If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

4.17.160 ctfsm

Level 3 BLAS like routine for A in RFP Format.

ctfsm solves the matrix equation

```
op( A )*X = alpha*B  or  X*op( A ) = alpha*B
```

where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**H.
```

A is in Rectangular Full Packed (RFP) Format.

The matrix X is overwritten on B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctfsm(TRANSR, SIDE, UPLO, TRANS, DIAG, M, N, ALPHA, A, B, LDB)
```

C specification:

```
#include "armpl.h"

void ctfsm_(const char *transr, const char *side, const char *uplo,
            const char *trans, const char *diag, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_singlecomplex_t *alpha,
            const armpl_singlecomplex_t *a, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal Form of RFP A is stored; = 'C': The Conjugate-transpose Form of RFP A is stored.

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l' op(A)*X = alpha*B.

SIDE = 'R' or 'r' X*op(A) = alpha*B.

Unchanged on exit.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the RFP matrix A came from an upper or lower triangular matrix as follows: UPLO = 'U' or 'u' RFP A came from an upper triangular matrix UPLO = 'L' or 'l' RFP A came from a lower triangular matrix

Unchanged on exit.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANS = 'N' or 'n' op(A) = A.

TRANS = 'C' or 'c' op(A) = conjg(A').

Unchanged on exit.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not RFP A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A Input parameter.

A is COMPLEX

A is an array, dimension (N*(N+1)/2). NT = N*(N+1)/2. On entry, the matrix A in RFP Format. RFP Format is described by TRANSR, UPLO and N as follows: If TRANSR='N' then RFP A is (0:N,0:K-1) when N is even; K=N/2. RFP A is (0:N-1,0:K) when N is odd; K=N/2. If TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the NT elements of upper packed A either in normal or conjugate-transpose Format. If UPLO = 'L' the RFP A contains the NT elements of lower packed A either in normal or conjugate-transpose Format. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and is N when is odd. See the Note below for more details. Unchanged on exit.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m). Unchanged on exit.

Related Information

For this routine in other precisions, please see *dtfsm*, *stfsm* and *ztfsm*. It also exists with a native C interface as *LAPACKE_ctfsm*.

4.17.161 ctfttp

ctfttp copies a triangular matrix A from rectangular full packed format (TF) to standard packed format (TP).

Syntax

Fortran specification:

```
use armpl_library

subroutine ctfttp(TRANSR, UPLO, N, ARF, AP, INFO)
```

C specification:

```
#include "armpl.h"

void ctfttp_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *arf, armpl_singlecomplex_t *ap,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF is in Normal format; = 'C': ARF is in Conjugate-transpose format;

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ARF Input parameter.

ARF is COMPLEX

ARF is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

AP Output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtfttp*, *stfttp* and *ztfttp*. It also exists with a native C interface as *LAPACKE_ctfttp*.

4.17.162 ctfttr

ctfttr copies a triangular matrix A from rectangular full packed format (TF) to standard full format (TR).

Syntax

Fortran specification:

```
use armpl_library

subroutine ctfttr(TRANSR, UPLO, N, ARF, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void ctfttr_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *arf, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF is in Normal format; = 'C': ARF is in Conjugate-transpose format;

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ARF Input parameter.

ARF is COMPLEX

ARF is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

A Output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtfttr*, *stfttr* and *ztfttr*. It also exists with a native C interface as *LAPACKE_ctfttr*.

4.17.163 ctgex2

`ctgex2` swaps adjacent diagonal 1 by 1 blocks (A11,B11) and (A22,B22) in an upper triangular matrix pair (A, B) by an unitary equivalence transformation.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)**H = Q(out) * A(out) * Z(out)**H
Q(in) * B(in) * Z(in)**H = Q(out) * B(out) * Z(out)**H
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ctgex2(WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, J1, INFO)
```

C specification:

```
#include "armpl.h"

void ctgex2_(const armpl_int_t *wantq, const armpl_int_t *wantz,
             const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *q,
             const armpl_int_t *ldq, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, const armpl_int_t *j1,
             armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

`WANTQ` is `LOGICAL`

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update `Q`.

WANTZ Input parameter.

`WANTZ` is `LOGICAL`

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update `Z`.

N Input parameter.

`N` is `INTEGER`

The order of the matrices `A` and `B`. `N` >= 0.

A Input and output parameter.

`A` is `COMPLEX`

`A` is an array, dimension (`LDA`, `N`). On entry, the matrix `A` in the pair (`A`, B). On exit, the updated matrix `A`.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, the updated matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). If WANTQ = .TRUE, on entry, the unitary matrix Q. On exit, the updated matrix Q. Not referenced if WANTQ = .FALSE..

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If WANTZ = .TRUