.h"

void* fftwh_malloc(size_t n);
```

Returns

This function returns a pointer, of type `void*`, to an allocated block of memory of the requested size.

Parameters

n Input parameter

n is size_t

This is the size, in bytes, of array to be created

Constraint: n0 >= 1

5.9 FFT wisdom functions

5.9.1 fftw_export_wisdom

fftw_export_wisdom calls the user-supplied function to write Arm Performance Libraries FFT wisdom out, one character at a time.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_export_wisdom(void (*write_char)(char c, void *), void *data);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_export_wisdom(write_char,data) &
    bind(C, name='fftw_export_wisdom')
  type(C_FUNPTR), value :: write_char
  type(C_PTR), value :: data
end subroutine fftw_export_wisdom
```

Parameters

write_char Input parameter

write_char is a pointer to a function that will write out the wisdom accumulated by the program, one character at a time

Constraint: write_char takes two parameters:

the first is a char which is the character to be written

the second is a pointer to where this data is to be written. Examples of using this would be a FILE*, an array or unused and just writing to the screen

data Input parameter

data is a void * pointer that is itself passed as the second parameter to the function write_char

5.9.2 fftw_export_wisdom_to_file

fftw_export_wisdom_to_file exports the currently known Arm Performance Libraries FFT wisdom to the file opened as output_file specified by the user. Note that this routine expects a file pointer to an already open file, rather than *_armpl_fftw_export_wisdom_to_filname* which opens a new file with the supplied name.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_export_wisdom_to_file(FILE *output_file);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_export_wisdom_to_file(output_file) &
    bind(C, name='fftw_export_wisdom_to_file')
  type(C_PTR), value :: output_file
end subroutine fftw_export_wisdom_to_file
```

Parameters

output_file Input parameter

`output_file` is `FILE *`

`output_file` is a pointer to a previously opened file.

Constraint: The file pointer `output_file` must be opened previous to calling `fftw_export_wisdom_to_file`.

5.9.3 _armpl_fftw_export_wisdom_to_filname

`fftw_export_wisdom_to_filename` exports the currently known Arm Performance Libraries FFT wisdom to a new file called `output_file` specified by the user. Note that this routine opens a new file with the supplied name, rather than *fftw_export_wisdom_to_file* which expects a file pointer to an already open file.

Syntax

C specification:

```
#include "fftw3.h"

int fftw_export_wisdom_to_filename(const char *filename);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftw_export_wisdom_to_filename(filename) &
    bind(C, name='fftw_export_wisdom_to_filename')
  character(C_CHAR), dimension(*), intent(in) :: filename
end function fftw_export_wisdom_to_filename
```

Returns

If the wisdom file is successfully created, the function returns `1`. Otherwise, the function returns `0`.

Parameters

`filename` Input parameter

`filename` is `const char *`

`filename` is a pointer to an array storing the name of the file to be opened

5.9.4 fftw_export_wisdom_to_string

`fftw_export_wisdom_to_string` exports the currently known Arm Performance Libraries FFT wisdom to a character string to be returned to the user.

Syntax

C specification:

```
#include "fftw3.h"

char *fftw_export_wisdom_to_string(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftw_export_wisdom_to_string() &
    bind(C, name='fftw_export_wisdom_to_string')
end function fftw_export_wisdom_to_string
```

Returns

`fftw_export_wisdom_to_string` returns a pointer to a string containing the previously collected wisdom.

5.9.5 fftw_forget_wisdom

`fftw_forget_wisdom` is intended to allow a user to discard previously loaded or learned wisdom. At present, in the Arm Performance Libraries implementation no action is taken, and the function returns no error.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_forget_wisdom(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_forget_wisdom() bind(C, name='fftw_forget_wisdom')
end subroutine fftw_forget_wisdom
```

Returns

`fftw_forget_wisdom` always returns 0.

5.9.6 fftw_import_system_wisdom

`fftw_import_system_wisdom` reads previously written Arm Performance Libraries FFT wisdom from a default system file. At present, system wisdom is unavailable for Arm Performance Libraries and this function will return 0.

Syntax

C specification:

```
#include "fftw3.h"

int fftw_import_system_wisdom(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftw_import_system_wisdom() &
    bind(C, name='fftw_import_system_wisdom')
end function fftw_import_system_wisdom
```

Returns

`fftw_import_system_wisdom` returns either 0 indicating that the system wisdom file was read correctly, or 1 otherwise. However since system wisdom is currently unavailable for Arm Performance Libraries, this function will return 0.

5.9.7 fftw_import_wisdom

`fftw_import_wisdom` calls the user-supplied function to read Arm Performance Libraries FFT wisdom in, one character at a time.

Syntax

C specification:

```
#include "fftw3.h"

int fftw_import_wisdom(int (*read_char)(void *), void *data);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftw_import_wisdom(read_char,data) &
    bind(C, name='fftw_import_wisdom')
  type(C_FUNPTR), value :: read_char
  type(C_PTR), value :: data
end function fftw_import_wisdom
```

Returns

`fftw_import_wisdom` returns either 0 indicating that the wisdom was read correctly, or 1 otherwise.

Parameters

`read_char` Input parameter

`read_char` is a pointer to a function that will read in the wisdom, one character at a time

Constraint: `write_char` takes two parameters:

the first is a `char` which is the character to be read

the second is a pointer to where this data should be read. Examples of using this would be a `FILE*` or an array

`data` Input parameter

`data` is a `void * pointer that is itself passed as the second parameter to the function ``read_char`

5.9.8 fftw_import_wisdom_from_file

`fftw_import_wisdom_from_file` reads the previously written Arm Performance Libraries FFT wisdom from the file open as `input_file`.

Syntax

C specification:

```
#include "fftw3.h"

int fftw_import_wisdom_from_file(FILE *input_file);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftw_import_wisdom_from_file(input_file) &
    bind(C, name='fftw_import_wisdom_from_file')
  type(C_PTR), value :: input_file
end function fftw_import_wisdom_from_file
```

Returns

`fftw_import_wisdom_from_file` returns either 0 indicating that the wisdom file was read correctly, or 1 otherwise

Parameters

`input_file` Input parameter

`input_file` is `FILE *`

`input_file` is a pointer to a previously created a file of Arm Performance Libraries FFT wisdom

5.9.9 fftw_import_wisdom_from_filename

`fftw_import_wisdom_from_filename` reads the previously written Arm Performance Libraries FFT wisdom from a file called `input_file`.

Syntax

C specification:

```
#include "fftw3.h"

int fftw_import_wisdom_from_filename(const char *filename);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftw_import_wisdom_from_filename(filename) &
    bind(C, name='fftw_import_wisdom_from_filename')
  character(C_CHAR), dimension(*), intent(in) :: filename
end function fftw_import_wisdom_from_filename
```

Returns

`fftw_import_wisdom_from_filename` returns either 0 indicating that the wisdom file was read correctly, or 1 otherwise

Parameters

`filename` Input parameter

`filename` is `const char *`

`filename` provides the name of the file from which wisdom will be loaded

5.9.10 fftw_import_wisdom_from_string

`fftw_import_wisdom_from_string` reads the previously written Arm Performance Libraries FFT wisdom from a string given by `input_string`.

Syntax

C specification:

```
#include "fftw3.h"

int fftw_import_wisdom_from_string(const char *input_string);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftw_import_wisdom_from_string(input_string) &
    bind(C, name='fftw_import_wisdom_from_string')
```

(continues on next page)

(continued from previous page)

```
  character(C_CHAR), dimension(*), intent(in) :: input_string
end function fftw_import_wisdom_from_string
```

Returns

`fftw_import_wisdom_from_string` returns either 0 indicating that the wisdom file was read correctly, or 1 otherwise

Parameters

`input_string` Input parameter

`input_string` is `const char *`

`input_string` is a pointer to a previously created string from which the accumulated wisdom will be read

5.9.11 fftwf_export_wisdom

`fftwf_export_wisdom` calls the user-supplied function to write Arm Performance Libraries FFT wisdom out, one character at a time.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_export_wisdom(void (*write_char)(char c, void *), void *data);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_export_wisdom(write_char,data) &
    bind(C, name='fftwf_export_wisdom')
  type(C_FUNPTR), value :: write_char
  type(C_PTR), value :: data
end subroutine fftwf_export_wisdom
```

Parameters

`write_char` Input parameter

`write_char` is a pointer to a function that will write out the wisdom accumulated by the program, one character at a time

Constraint: `write_char` takes two parameters:

the first is a `char` which is the character to be written

the second is a pointer to where this data is to be written. Examples of using this would be a `FILE*`, an array or unused and just writing to the screen

`data` Input parameter

`data` is a `void *` pointer that is itself passed as the second parameter to the function `write_char`

5.9.12 fftwf_export_wisdom_to_file

`fftwf_export_wisdom_to_file` exports the currently known Arm Performance Libraries FFT wisdom to the file opened as `output_file` specified by the user. Note that this routine expects a file pointer to an already open file, rather than *_armpl_fftwf_export_wisdom_to_filname* which opens a new file with the supplied name.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_export_wisdom_to_file(FILE *output_file);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_export_wisdom_to_file(output_file) &
    bind(C, name='fftwf_export_wisdom_to_file')
  type(C_PTR), value :: output_file
end subroutine fftwf_export_wisdom_to_file
```

Parameters

`output_file` Input parameter

`output_file` is `FILE *`

`output_file` is a pointer to a previously opened file.

Constraint: The file pointer `output_file` must be opened previous to calling `fftwf_export_wisdom_to_file`.

5.9.13 _armpl_fftwf_export_wisdom_to_filname

`fftwf_export_wisdom_to_filename` exports the currently known Arm Performance Libraries FFT wisdom to a new file called `output_file` specified by the user. Note that this routine opens a new file with the supplied name, rather than *fftwf_export_wisdom_to_file* which expects a file pointer to an already open file.

Syntax

C specification:

```
#include "fftw3.h"

int fftwf_export_wisdom_to_filename(const char *filename);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftwf_export_wisdom_to_filename(filename) &
    bind(C, name='fftwf_export_wisdom_to_filename')
  character(C_CHAR), dimension(*), intent(in) :: filename
end function fftwf_export_wisdom_to_filename
```

Returns

If the wisdom file is successfully created, the function returns `1`. Otherwise, the function returns `0`.

Parameters

`filename` Input parameter

`filename` is `const char *`

`filename` is a pointer to an array storing the name of the file to be opened

5.9.14 fftwf_export_wisdom_to_string

`fftwf_export_wisdom_to_string` exports the currently known Arm Performance Libraries FFT wisdom to a character string to be returned to the user.

Syntax

C specification:

```
#include "fftw3.h"

char *fftwf_export_wisdom_to_string(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

type(C_PTR) function fftwf_export_wisdom_to_string() &
    bind(C, name='fftwf_export_wisdom_to_string')
end function fftwf_export_wisdom_to_string
```

Returns

`fftwf_export_wisdom_to_string` returns a pointer to a string containing the previously collected wisdom.

5.9.15 fftwf_forget_wisdom

`fftwf_forget_wisdom` is intended to allow a user to discard previously loaded or learned wisdom. At present, in the Arm Performance Libraries implementation no action is taken, and the function returns no error.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_forget_wisdom(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_forget_wisdom() bind(C, name='fftwf_forget_wisdom')
end subroutine fftwf_forget_wisdom
```

Returns

`fftwf_forget_wisdom` always returns 0.

5.9.16 fftwf_import_system_wisdom

`fftwf_import_system_wisdom` reads previously written Arm Performance Libraries FFT wisdom from a default system file. At present, system wisdom is unavailable for Arm Performance Libraries and this function will return 0.

Syntax

C specification:

```
#include "fftw3.h"

int fftwf_import_system_wisdom(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftwf_import_system_wisdom() &
    bind(C, name='fftwf_import_system_wisdom')
end function fftwf_import_system_wisdom
```

Returns

`fftwf_import_system_wisdom` returns either 0 indicating that the system wisdom file was read correctly, or 1 otherwise. However since system wisdom is currently unavailable for Arm Performance Libraries, this function will return 0.

5.9.17 fftwf_import_wisdom

`fftwf_import_wisdom` calls the user-supplied function to read Arm Performance Libraries FFT wisdom in, one character at a time.

Syntax

C specification:

```
#include "fftw3.h"

int fftwf_import_wisdom(int (*read_char)(void *), void *data);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftwf_import_wisdom(read_char,data) &
    bind(C, name='fftwf_import_wisdom')
  type(C_FUNPTR), value :: read_char
  type(C_PTR), value :: data
end function fftwf_import_wisdom
```

Returns

`fftwf_import_wisdom` returns either 0 indicating that the wisdom was read correctly, or 1 otherwise.

Parameters

`read_char` Input parameter

`read_char` is a pointer to a function that will read in the wisdom, one character at a time

Constraint: `write_char` takes two parameters:

the first is a `char` which is the character to be read

the second is a pointer to where this data should be read. Examples of using this would be a `FILE*` or an array

`data` Input parameter

`data` is a `void * pointer that is itself passed as the second parameter to the function ``read_char`

5.9.18 fftwf_import_wisdom_from_file

`fftwf_import_wisdom_from_file` reads the previously written Arm Performance Libraries FFT wisdom from the file open as `input_file`.

Syntax

C specification:

```
#include "fftw3.h"

int fftwf_import_wisdom_from_file(FILE *input_file);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftwf_import_wisdom_from_file(input_file) &
    bind(C, name='fftwf_import_wisdom_from_file')
  type(C_PTR), value :: input_file
end function fftwf_import_wisdom_from_file
```

Returns

`fftwf_import_wisdom_from_file` returns either 0 indicating that the wisdom file was read correctly, or 1 otherwise

Parameters

input_file Input parameter

input_file is FILE *

input_file is a pointer to a previously created a file of Arm Performance Libraries FFT wisdom

5.9.19 fftwf_import_wisdom_from_filename

fftwf_import_wisdom_from_filename reads the previously written Arm Performance Libraries FFT wisdom from a file called input_file.

Syntax

C specification:

```
#include "fftw3.h"

int fftwf_import_wisdom_from_filename(const char *filename);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftwf_import_wisdom_from_filename(filename) &
    bind(C, name='fftwf_import_wisdom_from_filename')
  character(C_CHAR), dimension(*), intent(in) :: filename
end function fftwf_import_wisdom_from_filename
```

Returns

fftwf_import_wisdom_from_filename returns either 0 indicating that the wisdom file was read correctly, or 1 otherwise

Parameters

filename Input parameter

filename is const char *

filename provides the name of the file from which wisdom will be loaded

5.9.20 fftwf_import_wisdom_from_string

fftwf_import_wisdom_from_string reads the previously written Arm Performance Libraries FFT wisdom from a string given by input_string.

Syntax

C specification:

```
#include "fftw3.h"

int fftwf_import_wisdom_from_string(const char *input_string);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftwf_import_wisdom_from_string(input_string) &
    bind(C, name='fftwf_import_wisdom_from_string')
  character(C_CHAR), dimension(*), intent(in) :: input_string
end function fftwf_import_wisdom_from_string
```

Returns

`fftwf_import_wisdom_from_string` returns either 0 indicating that the wisdom file was read correctly, or 1 otherwise

Parameters

`input_string` Input parameter

`input_string` is `const char *`

`input_string` is a pointer to a previously created string from which the accumulated wisdom will be read

5.9.21 fftwh_export_wisdom

`fftwh_export_wisdom` calls the user-supplied function to write Arm Performance Libraries FFT wisdom out, one character at a time.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_export_wisdom(void (*write_char)(char c, void *), void *data);
```

Parameters

`write_char` Input parameter

`write_char` is a pointer to a function that will write out the wisdom accumulated by the program, one character at a time

Constraint: `write_char` takes two parameters:

the first is a `char` which is the character to be written

the second is a pointer to where this data is to be written. Examples of using this would be a `FILE*`, an array or unused and just writing to the screen

`data` Input parameter

`data` is a `void *` pointer that is itself passed as the second parameter to the function `write_char`

5.9.22 fftwh_export_wisdom_to_file

`fftwh_export_wisdom_to_file` exports the currently known Arm Performance Libraries FFT wisdom to the file opened as `output_file` specified by the user. Note that this routine expects a file pointer to an already open file, rather than *_armpl_fftwh_export_wisdom_to_filname* which opens a new file with the supplied name.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_export_wisdom_to_file(FILE *output_file);
```

Parameters

`output_file` Input parameter

`output_file` is `FILE *`

`output_file` is a pointer to a previously opened file.

Constraint: The file pointer `output_file` must be opened previous to calling `fftwh_export_wisdom_to_file`.

5.9.23 _armpl_fftwh_export_wisdom_to_filname

`fftwh_export_wisdom_to_filename` exports the currently known Arm Performance Libraries FFT wisdom to a new file called `output_file` specified by the user. Note that this routine opens a new file with the supplied name, rather than *fftwh_export_wisdom_to_file* which expects a file pointer to an already open file.

Syntax

C specification:

```
#include "fftw3.h"

int fftwh_export_wisdom_to_filename(const char *filename);
```

Returns

If the wisdom file is successfully created, the function returns `1`. Otherwise, the function returns `0`.

Parameters

`filename` Input parameter

`filename` is `const char *`

`filename` is a pointer to an array storing the name of the file to be opened

5.9.24 fftwh_export_wisdom_to_string

`fftwh_export_wisdom_to_string` exports the currently known Arm Performance Libraries FFT wisdom to a character string to be returned to the user.

Syntax

C specification:

```
#include "fftw3.h"

char *fftwh_export_wisdom_to_string(void);
```

Returns

`fftwh_export_wisdom_to_string` returns a pointer to a string containing the previously collected wisdom.

5.9.25 fftwh_forget_wisdom

`fftwh_forget_wisdom` is intended to allow a user to discard previously loaded or learned wisdom. At present, in the Arm Performance Libraries implementation no action is taken, and the function returns no error.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_forget_wisdom(void);
```

Returns

`fftwh_forget_wisdom` always returns 0.

5.9.26 fftwh_import_system_wisdom

`fftwh_import_system_wisdom` reads previously written Arm Performance Libraries FFT wisdom from a default system file. At present, system wisdom is unavailable for Arm Performance Libraries and this function will return 0.

Syntax

C specification:

```
#include "fftw3.h"

int fftwh_import_system_wisdom(void);
```

Returns

`fftwh_import_system_wisdom` returns either 0 indicating that the system wisdom file was read correctly, or 1 otherwise. However since system wisdom is currently unavailable for Arm Performance Libraries, this function will return 0.

5.9.27 fftwh_import_wisdom

`fftwh_import_wisdom` calls the user-supplied function to read Arm Performance Libraries FFT wisdom in, one character at a time.

Syntax

C specification:

```
#include "fftw3.h"

int fftwh_import_wisdom(int (*read_char)(void *), void *data);
```

Returns

`fftwh_import_wisdom` returns either 0 indicating that the wisdom was read correctly, or 1 otherwise.

Parameters

`read_char` Input parameter

`read_char` is a pointer to a function that will read in the wisdom, one character at a time

Constraint: `write_char` takes two parameters:

the first is a `char` which is the character to be read

the second is a pointer to where this data should be read. Examples of using this would be a `FILE*` or an array

`data` Input parameter

`data` is a `void * pointer that is itself passed as the second parameter to the function ``read_char`

5.9.28 fftwh_import_wisdom_from_file

`fftwh_import_wisdom_from_file` reads the previously written Arm Performance Libraries FFT wisdom from the file open as `input_file`.

Syntax

C specification:

```
#include "fftw3.h"

int fftwh_import_wisdom_from_file(FILE *input_file);
```

Returns

`fftwh_import_wisdom_from_file` returns either 0 indicating that the wisdom file was read correctly, or 1 otherwise

Parameters

input_file Input parameter

input_file is FILE *

input_file is a pointer to a previously created a file of Arm Performance Libraries FFT wisdom

5.9.29 fftwh_import_wisdom_from_filename

fftwh_import_wisdom_from_filename reads the previously written Arm Performance Libraries FFT wisdom from a file called input_file.

Syntax

C specification:

```
#include "fftw3.h"

int fftwh_import_wisdom_from_filename(const char *filename);
```

Returns

fftwh_import_wisdom_from_filename returns either 0 indicating that the wisdom file was read correctly, or 1 otherwise

Parameters

filename Input parameter

filename is const char *

filename provides the name of the file from which wisdom will be loaded

5.9.30 fftwh_import_wisdom_from_string

fftwh_import_wisdom_from_string reads the previously written Arm Performance Libraries FFT wisdom from a string given by input_string.

Syntax

C specification:

```
#include "fftw3.h"

int fftwh_import_wisdom_from_string(const char *input_string);
```

Returns

fftwh_import_wisdom_from_string returns either 0 indicating that the wisdom file was read correctly, or 1 otherwise

Parameters

input_string Input parameter

`input_string` is `const char *`

`input_string` is a pointer to a previously created string from which the accumulated wisdom will be read

5.10 FFT threading functions

5.10.1 fftw_cleanup_threads

`fftw_cleanup_threads` is intended to allow a user to discard memory and wisdom from running threaded plans previously. In the Arm Performance Libraries implementation no action is taken, since users will be using OpenMP for threading. Wisdom is stored such that the thread-count used does not invalidated wisdom with different numbers of threads.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_cleanup_threads(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_cleanup_threads() bind(C, name='fftw_cleanup_threads')
end subroutine fftw_cleanup_threads
```

5.10.2 fftw_init_threads

`fftw_init_threads` is intended to allow a user to initialise the use of threading in the execution of FFTs. In the Arm Performance Libraries implementation threads are always ready for use, provided a suitable variety has been linked in when the application was compiled. This function, therefore takes no further action, and the function returns no error.

Syntax

C specification:

```
#include "fftw3.h"

int fftw_init_threads(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftw_init_threads() &
    bind(C, name='fftw_init_threads')
end function fftw_init_threads
```

Returns

`fftw_init_threads` always returns 1.

5.10.3 fftw_make_planner_thread_safe

`fftw_make_planner_thread_safe` is unnecessary in the Arm Performance Libraries implementation since all planning is thread-safe.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_make_planner_thread_safe();
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_make_planner_thread_safe() &
    bind(C, name='fftw_make_planner_thread_safe')
end subroutine fftw_make_planner_thread_safe
```

5.10.4 fftw_plan_with_nthreads

`fftw_plan_with_nthreads` is intended to allow a user to specify the number of threads used for the execution of FFTs. In the Arm Performance Libraries implementation threads are always ready for use, provided a suitable variety has been linked in when the application was compiled. The number of threads to be used is controlled through the usual OpenMP commands. At present this function takes no further control of setting thread counts.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_plan_with_nthreads(int nthreads);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_plan_with_nthreads(nthreads) &
    bind(C, name='fftw_plan_with_nthreads')
  integer(C_INT), value :: nthreads
end subroutine fftw_plan_with_nthreads
```

Parameters

`nthreads` Input parameter

`nthreads` is `int`

This is the number of threads requested to be used when executing subsequent FFT plans

Constraint: `nthreads` >= 1

Note: This value is currently ignored

5.10.5 fftwf_cleanup_threads

`fftwf_cleanup_threads` is intended to allow a user to discard memory and wisdom from running threaded plans previously. In the Arm Performance Libraries implementation no action is taken, since users will be using OpenMP for threading. Wisdom is stored such that the thread-count used does not invalidated wisdom with different numbers of threads.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_cleanup_threads(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_cleanup_threads() bind(C, name='fftwf_cleanup_threads')
end subroutine fftwf_cleanup_threads
```

5.10.6 fftwf_init_threads

`fftwf_init_threads` is intended to allow a user to initialise the use of threading in the execution of FFTs. In the Arm Performance Libraries implementation threads are always ready for use, provided a suitable variety has been linked in when the application was compiled. This function, therefore takes no further action, and the function returns no error.

Syntax

C specification:

```
#include "fftw3.h"

int fftwf_init_threads(void);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

integer(C_INT) function fftwf_init_threads() &
    bind(C, name='fftwf_init_threads')
end function fftwf_init_threads
```

Returns

`fftwf_init_threads` always returns 1.

5.10.7 fftwf_make_planner_thread_safe

`fftwf_make_planner_thread_safe` is unnecessary in the Arm Performance Libraries implementation since all planning is thread-safe.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_make_planner_thread_safe();
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_make_planner_thread_safe() &
    bind(C, name='fftwf_make_planner_thread_safe')
end subroutine fftwf_make_planner_thread_safe
```

5.10.8 fftwf_plan_with_nthreads

`fftwf_plan_with_nthreads` is intended to allow a user to specify the number of threads used for the execution of FFTs. In the Arm Performance Libraries implementation threads are always ready for use, provided a suitable variety has been linked in when the application was compiled. The number of threads to be used is controlled through the usual OpenMP commands. At present this function takes no further control of setting thread counts.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_plan_with_nthreads(int nthreads);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_plan_with_nthreads(nthreads) &
    bind(C, name='fftwf_plan_with_nthreads')
  integer(C_INT), value :: nthreads
end subroutine fftwf_plan_with_nthreads
```

Parameters

nthreads Input parameter

`nthreads` is `int`

This is the number of threads requested to be used when executing subsequent FFT plans

Constraint: `nthreads` >= 1

Note: This value is currently ignored

5.10.9 fftwh_cleanup_threads

`fftwh_cleanup_threads` is intended to allow a user to discard memory and wisdom from running threaded plans previously. In the Arm Performance Libraries implementation no action is taken, since users will be using OpenMP for threading. Wisdom is stored such that the thread-count used does not invalidated wisdom with different numbers of threads.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_cleanup_threads(void);
```

5.10.10 fftwh_init_threads

`fftwh_init_threads` is intended to allow a user to initialise the use of threading in the execution of FFTs. In the Arm Performance Libraries implementation threads are always ready for use, provided a suitable variety has been linked in when the application was compiled. This function, therefore takes no further action, and the function returns no error.

Syntax

C specification:

```
#include "fftw3.h"

int fftwh_init_threads(void);
```

Returns

`fftwh_init_threads` always returns 1.

5.10.11 fftwh_make_planner_thread_safe

`fftwh_make_planner_thread_safe` is unnecessary in the Arm Performance Libraries implementation since all planning is thread-safe.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_make_planner_thread_safe();
```

5.10.12 fftwh_plan_with_nthreads

`fftwh_plan_with_nthreads` is intended to allow a user to specify the number of threads used for the execution of FFTs. In the Arm Performance Libraries implementation threads are always ready for use, provided a suitable variety has been linked in when the application was compiled. The number of threads to be used is controlled through the usual OpenMP commands. At present this function takes no further control of setting thread counts.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_plan_with_nthreads(int nthreads);
```

Parameters

`nthreads` Input parameter

`nthreads` is `int`

This is the number of threads requested to be used when executing subsequent FFT plans

Constraint: `nthreads` >= 1

Note: This value is currently ignored

5.11 FFT utilities functions

5.11.1 fftw_cost

`fftw_cost` provides a measure of the estimated work in executing an FFT plan. In Arm Performance Libraries all costs are currently returned as 0.0.

Syntax

C specification:

```
#include "fftw3.h"

double fftw_cost(const fftw_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

real(C_DOUBLE) function fftw_cost(p) bind(C, name='fftw_cost')
  type(C_PTR), value :: p
end function fftw_cost
```

Returns

`fftw_cost` always returns 0.0.

Parameters

p Input parameter

`p` is `fftw_plan`

An FFT plan created from a preceding call

5.11.2 fftw_estimate_cost

`fftw_estimate_cost` provides a measure of the estimated work in executing an FFT plan. In Arm Performance Libraries all costs are currently returned as 0.0.

Syntax

C specification:

```
#include "fftw3.h"

double fftw_estimate_cost(const fftw_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

real(C_DOUBLE) function fftw_estimate_cost(p) &
    bind(C, name='fftw_estimate_cost')
  type(C_PTR), value :: p
end function fftw_estimate_cost
```

Returns

`fftw_estimate_cost` always returns 0.0.

Parameters

p Input parameter

`p` is `fftw_plan`

An FFT plan created from a preceding call

5.11.3 fftw_flops

`fftw_flops` provides a measure of the number of adds, multiplies and FMAs done during execution of an FFT plan. In Arm Performance Libraries all costs are currently returned as 0.0.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_flops(const fftw_plan plan, double *add, double *mul, double *fma);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_flops(p,add,mul,fmas) bind(C, name='fftw_flops')
  type(C_PTR), value :: p
  real(C_DOUBLE), intent(out) :: add
  real(C_DOUBLE), intent(out) :: mul
  real(C_DOUBLE), intent(out) :: fmas
end subroutine fftw_flops

real(C_DOUBLE) function fftw_estimate_cost(p) &
    bind(C, name='fftw_estimate_cost')
  type(C_PTR), value :: p
end function fftw_estimate_cost
```

Parameters

p Input parameter

`p` is `fftw_plan`

An FFT plan created from a preceding call

add Input parameter

`add` is a `double*`

`add` is a pointer to a single `double` value into which the number of adds is returned

mul Input parameter

`mul` is a `double*`

`mul` is a pointer to a single `double` value into which the number of multiplies is returned

fma Input parameter

`fma` is a `double*`

`fma` is a pointer to a single `double` value into which the number of FMAs is returned

5.11.4 fftw_fprint_plan

`fftw_fprint_plan` is indended to provide a method of printing an FFT plan to a previously opened file. In Arm Performance Libraries this functionality is currently not supported, and a warning message will be printed to STDERR instead.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_fprint_plan(const fftw_plan plan, FILE *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_fprint_plan(p,output_file) bind(C, name='fftw_fprint_plan')
  type(C_PTR), value :: p
  type(C_PTR), value :: output_file
end subroutine fftw_fprint_plan
```

Parameters

p Input parameter

p is fftw_plan

An FFT plan created from a preceding call

out Input parameter

out is FILE *

out is a pointer to a previously opened file.

Constraint: The file pointer output_file must be opened previous to calling fftw_fprintf_plan.

5.11.5 fftw_print_plan

fftw_print_plan is indended to provide a method of printing an FFT plan to STDOUT. In Arm Performance Libraries this functionality is currently not supported, and a warning message will be printed to STDERR instead.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_print_plan(const fftw_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_print_plan(p) bind(C, name='fftw_print_plan')
  type(C_PTR), value :: p
end subroutine fftw_print_plan
```

Parameters

p Input parameter

p is fftw_plan

An FFT plan created from a preceding call

5.11.6 fftw_set_timelimit

fftw_set_timelimit sets a recommended maximum time that should be used in planning FFT transforms. The Arm Performance Libraries implementation uses this as a guideline, stopping once the allowed time has been exhausted, or if it expects further planning to take it over this limit. The use of planning flags, e.g. FFTW_EXHAUSTIVE and friends, are all truncated at this time limit.

To unset the timelimit pass in FFTW_NO_TIMELIMIT to seconds.

Syntax

C specification:

```
#include "fftw3.h"

void fftw_set_timelimit(double seconds);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftw_set_timelimit(t) bind(C, name='fftw_set_timelimit')
  real(C_DOUBLE), value :: t
end subroutine fftw_set_timelimit
```

Parameters

seconds Input parameter

seconds is a double

seconds is a the maximum number of seconds for which the planning time for subsequent FFT plans will be limited.

Note: Pass in FFTW_NO_TIMELIMIT to unset this limit

5.11.7 fftwf_cost

fftwf_cost provides a measure of the estimated work in executing an FFT plan. In Arm Performance Libraries all costs are currently returned as 0.0.

Syntax

C specification:

```
#include "fftw3.h"

double fftwf_cost(const fftwf_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

real(C_DOUBLE) function fftwf_cost(p) bind(C, name='fftwf_cost')
  type(C_PTR), value :: p
end function fftwf_cost
```

Returns

`fftwf_cost` always returns 0.0.

Parameters

p Input parameter

`p` is `fftwf_plan`

An FFT plan created from a preceding call

5.11.8 fftwf_estimate_cost

`fftwf_estimate_cost` provides a measure of the estimated work in executing an FFT plan. In Arm Performance Libraries all costs are currently returned as 0.0.

Syntax

C specification:

```
#include "fftw3.h"

double fftwf_estimate_cost(const fftwf_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

real(C_DOUBLE) function fftwf_estimate_cost(p) bind(C, name='fftwf_estimate_cost')
  type(C_PTR), value :: p
end function fftwf_estimate_cost
```

Returns

`fftwf_estimate_cost` always returns 0.0.

Parameters

p Input parameter

`p` is `fftwf_plan`

An FFT plan created from a preceding call

5.11.9 fftwf_flops

`fftwf_flops` provides a measure of the number of adds, multiplies and FMAs done during execution of an FFT plan. In Arm Performance Libraries all costs are currently returned as 0.0.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_flops(const fftwf_plan plan, double *add, double *mul, double *fma);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_flops(p,add,mul,fmas) bind(C, name='fftwf_flops')
  type(C_PTR), value :: p
  real(C_DOUBLE), intent(out) :: add
  real(C_DOUBLE), intent(out) :: mul
  real(C_DOUBLE), intent(out) :: fmas
end subroutine fftwf_flops

real(C_DOUBLE) function fftwf_estimate_cost(p) &
    bind(C, name='fftwf_estimate_cost')
  type(C_PTR), value :: p
end function fftwf_estimate_cost
```

Parameters

p Input parameter

`p` is `fftwf_plan`

An FFT plan created from a preceding call

add Input parameter

`add` is a `double*`

`add` is a pointer to a single `double` value into which the number of adds is returned

mul Input parameter

`mul` is a `double*`

`mul` is a pointer to a single `double` value into which the number of multiplies is returned

fma Input parameter

`fma` is a `double*`

`fma` is a pointer to a single `double` value into which the number of FMAs is returned

5.11.10 fftwf_fprint_plan

`fftwf_fprint_plan` is indended to provide a method of printing an FFT plan to a previously opened file. In Arm Performance Libraries this functionality is currently not supported, and a warning message will be printed to STDERR instead.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_fprint_plan(const fftwf_plan plan, FILE *out);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_fprint_plan(p,output_file) &
    bind(C, name='fftwf_fprint_plan')
  type(C_PTR), value :: p
  type(C_PTR), value :: output_file
end subroutine fftwf_fprint_plan
```

Parameters

p Input parameter

p is fftwf_plan

An FFT plan created from a preceding call

out Input parameter

out is FILE *

out is a pointer to a previously opened file.

Constraint: The file pointer output_file must be opened previous to calling fftwf_fprintf_plan.

5.11.11 fftwf_print_plan

fftwf_print_plan is indended to provide a method of printing an FFT plan to STDOUT. In Arm Performance Libraries this functionality is currently not supported, and a warning message will be printed to STDERR instead.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_print_plan(const fftwf_plan p);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_print_plan(p) bind(C, name='fftwf_print_plan')
  type(C_PTR), value :: p
end subroutine fftwf_print_plan
```

Parameters

p Input parameter

p is fftwf_plan

An FFT plan created from a preceding call

5.11.12 fftwf_set_timelimit

fftwf_set_timelimit sets a recommended maximum time that should be used in planning FFT transforms. The Arm Performance Libraries implementation uses this as a guideline, stopping once the allowed time has been exhausted, or if it expects further planning to take it over this limit. The use of planning flags, e.g. FFTW_EXHAUSTIVE and friends, are all truncated at this time limit.

To unset the timelimit pass in FFTW_NO_TIMELIMIT to seconds.

Syntax

C specification:

```
#include "fftw3.h"

void fftwf_set_timelimit(double seconds);
```

Fortran 2003 specification:

```
use, intrinsic :: iso_c_binding
include 'fftw3.f03'

subroutine fftwf_set_timelimit(t) bind(C, name='fftwf_set_timelimit')
  real(C_DOUBLE), value :: t
end subroutine fftwf_set_timelimit
```

Parameters

seconds Input parameter

seconds is a double

seconds is a the maximum number of seconds for which the planning time for subsequent FFT plans will be limited.

Note: Pass in FFTW_NO_TIMELIMIT to unset this limit

5.11.13 fftwh_cost

fftwh_cost provides a measure of the estimated work in executing an FFT plan. In Arm Performance Libraries all costs are currently returned as 0.0.

Syntax

C specification:

```
#include "fftw3.h"

double fftwh_cost(const fftwh_plan p);
```

Returns

`fftwh_cost` always returns 0.0.

Parameters

p Input parameter

`p` is `fftwh_plan`

An FFT plan created from a preceding call

5.11.14 fftwh_estimate_cost

`fftwh_estimate_cost` provides a measure of the estimated work in executing an FFT plan. In Arm Performance Libraries all costs are currently returned as 0.0.

Syntax

C specification:

```
#include "fftw3.h"

double fftwh_estimate_cost(const fftwh_plan p);
```

Returns

`fftwh_estimate_cost` always returns 0.0.

Parameters

p Input parameter

`p` is `fftwh_plan`

An FFT plan created from a preceding call

5.11.15 fftwh_flops

`fftwh_flops` provides a measure of the number of adds, multiplies and FMAs done during execution of an FFT plan. In Arm Performance Libraries all costs are currently returned as 0.0.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_flops(const fftwh_plan plan, double *add, double *mul, double *fma);
```

Parameters

p Input parameter

p is fftwh_plan

An FFT plan created from a preceding call

add Input parameter

add is a double*

add is a pointer to a single double value into which the number of adds is returned

mul Input parameter

mul is a double*

mul is a pointer to a single double value into which the number of multiplies is returned

fma Input parameter

fma is a double*

fma is a pointer to a single double value into which the number of FMAs is returned

5.11.16 fftwh_fprint_plan

fftwh_fprint_plan is indended to provide a method of printing an FFT plan to a previously opened file. In Arm Performance Libraries this functionality is currently not supported, and a warning message will be printed to STDERR instead.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_fprint_plan(const fftwh_plan plan, FILE *out);
```

Parameters

p Input parameter

p is fftwh_plan

An FFT plan created from a preceding call

out Input parameter

out is FILE *

out is a pointer to a previously opened file.

Constraint: The file pointer output_file must be opened previous to calling fftwh_fprintf_plan.

5.11.17 fftwh_print_plan

fftwh_print_plan is indended to provide a method of printing an FFT plan to STDOUT. In Arm Performance Libraries this functionality is currently not supported, and a warning message will be printed to STDERR instead.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_print_plan(const fftwh_plan p);
```

Parameters

p Input parameter

`p` is `fftwh_plan`

An FFT plan created from a preceding call

5.11.18 fftwh_set_timelimit

`fftwh_set_timelimit` sets a recommended maximum time that should be used in planning FFT transforms. The Arm Performance Libraries implementation uses this as a guideline, stopping once the allowed time has been exhausted, or if it expects further planning to take it over this limit. The use of planning flags, e.g. `FFTW_EXHAUSTIVE` and friends, are all truncated at this time limit.

To unset the timelimit pass in `FFTW_NO_TIMELIMIT` to `seconds`.

Syntax

C specification:

```
#include "fftw3.h"

void fftwh_set_timelimit(double seconds);
```

Parameters

seconds Input parameter

`seconds` is a `double`

`seconds` is a the maximum number of seconds for which the planning time for subsequent FFT plans will be limited.

Note: Pass in `FFTW_NO_TIMELIMIT` to unset this limit

CHAPTER

SIX

SPARSE LINEAR ALGEBRA

6.1 Sparse Linear Algebra Introduction

Vendor libraries, like Arm Performance Libraries, aim to provide the highest performing linear algebra solutions, and significant gains in performance are possible over a reference version through using a tuned implementation. Extending this model to sparse linear algebra does give users the option of performance improvements through use of the vendor library implementation. However, unlike for BLAS and LAPACK, there is no standard interface for sparse linear algebra. Instead we have had to adopt our own interface that offers users the opportunity for the largest performance gains, and is not dissimilar to other vendor libraries offerings.

The implementation of sparse linear algebra in Arm Performance Libraries uses an *inspector-executor* model. This allows users to create the sparse matrix structure once and reuse it many times, and is based around providing performance for this very common use-case. There is therefore a performance overhead during the first *optimize* phase, but repeated calls to *execute* will give noticeable benefits in performance.

If the structure is only going to be used once the user can provide a *hint* to the library to minimize the amount of preprocessing done on this data, ensuring that single-shot execution is not slowed down by creating structure that would only give benefits with many executions. Additional hints can be given to help the library make further optimizations including information on the structure (e.g. symmmetric, banded, etc), usage (e.g. transposed) and memory (e.g. whether allocating should be allowed). Note these hints might be used, or ignored, as appropriate during the creation of the internal sparse representation of the matrix.

The basic usage pattern is given by the following sequence for an SpMV use-case:

1. Create sparse matrix object: `armpl_spmat_create_csr_[sdcz]()`
2. Supply hints on usage: `armpl_spmat_hint()`
3. Optimize for SpMV: `armpl_spmv_optimize()`
4. Solve SpMV case: `armpl_spmv_solve_[sdcz]()`
5. Destroy sparse matrix object: `armpl_spmat_destroy()`

In addition users can choose to update a set of non-zero values using `armpl_spmat_update_[sdcz]()`.

Each routine returns an error handle that can be used to interrogate errors during execution.

Note also, at present this interface is only available from the C interface. A Fortran interface will be added in a future release.

6.2 Example of SpMV usage

An example case of using the Arm Performance Libraries sparse interface is given through the following code.

```
/* Double precision sparse matrix-vector multiplication example */
/*
 * ARMPL version 19.2 Copyright Arm 2019
 */
```

(continues on next page)

(continued from previous page)

```
#include <stdio.h>
#include <stdlib.h>
#include "armpl.h"

#define NNZ 12
#define M 5
#define N 5

int main()
{
    /* 1. Set-up local CSR structure */
    armpl_spmat_t armpl_mat;
    const armpl_int_t ntests = 1000;
    const double alpha = 1.0, beta = 0.0;
    armpl_int_t creation_flags = 0;
    double vals[NNZ] = {1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0,
                        11.0, 12.0};
    armpl_int_t row_ptr[M+1] = {0, 2, 4, 7, 9, 12};
    armpl_int_t col_indx[NNZ] = {0, 2, 1, 3, 1, 2, 3, 2, 3, 3, 4};

    /* 2. Set-up Arm Performance Libraries sparse matrix object */
    armpl_status_t info = armpl_spmat_create_csr_d(&armpl_mat, M, N, row_ptr,
                                col_indx, vals, creation_flags);
    if (info!=ARMPL_STATUS_SUCCESS)
          printf("ERROR: armpl_spmat_create_csr_d returned %d\n", info);

    /* 3a. Supply any pertinent information that is known about the matrix */
    info = armpl_spmat_hint(armpl_mat, ARMPL_SPARSE_HINT_STRUCTURE,
                            ARMPL_SPARSE_STRUCTURE_UNSTRUCTURED);
    if (info!=ARMPL_STATUS_SUCCESS)
          printf("ERROR: armpl_spmat_hint returned %d\n", info);

    /* 3b. Supply any hints that are about the SpMV calculations
         to be performed */
    info = armpl_spmat_hint(armpl_mat, ARMPL_SPARSE_HINT_SPMV_OPERATION,
                            ARMPL_SPARSE_OPERATION_NOTRANS);
    if (info!=ARMPL_STATUS_SUCCESS)
          printf("ERROR: armpl_spmat_hint returned %d\n", info);

    info = armpl_spmat_hint(armpl_mat, ARMPL_SPARSE_HINT_SPMV_INVOCATIONS,
                            ARMPL_SPARSE_INVOCATIONS_MANY);
    if (info!=ARMPL_STATUS_SUCCESS)
          printf("ERROR: armpl_spmat_hint returned %d\n", info);

    /* 4. Call an optimization process that will learn from the hints you
        have previously supplied */
    info = armpl_spmv_optimize(armpl_mat);
    if (info!=ARMPL_STATUS_SUCCESS)
          printf("ERROR: armpl_spmv_optimize returned %d\n", info);

    /* 5. Setup input and output vectors and then do SpMV and print result. */
    double *x = (double *)malloc(N*sizeof(double));
    for (int i=0; i<N; i++) {
            x[i] = 1.0;
    }
    double *y = (double *)malloc(M*sizeof(double));

    for (int i=0; i<ntests; i++) {
            info = armpl_spmv_exec_d(ARMPL_SPARSE_OPERATION_NOTRANS, alpha,
                            armpl_mat, x, beta, y);
```

(continues on next page)

(continued from previous page)

```
            if (info!=ARMPL_STATUS_SUCCESS)
            printf("ERROR: armpl_spmv_exec_d returned %d\n", info);
    }

    printf("Computed vector y:\n");
    for (int i=0; i<M; i++) {
            printf("\t%2.1f\n", y[i]);
    }

    /* 6. Destroy created matrix to free any memory created during the
        'optimize' phase */
    info = armpl_spmat_destroy(armpl_mat);
    if (info!=ARMPL_STATUS_SUCCESS)
          printf("ERROR: armpl_spmat_destroy returned %d\n", info);

    /* 7. Free user allocated storage */
    free(x); free(y);

    return (int)info;
}
```

6.3 Sparse Linear Algebra Functions

6.3.1 armpl_spmat_create_coo_c

To create a complex single precision sparse matrix object from input data given in COOrdinate (COO) format, use **armpl_spmat_create_coo_c**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_coo_c(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n, armpl_int_t nnz,
                                        const armpl_int_t *row_indx,
                                        const armpl_int_t *col_indx,
                                        const armpl_singlecomplex_t *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_coo(A, m, n, nnz, row_indx, col_indx, vals, flags,␣
↪info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n, nnz
         integer, intent(in) :: row_indx(*)
         integer, intent(in) :: col_indx(*)
         real(kind=armpl_r64), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_coo
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Output parameter

`A` is `armpl_spmat_t*`

The sparse matrix object to be created.

`m` Input parameter

`m` is `armpl_int_t`

`m` is the number of rows in the sparse matrix.

Constraint: `m` >= 0

`n` Input parameter

`n` is `armpl_int_t`

`n` is the number of columns in the sparse matrix.

Constraint: `n` >= 0

`nnz` Input parameter

`nnz` is `armpl_int_t`

`nnz` is the number of non-zeroes in the sparse matrix.

Constraint: `nnz` >= 0

`row_indx` Input parameter

`row_indx` is `const armpl_int_t*`

`row_indx` is an array listing the rows for each non-zero entry.

Constraints: Array of length `m`.

Although not checked at runtime, `col_indx` are expected to be in the range:

- Using the C/C++ interface: 0 <= `row_indx[i]` <= `n-1`.
- Using the Fortran interface: 1 <= `row_indx[i]` <= `n`.

`col_indx` Input parameter

`col_indx` is `const armpl_int_t*`

`col_indx` is an array listing the columns for each non-zero entry.

Constraints: Array of length `n`.

Although not checked at runtime, `col_indx` are expected to be in the range:

- Using the C/C++ interface: 0 <= `col_indx[i]` <= `n-1`.
- Using the Fortran interface: 1 <= `col_indx[i]` <= `n`.

vals Input parameter

`vals` is `const armpl_singlecomplex_t*`

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length `nnz`

flags Input parameter

`flags` is `armpl_int_t`

Use this flag to create certain properties of the matrix. It can be set to:

- `0`. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- `ARMPL_SPARSE_CREATE_NOCOPY`. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to `armpl_spmat_destroy` with the `armpl_spmat` object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to `armpl_spmv_optimize`.

6.3.2 armpl_spmat_create_coo_d

To create a real double precision sparse matrix object from input data given in COOrdinate (COO) format, use **armpl_spmat_create_coo_d**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_coo_d(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n, armpl_int_t nnz,
                                        const armpl_int_t *row_indx,
                                        const armpl_int_t *col_indx,
                                        const double *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_coo(A, m, n, nnz, row_indx, col_indx, vals, flags,␣
↪info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n, nnz
         integer, intent(in) :: row_indx(*)
         integer, intent(in) :: col_indx(*)
         complex(kind=armpl_r32), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_coo
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **ARMPL_STATUS_SUCCESS** The function returned with no errors.
- **ARMPL_STATUS_INPUT_PARAMETER_ERROR** An error was found with the supplied input parameters.
- **ARMPL_STATUS_EXECUTION_FAILURE** The function failed for an alternative reason.

Parameters

A Output parameter

A is armpl_spmat_t*

The sparse matrix object to be created.

m Input parameter

m is armpl_int_t

m is the number of rows in the sparse matrix.

Constraint: m >= 0

n Input parameter

n is armpl_int_t

n is the number of columns in the sparse matrix.

Constraint: n >= 0

nnz Input parameter

nnz is armpl_int_t

nnz is the number of non-zeroes in the sparse matrix.

Constraint: nnz >= 0

row_indx Input parameter

row_indx is const armpl_int_t*

row_indx is an array listing the rows for each non-zero entry.

Constraints: Array of length m.

Although not checked at runtime, row_indx are expected to be in the range:

- Using the C/C++ interface: 0 <= row_indx[i] <= n-1.
- Using the Fortran interface: 1 <= row_indx[i] <= n.

col_indx Input parameter

col_indx is const armpl_int_t*

col_indx is an array listing the columns for each non-zero entry.

Constraints: Array of length n

Although not checked at runtime, col_indx are expected to be in the range:

- Using the C/C++ interface: 0 <= col_indx[i] <= n-1.
- Using the Fortran interface: 1 <= col_indx[i] <= n.

vals Input parameter

vals is const double*

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length nnz

flags Input parameter

`flags` is `armpl_int_t`

Use this flag to create certain properties of the matrix. This can be set to:

- `0`. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- `ARMPL_SPARSE_CREATE_NOCOPY`. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to `armpl_spmat_destroy` with the `armpl_spmat` object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to `armpl_spmv_optimize`.

6.3.3 armpl_spmat_create_coo_s

To create a real single precision sparse matrix object from input data given in COOrdinate (COO) format, use **armpl_spmat_create_coo_s**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_coo_s(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n, armpl_int_t nnz,
                                        const armpl_int_t *row_indx,
                                        const armpl_int_t *col_indx,
                                        const float *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_coo(A, m, n, nnz, row_indx, col_indx, vals, flags,␣
↪info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n, nnz
         integer, intent(in) :: row_indx(*)
         integer, intent(in) :: col_indx(*)
         real(kind=armpl_r32), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_coo
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **ARMPL_STATUS_SUCCESS** The function returned with no errors.
- **ARMPL_STATUS_INPUT_PARAMETER_ERROR** An error was found with the supplied input parameters.
- **ARMPL_STATUS_EXECUTION_FAILURE** The function failed for an alternative reason.

Parameters

A Output parameter

A is `armpl_spmat_t*`

The sparse matrix object to be created.

m Input parameter

m is `armpl_int_t`

m is the number of rows in the sparse matrix.

Constraint: m >= 0

n Input parameter

n is `armpl_int_t`

n is the number of columns in the sparse matrix.

Constraint: n >= 0

nnz Input parameter

nnz is `armpl_int_t`

nnz is the number of non-zeroes in the sparse matrix.

Constraint: nnz >= 0

row_indx Input parameter

row_indx is `const armpl_int_t*`

row_indx is an array listing the rows for each non-zero entry.

Constraints: Array of length m.

Although not checked at runtime, row_indx are expected to be in the range:

- Using the C/C++ interface: 0 <= `row_indx[i]` <= `n-1`.
- Using the Fortran interface: 1 <= `row_indx[i]` <= n.

col_indx Input parameter

col_indx is `const armpl_int_t*`

col_indx is an array listing the columns for each non-zero entry.

Constraints: Array of length n.

Although not checked at runtime, col_indx are expected to be in the range:

- Using the C/C++ interface: 0 <= `col_indx[i]` <= `n-1`.
- Using the Fortran interface: 1 <= `col_indx[i]` <= n.

vals Input parameter

vals is `const float*`

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length nnz

flags Input parameter

flags is `armpl_int_t`

Use this flag to create certain properties of the matrix. This can be set to:

- 0. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.

- `ARMPL_SPARSE_CREATE_NOCOPY`. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to `armpl_spmat_destroy` with the `armpl_spmat` object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to `armpl_spmv_optimize`.

6.3.4 armpl_spmat_create_coo_z

To create a complex double precision sparse matrix object from input data given in COOrdinate (COO) format, use **armpl_spmat_create_coo_z**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_coo_z(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n, armpl_int_t nnz,
                                        const armpl_int_t *row_indx,
                                        const armpl_int_t *col_indx,
                                        const armpl_doublecomplex_t *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_coo(A, m, n, nnz, row_indx, col_indx, vals, flags,␣
↪info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n, nnz
         integer, intent(in) :: row_indx(*)
         integer, intent(in) :: col_indx(*)
         complex(kind=armpl_r64), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_coo
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Output parameter

`A` is `armpl_spmat_t*`

The sparse matrix object to be created.

m Input parameter

m is armpl_int_t

m is the number of rows in the sparse matrix.

Constraint: m >= 0

n Input parameter

n is armpl_int_t

n is the number of columns in the sparse matrix.

Constraint: n >= 0

nnz Input parameter

nnz is armpl_int_t

nnz is the number of non-zeroes in the sparse matrix.

Constraint: nnz >= 0

row_indx Input parameter

row_indx is const armpl_int_t*

row_indx is an array listing the rows for each non-zero entry.

Constraints: Array of length m.

Although not checked at runtime, row_indx are expected to be in the range:

- Using the C/C++ interface: 0 <= row_indx[i] <= n-1.
- Using the Fortran interface: 1 <= row_indx[i] <= n.

col_indx Input parameter

col_indx is const armpl_int_t*

col_indx is an array listing the columns for each non-zero entry.

Constraints: Array of length n.

Although not checked at runtime, col_indx are expected to be in the range:

- Using the C/C++ interface: 0 <= col_indx[i] <= n-1.
- Using the Fortran interface: 1 <= col_indx[i] <= n.

vals Input parameter

vals is const armpl_doublecomplex_t*

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length nnz

flags Input parameter

flags is armpl_int_t

Use this flag to create certain properties of the matrix. This can be set to:

- 0. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- ARMPL_SPARSE_CREATE_NOCOPY. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to armpl_spmat_destroy with the armpl_spmat object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to armpl_spmv_optimize.

6.3.5 armpl_spmat_create_csc_c

To create a complex single precision sparse matrix object from input data given in Compressed Sparse Column (CSC) format, use **armpl_spmat_create_csc_c**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_csc_c(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n,
                                        const armpl_int_t *row_indx,
                                        const armpl_int_t *col_ptr,
                                        const armpl_singlecomplex_t *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_csc(A, m, n, row_indx, col_ptr, vals, flags, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n
         integer, intent(in) :: row_indx(*)
         integer, intent(in) :: col_ptr(n+1)
         complex(kind=armpl_r32), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_csc
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Output parameter

`A` is `armpl_spmat_t*`

The sparse matrix object to be created.

`m` Input parameter

`m` is `armpl_int_t`

`m` is the number of rows in the sparse matrix.

Constraint: `m` >= 0

n Input parameter

n is armpl_int_t

n is the number of columns in the sparse matrix.

Constraint: n >= 0

row_indx Input parameter

row_indx is const armpl_int_t*

row_indx is an array listing the rows for each non-zero entry.

Constraints: Array of length NNZ = col_ptr[M] - col_ptr[0] (where col_ptr[0] denotes the index offset)

Although not checked at runtime, row_indx are expected to be in the range:

- 0 <= row_indx[i] <= n-1 when ‘‘col_ptr[0]‘‘=0.
- 1 <= row_indx[i] <= n when ‘‘col_ptr[0]‘‘=1.

col_ptr Input parameter

col_ptr is const armpl_int_t*

col_ptr is an array that provides the index into row_indx and vals for each column of the sparse matrix A. i.e. row_indx[col_ptr[i]] is the first non-zero row index present in column i.

Constraints: Array of length n+1

col_ptr[0] must be 0 or 1 denoting array indexing from 0 (C) or 1 (Fortran).

col_ptr[n] will be the (total number of non-zeroes)+‘‘col_ptr[0]‘‘.

vals Input parameter

vals is const armpl_singlecomplex_t*

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length NNZ

flags Input parameter

flags is armpl_int_t

Use this flag to create certain properties of the matrix. This can be set to:

- 0. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- ARMPL_SPARSE_CREATE_NOCOPY. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to armpl_spmat_destroy with the armpl_spmat object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to armpl_spmv_optimize.

6.3.6 armpl_spmat_create_csc_d

To create a real double precision sparse matrix object from input data given in Compressed Sparse Column (CSC) format, use **armpl_spmat_create_csc_d**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_csc_d(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n,
                                        const armpl_int_t *row_indx,
                                        const armpl_int_t *col_ptr,
                                        const double *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_csc(A, m, n, row_indx, col_ptr, vals, flags, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n
         integer, intent(in) :: row_indx(*)
         integer, intent(in) :: col_ptr(n+1)
         real(kind=armpl_r64), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_csc
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Output parameter

`A` is `armpl_spmat_t*`

The sparse matrix object to be created.

`m` Input parameter

`m` is `armpl_int_t`

`m` is the number of rows in the sparse matrix.

Constraint: `m` >= 0

`n` Input parameter

`n` is `armpl_int_t`

`n` is the number of columns in the sparse matrix.

Constraint: `n` >= 0

`row_indx` Input parameter

`row_indx` is `const armpl_int_t*`

`row_indx` is an array listing the rows for each non-zero entry.

Constraints: Array of length NNZ = `col_ptr[M] - col_ptr[0]` (where `col_ptr[0]` denotes the index offset).

Although not checked at runtime, `row_indx` are expected to be in the range:

- 0 <= `row_indx[i]` <= `n-1` when ‘‘col_ptr[0]‘‘=0.
- 1 <= `row_indx[i]` <= `n` when ‘‘col_ptr[0]‘‘=1.

`col_ptr` Input parameter

`col_ptr` is `const armpl_int_t*`

`col_ptr` is an array that provides the index into `row_indx` and `vals` for each column of the sparse matrix A. i.e. `row_indx[col_ptr[i]]` is the first non-zero row index present in column `i`.

Constraints: Array of length `n+1`

`col_ptr[0]` must be 0 or 1 denoting array indexing from 0 (C) or 1 (Fortran).

`col_ptr[n]` will be the (total number of non-zeroes)+‘‘col_ptr[0]‘‘.

`vals` Input parameter

`vals` is `const double*`

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length NNZ

`flags` Input parameter

`flags` is `armpl_int_t`

Use this flag to create certain properties of the matrix. This can be set to:

- `0`. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- `ARMPL_SPARSE_CREATE_NOCOPY`. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to `armpl_spmat_destroy` with the `armpl_spmat` object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to `armpl_spmv_optimize`.

6.3.7 armpl_spmat_create_csc_s

To create a real single precision sparse matrix object from input data given in Compressed Sparse Column (CSC) format, use **armpl_spmat_create_csc_s**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_csc_s(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n,
                                        const armpl_int_t *row_indx,
                                        const armpl_int_t *col_ptr,
                                        const float *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_csc(A, m, n, row_indx, col_ptr, vals, flags, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n
         integer, intent(in) :: row_indx(*)
         integer, intent(in) :: col_ptr(n+1)
         real(kind=armpl_r32), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_csc
```

Returns

In C/C++ this function returns an `armpl_status_t` which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Output parameter

`A` is `armpl_spmat_t*`

The sparse matrix object to be created.

`m` Input parameter

`m` is `armpl_int_t`

`m` is the number of rows in the sparse matrix.

Constraint: `m` >= 0

`n` Input parameter

`n` is `armpl_int_t`

`n` is the number of columns in the sparse matrix.

Constraint: `n` >= 0

`row_indx` Input parameter

`row_indx` is `const armpl_int_t*`

`row_indx` is an array listing the rows for each non-zero entry.

Constraints: Array of length NNZ = `col_ptr[M] - col_ptr[0]` (where `col_ptr[0]` denotes the index offset)

Although not checked at runtime, `row_indx` are expected to be in the range:

- 0 <= `row_indx[i]` <= `n-1` when ‘‘col_ptr[0]‘‘=0.
- 1 <= `row_indx[i]` <= `n` when ‘‘col_ptr[0]‘‘=1.

col_ptr Input parameter

col_ptr is const armpl_int_t*

col_ptr is an array that provides the index into row_indx and vals for each column of the sparse matrix A. i.e. row_indx[col_ptr[i]] is the first non-zero row index present in column i.

Constraints: Array of length n+1

col_ptr[0] must be 0 or 1 denoting array indexing from 0 (C) or 1 (Fortran).

col_ptr[n] will be the (total number of non-zeroes)+‘‘col_ptr[0]‘‘.

vals Input parameter

vals is const float*

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length NNZ

flags Input parameter

flags is armpl_int_t

Use this flag to create certain properties of the matrix. This can be set to:

- 0. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- ARMPL_SPARSE_CREATE_NOCOPY. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to armpl_spmat_destroy with the armpl_spmat object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to armpl_spmv_optimize.

6.3.8 armpl_spmat_create_csc_z

To create a complex double precision sparse matrix object from input data given in Compressed Sparse Column (CSC) format, use **armpl_spmat_create_csc_z**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_csc_z(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n,
                                        const armpl_int_t *row_indx,
                                        const armpl_int_t *col_ptr,
                                        const armpl_doublecomplex_t *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_csc(A, m, n, row_indx, col_ptr, vals, flags, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n
         integer, intent(in) :: row_indx(*)
         integer, intent(in) :: col_ptr(n+1)
         complex(kind=armpl_r64), intent(in) :: vals(*)
         integer, intent(in) :: flags
```

(continues on next page)

(continued from previous page)

```
        integer, intent(out) :: info
end subroutine armpl_spmat_create_csc
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Output parameter

`A` is `armpl_spmat_t*`

The sparse matrix object to be created.

`m` Input parameter

`m` is `armpl_int_t`

`m` is the number of rows in the sparse matrix.

Constraint: `m` >= 0

`n` Input parameter

`n` is `armpl_int_t`

`n` is the number of columns in the sparse matrix.

Constraint: `n` >= 0

`row_indx` Input parameter

`row_indx` is `const armpl_int_t*`

`row_indx` is an array listing the rows for each non-zero entry.

Constraints: Array of length NNZ = `col_ptr[M] - col_ptr[0]` (where `col_ptr[0]` denotes the index offset).

Although not checked at runtime, `row_indx` are expected to be in the range:

- 0 <= `row_indx[i]` <= `n-1` when ‘‘col_ptr[0]‘‘=0.
- 1 <= `row_indx[i]` <= `n` when ‘‘col_ptr[0]‘‘=1.

`col_ptr` Input parameter

`col_ptr` is `const armpl_int_t*`

`col_ptr` is an array that provides the index into `row_indx` and `vals` for each column of the sparse matrix A. i.e. `row_indx[col_ptr[i]]` is the first non-zero row index present in column `i`.

Constraints: Array of length `n+1`

`col_ptr[0]` must be 0 or 1 denoting array indexing from 0 (C) or 1 (Fortran).

`col_ptr[n]` will be the (total number of non-zeroes)+‘‘col_ptr[0]‘‘.

vals Input parameter

vals is const armpl_doublecomplex_t*

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length NNZ.

flags Input parameter

flags is armpl_int_t

Use this flag to create certain properties of the matrix. This can be set to:

- 0. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- ARMPL_SPARSE_CREATE_NOCOPY. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to armpl_spmat_destroy with the armpl_spmat object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to armpl_spmv_optimize.

6.3.9 armpl_spmat_create_csr_c

To create a complex single precision sparse matrix object from input data given in Compressed Sparse Row (CSR) format, use **armpl_spmat_create_csr_c**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_csr_c(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n,
                                        const armpl_int_t *row_ptr,
                                        const armpl_int_t *col_indx,
                                        const armpl_singlecomplex_t *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_csr(A, m, n, row_ptr, col_indx, vals, flags, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n
         integer, intent(in) :: row_ptr(m+1)
         integer, intent(in) :: col_indx(*)
         complex(kind=armpl_r32), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_csr
```

Returns

In C/C++, this function returns an armpl_status_t, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter info.

Possible return values are:

- **ARMPL_STATUS_SUCCESS** The function returned with no errors.
- **ARMPL_STATUS_INPUT_PARAMETER_ERROR** An error was found with the supplied input parameters.
- **ARMPL_STATUS_EXECUTION_FAILURE** The function failed for an alternative reason.

Parameters

A Output parameter

A is armpl_spmat_t*

The sparse matrix object to be created.

m Input parameter

m is armpl_int_t

m is the number of rows in the sparse matrix.

Constraint: m >= 0

n Input parameter

n is armpl_int_t

n is the number of columns in the sparse matrix.

Constraint: n >= 0

row_ptr Input parameter

row_ptr is const armpl_int_t*

row_ptr is an array that provides the index into col_indx and vals for each row of the sparse matrix A. i.e. col_indx[row_ptr[i]] is the first non-zero column index present in row i.

Constraint: Array of length m+1

row_ptr[0] must be 0 or 1 denoting array indexing from 0 (C) or 1 (Fortran).

row_ptr[m] will be the (total number of non-zeroes)+‘‘row_ptr[0]‘‘

col_indx Input parameter

col_indx is const armpl_int_t*

col_indx is an array listing the columns for each non-zero entry.

Constraints Array of length NNZ = row_ptr[M] - row_ptr[0] (where row_ptr[0] denotes the index offset).

Although not checked at runtime, col_indx are expected to be in the range:

- 0 <= row_indx[i] <= n-1 when ‘‘col_ptr[0]‘‘=0.
- 1 <= row_indx[i] <= n when ‘‘col_ptr[0]‘‘=1.

vals Input parameter

vals is const armpl_singlecomplex_t*

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length NNZ.

flags

Input parameter

flags is armpl_int_t

Use this flag to create certain properties of the matrix. This can be set to:

- `0`. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- `ARMPL_SPARSE_CREATE_NOCOPY`. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to `armpl_spmat_destroy` with the `armpl_spmat` object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to `armpl_spmv_optimize`.

6.3.10 armpl_spmat_create_csr_d

To create a real double precision sparse matrix object from input data given in Compressed Sparse Row (CSR) format, **armpl_spmat_create_csr_d**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_csr_d(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n,
                                        const armpl_int_t *row_ptr,
                                        const armpl_int_t *col_indx,
                                        const double *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_csr(A, m, n, row_ptr, col_indx, vals, flags, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n
         integer, intent(in) :: row_ptr(m+1)
         integer, intent(in) :: col_indx(*)
         real(kind=armpl_r64), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_csr
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Output parameter

`A` is `armpl_spmat_t*`

The sparse matrix object to be created.

m Input parameter

m is armpl_int_t

m is the number of rows in the sparse matrix.

Constraint: m >= 0

n Input parameter

n is armpl_int_t

n is the number of columns in the sparse matrix.

Constraint: n >= 0

row_ptr Input parameter

row_ptr is const armpl_int_t*

row_ptr is an array that provides the index into col_indx and vals for each row of the sparse matrix A. i.e. col_indx[row_ptr[i]] is the first non-zero column index present in row i.

Constraints: Array of length m+1

row_ptr[0] must be 0 or 1 denoting array indexing from 0 (C) or 1 (Fortran).

row_ptr[m] will be the (total number of non-zeroes)+‘‘row_ptr[0]‘‘.

col_indx Input parameter

col_indx is const armpl_int_t*

col_indx is an array listing the columns for each non-zero entry.

Constraints Array of length NNZ = row_ptr[M] - row_ptr[0] (where row_ptr[0] denotes the index offset).

Although not checked at runtime, col_indx are expected to be in the range:

- 0 <= row_indx[i] <= n-1 when ‘‘col_ptr[0]‘‘=0.
- 1 <= row_indx[i] <= n when ‘‘col_ptr[0]‘‘=1.

vals Input parameter

vals is const double*

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length NNZ

flags Input parameter

flags is armpl_int_t

Use this flag to create certain properties of the matrix. This can be set to:

- 0. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- ARMPL_SPARSE_CREATE_NOCOPY. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to armpl_spmat_destroy with the armpl_spmat object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to armpl_spmv_optimize.

6.3.11 armpl_spmat_create_csr_s

To create a real single precision sparse matrix object from input data given in Compressed Sparse Row (CSR) format, use **armpl_spmat_create_csr_s**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_csr_s(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n,
                                        const armpl_int_t *row_ptr,
                                        const armpl_int_t *col_indx,
                                        const float *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_csr(A, m, n, row_ptr, col_indx, vals, flags, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n
         integer, intent(in) :: row_ptr(m+1)
         integer, intent(in) :: col_indx(*)
         real(kind=armpl_r32), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_csr
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Output parameter

`A` is `armpl_spmat_t*`

The sparse matrix object to be created.

`m` Input parameter

`m` is `armpl_int_t`

`m` is the number of rows in the sparse matrix.

Constraint: `m` >= 0

`n` Input parameter

`n` is `armpl_int_t`

`n` is the number of columns in the sparse matrix.

Constraint: `n` >= 0

row_ptr Input parameter

row_ptr is const armpl_int_t*

row_ptr is an array that provides the index into col_indx and vals for each row of the sparse matrix A. i.e. col_indx[row_ptr[i]] is the first non-zero column index present in row i.

Constraint: Array of length m+1

row_ptr[0] must be 0 or 1 denoting array indexing from 0 (C) or 1 (Fortran).

row_ptr[m] will be the (total number of non-zeroes)+‘‘row_ptr[0]‘‘.

col_indx Input parameter

col_indx is const armpl_int_t*

col_indx is an array listing the columns for each non-zero entry.

Constraints Array of length NNZ = row_ptr[M] - row_ptr[0] (where row_ptr[0] denotes the index offset).

Although not checked at runtime, col_indx are expected to be in the range:

- 0 <= row_indx[i] <= n-1 when ‘‘col_ptr[0]‘‘=0.
- 1 <= row_indx[i] <= n when ‘‘col_ptr[0]‘‘=1.

vals Input parameter

vals is const float*

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length NNZ.

flags Input parameter

flags is armpl_int_t

Use this flag to create certain properties of the matrix. This can be set to:

- 0. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- ARMPL_SPARSE_CREATE_NOCOPY. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to armpl_spmat_destroy with the armpl_spmat object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to armpl_spmv_optimize.

6.3.12 armpl_spmat_create_csr_z

To create a complex double precision sparse matrix object from input data given in Compressed Sparse Row (CSR) format, use **armpl_spmat_create_csr_z**.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_create_csr_z(armpl_spmat_t *A, armpl_int_t m,
                                        armpl_int_t n,
                                        const armpl_int_t *row_ptr,
                                        const armpl_int_t *col_indx,
                                        const armpl_doublecomplex_t *vals,
                                        armpl_int_t flags);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_create_csr(A, m, n, row_ptr, col_indx, vals, flags, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(out) :: A
         integer, intent(in) :: m, n
         integer, intent(in) :: row_ptr(m+1)
         integer, intent(in) :: col_indx(*)
         complex(kind=armpl_r64), intent(in) :: vals(*)
         integer, intent(in) :: flags
         integer, intent(out) :: info
end subroutine armpl_spmat_create_csr
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Output parameter

`A` is `armpl_spmat_t*`

The sparse matrix object to be created.

`m` Input parameter

`m` is `armpl_int_t`

`m` is the number of rows in the sparse matrix.

Constraint: `m` >= 0

`n` Input parameter

`n` is `armpl_int_t`

`n` is the number of columns in the sparse matrix.

Constraint: `n` >= 0

`row_ptr` Input parameter

`row_ptr` is `const armpl_int_t*`

`row_ptr` is an array that provides the index into `col_indx` and `vals` for each row of the sparse matrix A. i.e. `col_indx[row_ptr[i]]` is the first non-zero column index present in row `i`.

Constraint: Array of length `m+1`

`row_ptr[0]` must be 0 or 1 denoting array indexing from 0 (C) or 1 (Fortran).

`row_ptr[m]` will be the (total number of non-zeroes)+‘‘row_ptr[0]‘‘.

col_indx Input parameter

col_indx is const armpl_int_t*

col_indx is an array listing the columns for each non-zero entry.

Constraints Array of length NNZ = row_ptr[M] - row_ptr[0] (where row_ptr[0] denotes the index offset).

Although not checked at runtime, col_indx are expected to be in the range:

- 0 <= row_indx[i] <= n-1 when ‘‘col_ptr[0]‘‘=0.
- 1 <= row_indx[i] <= n when ‘‘col_ptr[0]‘‘=1.

vals Input parameter

vals is const armpl_doublecomplex_t*

Non-zero entries in the matrix to be represented in the sparse matrix structure.

Constraint: Array of length NNZ

flags Input parameter

flags is armpl_int_t

Use this flag to create certain properties of the matrix. This can be set to:

- 0. No restrictions apply. The function will make a copy of the input arrays, which can be deallocated by the user on return from this function in order to minimize memory usage.
- ARMPL_SPARSE_CREATE_NOCOPY. The function will not make a copy of the input arrays. These input arrays, therefore, **must not** be deallocated until after a call to armpl_spmat_destroy with the armpl_spmat object returned by this function. This will reduce the scope of optimizations that might be applied in subsequent calls to armpl_spmv_optimize.

6.3.13 armpl_spmat_update_c

armpl_spmat_update_c is a utility function to update the values of a previously created sparse matrix object.

The number of entries to be updated is specified such that:

```
For i = 0, n_updates-1

     I = row_index[i]

     J = col_indx[i]

     a_(I,J) = vals[i]
```

Note that this routine cannot change the sparsity pattern, only update the values. A new armpl_spmat_t object should be created if a different structure is needed.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_update_c(armpl_spmat_t A, armpl_int_t n_updates,
                                    const armpl_int_t *row_indx,
                                    const armpl_int_t *col_indx,
                                    const armpl_singlecomplex_t *vals);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_update(A, n_updates, row_indx, col_indx, vals, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(in) :: A
         integer, intent(in) :: n_updates
         integer, intent(in) :: row_indx(n_updates)
         integer, intent(in) :: col_indx(n_updates)
         complex(kind=armpl_r32), intent(in) :: vals(n_updates)
         integer, intent(out) :: info
end subroutine armpl_spmat_update
```

Returns

In C/C++ this function returns an `armpl_status_t` which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Input and output parameter

`A` is `armpl_spmat`

`A` is a sparse matrix structure.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*()` function.

`n_updates` Input parameter

`n_updates` is `armpl_int_t`

`n_updates` gives the number of values to be updated. It is therefore the length of the arrays `row_indx`, `col_indx` and `vals`.

Constraint: `n_updates >= 0`. `ARMPL_STATUS_SUCCESS` is returned if `n_updates=0`.

`row_indx` Input parameter

`row_indx` is `const armpl_int_t*`

`row_indx` is a pointer to an array containing the row indices of the values to be updated.

Constraint: The length of the array is `n_updates`.

`col_indx` Input parameter

`col_indx` is `const armpl_int_t*`

`col_indx` is a pointer to an array containing the column indices of the values to be updated.

Constraint: The length of the array is `n_updates`.

`vals` Input parameter

`vals` is `const armpl_singlecomplex_t*`

`vals` is a pointer to an array with the new non-zero entries to be entered.

Constraint: The length of the array is `n_updates`.

6.3.14 armpl_spmat_update_d

armpl_spmat_update_d is a utility function to update the values of a previously created sparse matrix object.

The number of entries to be updated is specified such that:

```
For i = 0, n_updates-1

     I = row_index[i]

     J = col_indx[i]

     a_(I,J) = vals[i]
```

Note: This routine cannot change the sparsity pattern, only update the values. A new `armpl_spmat_t` object should be created if a different structure is needed.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_update_d(armpl_spmat_t A, armpl_int_t n_updates,
                                    const armpl_int_t *row_indx,
                                    const armpl_int_t *col_indx,
                                    const double *vals);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_update(A, n_updates, row_indx, col_indx, vals, info)
         use armpl_kinds
         implicit none
         integer(kind=armpl_i8), intent(in) :: A
         integer, intent(in) :: n_updates
         integer, intent(in) :: row_indx(n_updates)
         integer, intent(in) :: col_indx(n_updates)
         real(kind=armpl_r64), intent(in) :: vals(n_updates)
         integer, intent(out) :: info
end subroutine armpl_spmat_update
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **ARMPL_STATUS_SUCCESS** The function returned with no errors.
- **ARMPL_STATUS_INPUT_PARAMETER_ERROR** An error was found with the supplied input parameters.
- **ARMPL_STATUS_EXECUTION_FAILURE** The function failed for an alternative reason.

Parameters

A Input and output parameter

A is `armpl_spmat`

A is a sparse matrix structure.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*()` function.

n_updates Input parameter

`n_updates` is `armpl_int_t`

`n_updates` gives the number of values to be updated. It is therefore the length of the arrays `row_indx`, `col_indx` and `vals`.

Constraint: `n_updates >= 0`. `ARMPL_STATUS_SUCCESS` is returned if `n_updates=0`.

row_indx Input parameter

`row_indx` is `const armpl_int_t*`

`row_indx` is a pointer to an array containing the row indices of the values to be updated.

Constraint: The length of the array is `n_updates`.

col_indx Input parameter

`col_indx` is `const armpl_int_t*`

`col_indx` is a pointer to an array containing the column indices of the values to be updated.

Constraint: The length of the array is `n_updates`.

vals Input parameter

`vals` is `const double*`

`vals` is a pointer to an array with the new non-zero entries to be entered.

Constraint: The length of the array is `n_updates`.

6.3.15 armpl_spmat_update_s

armpl_spmat_update_s is a utility function to update the values of a previously created sparse matrix object.

The number of entries to be updated is specified such that:

```
For i = 0, n_updates-1

     I = row_index[i]

     J = col_indx[i]

     a_(I,J) = vals[i]
```

Note: This routine cannot change the sparsity pattern, only update the values. A new `armpl_spmat_t` object should be created if a different structure is needed.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_update_s(armpl_spmat_t A, armpl_int_t n_updates,
                                    const armpl_int_t *row_indx,
                                    const armpl_int_t *col_indx,
                                    const float *vals);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_update(A, n_updates, row_indx, col_indx, vals, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(in) :: A
         integer, intent(in) :: n_updates
         integer, intent(in) :: row_indx(n_updates)
         integer, intent(in) :: col_indx(n_updates)
         real(kind=armpl_r32), intent(in) :: vals(n_updates)
         integer, intent(out) :: info
end subroutine armpl_spmat_update
```

Returns

In C/C++ this function returns an `armpl_status_t` which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Input and output parameter

`A` is `armpl_spmat`

`A` is a sparse matrix structure.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*()` function.

`n_updates` Input parameter

`n_updates` is `armpl_int_t`

`n_updates` gives the number of values to be updated. It is therefore the length of the arrays `row_indx`, `col_indx` and `vals`.

Constraint: `n_updates >= 0`. `ARMPL_STATUS_SUCCESS` is returned if `n_updates=0`.

`row_indx` Input parameter

`row_indx` is `const armpl_int_t*`

`row_indx` is a pointer to an array containing the row indices of the values to be updated.

Constraint: The length of the array is `n_updates`.

`col_indx` Input parameter

`col_indx` is `const armpl_int_t*`

`col_indx` is a pointer to an array containing the column indices of the values to be updated.

Constraint: The length of the array is `n_updates`.

`vals` Input parameter

`vals` is `const float*`

`vals` is a pointer to an array with the new non-zero entries to be entered.

Constraint: The length of the array is `n_updates`.

6.3.16 armpl_spmat_update_z

armpl_spmat_update_z is a utility function to update the values of a previously created sparse matrix object.

The number of entries to be updated is specified such that:

```
For i = 0, n_updates-1

     I = row_index[i]

     J = col_indx[i]

     a_(I,J) = vals[i]
```

Note: This routine cannot change the sparsity pattern, only update the values. A new `armpl_spmat_t` object should be created if a different structure is needed.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_update_z(armpl_spmat_t A, armpl_int_t n_updates,
                                    const armpl_int_t *row_indx,
                                    const armpl_int_t *col_indx,
                                    const armpl_doublecomplex_t *vals);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_update(A, n_updates, row_indx, col_indx, vals, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(in) :: A
         integer, intent(in) :: n_updates
         integer, intent(in) :: row_indx(n_updates)
         integer, intent(in) :: col_indx(n_updates)
         complex(kind=armpl_r64), intent(in) :: vals(n_updates)
         integer, intent(out) :: info
end subroutine armpl_spmat_update
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **ARMPL_STATUS_SUCCESS** The function returned with no errors.
- **ARMPL_STATUS_INPUT_PARAMETER_ERROR** An error was found with the supplied input parameters.
- **ARMPL_STATUS_EXECUTION_FAILURE** The function failed for an alternative reason.

Parameters

A Input and output parameter

A is armpl_spmat

A is a sparse matrix structure.

Constraint: The sparse matrix A should have been previously created using an appropriate armpl_spmat_create_*() function.

n_updates Input parameter

n_updates is armpl_int_t

n_updates gives the number of values to be updated. It is therefore the length of the arrays row_indx, col_indx and vals.

Constraint: n_updates >= 0. ARMPL_STATUS_SUCCESS is returned if n_updates=0.

row_indx Input parameter

row_indx is const armpl_int_t*

row_indx is a pointer to an array containing the row indices of the values to be updated.

Constraint: The length of the array is n_updates.

col_indx Input parameter

col_indx is const armpl_int_t*

col_indx is a pointer to an array containing the column indices of the values to be updated.

Constraint: The length of the array is n_updates.

vals Input parameter

vals is const armpl_doublecomplex_t*

vals is a pointer to an array with the new non-zero entries to be entered.

Constraint: The length of the array is n_updates.

6.3.17 armpl_spmat_hint

armpl_spmat_hint is a utility function to provide various hints that can be used during the optimization phase to allow the library to choose the best implementation.

Multiple hints can be given in separate calls, building extra information into the sparse matrix object each time.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_hint(armpl_spmat_t A, enum sparse_hint_type hint, enum␣
↪sparse_hint_value value);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmat_hint(A, sparse_hint_type, sparse_hint_value, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(in) :: A
         integer(kind=armpl_i4), intent(in) :: sparse_hint_type, sparse_hint_value
         integer, intent(out) :: info
end subroutine armpl_spmat_hint
```

Returns

In C/C++ this function returns an `armpl_status_t` which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Input and output parameter

`A` is `armpl_spmat`

`A` is a sparse matrix structure.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*()` function

`hint` Input parameter

`hint` is `enum sparse_hint_type`

`hint` denotes the type of hint to be supplied.

Constraint: The `hint` should be either `ARMPL_SPARSE_HINT_STRUCTURE`, `ARMPL_SPARSE_HINT_SPMV_OPERATION`, `ARMPL_SPARSE_HINT_MEMORY`, `ARMPL_SPARSE_HINT_SPMV_INVOCATIONS`

`value` Input parameter

`value` is `enum sparse_hint_value`

`value` is the setting for the hint of type `hint`.

Constraint: The hints given should match the values shown in the table below.

Hint structure

Listed below are the various hints that are available for each `ARMPL_SPARSE_HINT_TYPE` option, where (*) indicates the default option for each type:

- `ARMPL_SPARSE_HINT_TYPE``==``ARMPL_SPARSE_HINT_MEMORY`

  `ARMPL_SPARSE_MEMORY_NOALLOCS`

  `ARMPL_SPARSE_MEMORY_ALLOCS` (*)

- `ARMPL_SPARSE_HINT_TYPE``==``ARMPL_SPARSE_HINT_STRUCTURE`

ARMPL_SPARSE_STRUCTURE_DENSE

ARMPL_SPARSE_STRUCTURE_UNSTRUCTURED (*)

ARMPL_SPARSE_STRUCTURE_SYMMETRIC

ARMPL_SPARSE_STRUCTURE_DIAGONAL

ARMPL_SPARSE_STRUCTURE_BLOCKDIAGONAL

ARMPL_SPARSE_STRUCTURE_BANDED

ARMPL_SPARSE_STRUCTURE_TRIANGULAR

ARMPL_SPARSE_STRUCTURE_BLOCKTRIANGULAR

ARMPL_SPARSE_STRUCTURE_HERMITIAN

ARMPL_SPARSE_STRUCTURE_HPCG

- ARMPL_SPARSE_HINT_TYPE``==``ARMPL_SPARSE_HINT_SPMV_INVOCATIONS

  ARMPL_SPARSE_INVOCATIONS_SINGLE

  ARMPL_SPARSE_INVOCATIONS_FEW

  ARMPL_SPARSE_INVOCATIONS_MANY (*)

- ARMPL_SPARSE_HINT_TYPE``==``ARMPL_SPARSE_HINT_SPMV_OPERATION

  ARMPL_SPARSE_OPERATION_NOTRANS (*)

  ARMPL_SPARSE_OPERATION_TRANS

  ARMPL_SPARSE_OPERATION_CONJTRANS

Note: If the armpl_spmat object was created using the ARMPL_SPARSE_CREATE_NOCOPY flag then that specfication takes precedence over the ARMPL_SPARSE_MEMORY_ALLOCS hint.

6.3.18 armpl_spmv_optimize

armpl_spmv_optimize performs optimizations on a previously created Arm Performance Libraries sparse matrix object appropriate to an SpMV operation.

This will use any previously supplied hints coming from *armpl_spmat_hint*.

This function does not perform the SpMV itself and will potentially create new data-structures inside the sparse matrix object.

These will contain alternative representations of the supplied sparse matrix in order to later calculate the SpMV operation more efficiently.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmv_optimize(armpl_spmat_t A);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmv_optimize(A, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(in) :: A
         integer, intent(out) :: info
end subroutine armpl_spmv_optimize
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Input and output parameter

`A` is `armpl_spmat_t`

`A` is a sparse matrix structure.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*()` function.

6.3.19 armpl_spmv_exec_c

armpl_spmv_exec_c performs one of the sparse matrix-vector operations

```
y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is a sparse matrix.

The sparse matrix, A, should have previously been created using a routine such as **armpl_spmat_create_csr_c**. It is not necessary to supply hints, using **armpl_spmv_hint()**, although it is recommended as the default settings might not be appropriate in every use-case. The optimize phase, **armpl_spmv_optimize()**, might be applied on the first execution of **armpl_spmv_exec_c** if it has not already been explicitly called by the user.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmv_exec_c(enum sparse_hint_value trans,
                                 armpl_singlecomplex_t alpha,
                                 armpl_spmat_t A,
                                 const armpl_singlecomplex_t *x,
                                 armpl_singlecomplex_t beta,
                                 armpl_singlecomplex_t *y);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmv_exec(trans, alpha, A, x, beta, y, info)
         use armpl_kinds
         integer(kind=armpl_i4), intent(in) :: trans
         complex(kind=armpl_r32), intent(in) :: alpha
         integer(kind=armpl_i8), intent(in) :: A
         complex(kind=armpl_r32), intent(in) :: x(*)
         complex(kind=armpl_r32), intent(in) :: beta
         complex(kind=armpl_r32), intent(inout) :: y(*)
         integer, intent(out) :: info
end subroutine armpl_spmv_exec
```

Returns

In C/C++ this function returns an `armpl_status_t` which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`trans`

Input parameter

`trans` is `enum sparse_hint_value`

`trans` describes the transpose operation to be performed on the sparse matrix A before calculating the matrix-vector multiplication.

Constraint: `trans` is either `ARMPL_SPARSE_OPERATION_NOTRANS`, `ARMPL_SPARSE_OPERATION_TRANS` or `ARMPL_SPARSE_OPERATION_CONJTRANS` for no transpose, transpose or performing a conjugate transpose, respectively.

`alpha` Input parameter

`alpha` is `armpl_singlecomplex_t`

`alpha` specifies the constant which premultiples the matrix A.

`A` Input and output parameter

`A` is `armpl_spmat`

`A` is a sparse matrix structure.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*_c()` function.

`x` Input parameter

`x` is `armpl_singlecomplex_t*`

`x` is the (dense) vector to be multiplied by the matrix A.

Constraint: `x` is a previously allocated array. This has length determined by the transpose type specified in `trans`. This length is given in terms of the dimensions of the sparse matrix object created in a `armpl_spmat_create_*_c` function: namely of length `n` when `trans=ARMPL_SPARSE_OPERATION_NOTRANS` and length `m` otherwise.

beta Input parameter

beta is armpl_singlecomplex_t

beta specifies the scalar to multiply each entry of the vector, y

Constraint: If beta = 0 then the array y is output only.

y Input and output parameter

y is armpl_singlecomplex_t

y gives the output of the sparse matrix-vector multiplication.

Constraint: y is a previously allocated array. This has length determined by the transpose type specified in trans. This length is given in terms of the dimensions of the sparse matrix object created in a armpl_spmat_create_*_c function: namely of length m when trans=ARMPL_SPARSE_OPERATION_NOTRANS and length n otherwise.

6.3.20 armpl_spmv_exec_d

armpl_spmv_exec_d performs one of the sparse matrix-vector operations

```
y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is a sparse matrix.

The sparse matrix, A, should have previously been created using a routine such as **armpl_spmat_create_csr_d**. It is not necessary to supply hints, using **armpl_spmv_hint()**, although it is recommended as the default settings might not be appropriate in every use-case. The optimize phase, **armpl_spmv_optimize()**, might be applied on the first execution of **armpl_spmv_exec_d** if it has not already been explicitly called by the user.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmv_exec_d(enum sparse_hint_value trans, double alpha,
                                 armpl_spmat_t A, const double *x,
                                 double beta, double *y);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmv_exec(trans, alpha, A, x, beta, y, info)
         use armpl_kinds
         integer(kind=armpl_i4), intent(in) :: trans
         real(kind=armpl_r64), intent(in) :: alpha
               integer(kind=armpl_i8), intent(in) :: A
         real(kind=armpl_r64), intent(in) :: x(*)
         real(kind=armpl_r64), intent(in) :: beta
         real(kind=armpl_r64), intent(inout) :: y(*)
         integer, intent(out) :: info
end subroutine armpl_spmv_exec
```

Returns

In C/C++, this function returns an armpl_status_t, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter info.

Possible return values are:

- **ARMPL_STATUS_SUCCESS** The function returned with no errors.
- **ARMPL_STATUS_INPUT_PARAMETER_ERROR** An error was found with the supplied input parameters.
- **ARMPL_STATUS_EXECUTION_FAILURE** The function failed for an alternative reason.

Parameters

`trans`

Input parameter

`trans` is `enum sparse_hint_value`

`trans` describes the transpose operation to be performed on the sparse matrix A before calculating the matrix-vector multiplication.

Constraint: `trans` is either `ARMPL_SPARSE_OPERATION_NOTRANS`, `ARMPL_SPARSE_OPERATION_TRANS` or `ARMPL_SPARSE_OPERATION_CONJTRANS` for no transpose, transpose or performing a conjugate transpose, respectively.

alpha Input parameter

`alpha` is `double`

`alpha` specifies the constant which premultiples the matrix A.

A Input and output parameter

`A` is `armpl_spmat`

`A` is a sparse matrix structure.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*_d()` function.

x Input parameter

`x` is `double*`

`x` is the (dense) vector to be multiplied by the matrix A.

Constraint: `x` is a previously allocated array. This has length determined by the transpose type specified in `trans`. This length is given in terms of the dimensions of the sparse matrix object created in a `armpl_spmat_create_*_d` function: namely of length `n` when `trans=ARMPL_SPARSE_OPERATION_NOTRANS` and length `m` otherwise.

beta Input parameter

`beta` is `double`

`beta` specifies the scalar to multiply each entry of the vector, `y`.

Constraint: If `beta` = 0 then the array `y` is output only.

y Input and output parameter

`y` is `double`

`y` gives the output of the sparse matrix-vector multiplication.

Constraint: `y` is a previously allocated array. This has length determined by the transpose type specified in `trans`. This length is given in terms of the dimensions of the sparse matrix object created in a `armpl_spmat_create_*_d` function: namely of length `m` when `trans=ARMPL_SPARSE_OPERATION_NOTRANS` and length `n` otherwise.

6.3.21 armpl_spmv_exec_s

armpl_spmv_exec_s performs one of the sparse matrix-vector operations

```
y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is a sparse matrix.

The sparse matrix, A, should have previously been created using a routine such as **armpl_spmat_create_csr_s**. It is not necessary to supply hints, using **armpl_spmv_hint**(), although it is recommended as the default settings might not be appropriate in every use-case. The optimize phase, **armpl_spmv_optimize**(), might be applied on the first execution of **armpl_spmv_exec_s** if it has not already been explicitly called by the user.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmv_exec_s(enum sparse_hint_value trans, float alpha,
                                 armpl_spmat_t A, const float *x, float beta,
                                 float *y);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmv_exec(trans, alpha, A, x, beta, y, info)
         use armpl_kinds
         integer(kind=armpl_i4), intent(in) :: trans
         real(kind=armpl_r32), intent(in) :: alpha
         integer(kind=armpl_i8), intent(in) :: A
         real(kind=armpl_r32), intent(in) :: x(*)
               real(kind=armpl_r32), intent(in) :: beta
         real(kind=armpl_r32), intent(inout) :: y(*)
         integer, intent(out) :: info
end subroutine armpl_spmv_exec
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`trans` Input parameter

`trans` is `enum sparse_hint_value`

`trans` describes the transpose operation to be performed on the sparse matrix A before calculating the matrix-vector multiplication.

Constraint: `trans` is either `ARMPL_SPARSE_OPERATION_NOTRANS`, `ARMPL_SPARSE_OPERATION_TRANS` or `ARMPL_SPARSE_OPERATION_CONJTRANS` for no transpose, transpose or performing a conjugate transpose, respectively.

`alpha` Input parameter

`alpha` is `float`

`alpha` specifies the constant which premultiples the matrix A.

`A` Input and output parameter

`A` is `armpl_spmat`

`A` is a sparse matrix structure.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*_s()` function.

`x`

Input parameter

`x` is `float*`

`x` is the (dense) vector to be multiplied by the matrix A.

Constraint: `x` is a previously allocated array. This has length determined by the transpose type specified in `trans`. This length is given in terms of the dimensions of the sparse matrix object created in a `armpl_spmat_create_*_s` function: namely of length `n` when `trans=ARMPL_SPARSE_OPERATION_NOTRANS` and length `m` otherwise.

`beta` Input parameter

`beta` is `float`

`beta` specifies the scalar to multiply each entry of the vector, `y`.

Constraint: If `beta` = 0 then the array `y` is output only.

`y` Input and output parameter

`y` is `float`

`y` gives the output of the sparse matrix-vector multiplication.

Constraint: `y` is a previously allocated array. This has length determined by the transpose type specified in `trans`. This length is given in terms of the dimensions of the sparse matrix object created in a `armpl_spmat_create_*_s` function: namely of length `m` when `trans=ARMPL_SPARSE_OPERATION_NOTRANS` and length `n` otherwise.

6.3.22 armpl_spmv_exec_z

armpl_spmv_exec_z performs one of the sparse matrix-vector operations

```
y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,
```

where alpha and beta are scalars, x and y are vectors and A is a sparse matrix.

The sparse matrix, A, should have previously been created using a routine such as **armpl_spmat_create_csr_z**. It is not necessary to supply hints, using **armpl_spmv_hint**(), although it is recommended as the default settings might not be appropriate in every use-case. The optimize phase, **armpl_spmv_optimize**(), might be applied on the first execution of **armpl_spmv_exec_z** if it has not already been explicitly called by the user.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmv_exec_z(enum sparse_hint_value trans,
                                 armpl_doublecomplex_t alpha,
                                 armpl_spmat_t A,
                                 onst armpl_doublecomplex_t *x,
                                 armpl_doublecomplex_t beta,
                                 armpl_doublecomplex_t *y);
```

Fortran 2003 specification:

```
use armpl_library

subroutine armpl_spmv_exec(trans, alpha, A, x, beta, y, info)
         use armpl_kinds
         implicit none
         integer(kind=armpl_i4), intent(in) :: trans
         complex(kind=armpl_r64), intent(in) :: alpha
         integer(kind=armpl_i8), intent(in) :: A
         complex(kind=armpl_r64), intent(in) :: x(*)
         complex(kind=armpl_r64), intent(in) :: beta
         complex(kind=armpl_r64), intent(inout) :: y(*)
         integer, intent(out) :: info
end subroutine armpl_spmv_exec
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`trans`

Input parameter

`trans` is `enum sparse_hint_value`

`trans` describes the transpose operation to be performed on the sparse matrix A before calculating the matrix-vector multiplication.

Constraint: `trans` is either `ARMPL_SPARSE_OPERATION_NOTRANS`, `ARMPL_SPARSE_OPERATION_TRANS` or `ARMPL_SPARSE_OPERATION_CONJTRANS` for no transpose, transpose or performing a conjugate transpose, respectively.

`alpha` Input parameter

`alpha` is `armpl_doublecomplex_t`

`alpha` specifies the constant which premultiples the matrix A.

A Input and output parameter

A is armpl_spmat

A is a sparse matrix structure.

Constraint: The sparse matrix A should have been previously created using an appropriate armpl_spmat_create_*_z() function

x Input parameter

x is armpl_doublecomplex_t*

x is the (dense) vector to be multiplied by the matrix A.

Constraint: x is a previously allocated array. This has length determined by the transpose type specified in trans. This length is given in terms of the dimensions of the sparse matrix object created in a armpl_spmat_create_*_z function: namely of length n when trans=ARMPL_SPARSE_OPERATION_NOTRANS and length m otherwise.

beta Input parameter

beta is armpl_doublecomplex_t

beta specifies the scalar to multiply each entry of the vector, y, on input.

Constraint: If beta = 0 then the array y is output only.

y Input and output parameter

y is armpl_doublecomplex_t

y gives the output of the sparse matrix-vector multiplication.

Constraint: y is a previously allocated array. This has length determined by the transpose type specified in trans. This length is given in terms of the dimensions of the sparse matrix object created in a armpl_spmat_create_*_z function: namely of length m when trans=ARMPL_SPARSE_OPERATION_NOTRANS and length n otherwise.

6.3.23 armpl_spmat_destroy

armpl_spmat_destroy frees all memory associated with the supplied Arm Performance Libraries sparse matrix structure.

Syntax

C specification:

```
#include "armpl.h"

armpl_status_t armpl_spmat_destroy(armpl_spmat_t A);
```

Fortran 2003 specification:

```
use armpl_library

      subroutine armpl_spmat_destroy(A, info)
         use armpl_kinds
         integer(kind=armpl_i8), intent(inout) :: A
         integer, intent(out) :: info
end subroutine armpl_spmat_destroy
```

Returns

In C/C++, this function returns an `armpl_status_t`, which can be tested to check that the function returned correctly. In Fortran, this value is stored in the parameter `info`.

Possible return values are:

- **`ARMPL_STATUS_SUCCESS`** The function returned with no errors.
- **`ARMPL_STATUS_INPUT_PARAMETER_ERROR`** An error was found with the supplied input parameters.
- **`ARMPL_STATUS_EXECUTION_FAILURE`** The function failed for an alternative reason.

Parameters

`A` Input and output parameter

`A` is `armpl_spmat`

`A` is a sparse matrix structure.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*()` function.

Constraint: The sparse matrix `A` should have been previously created using an appropriate `armpl_spmat_create_*()` function and should not be used again
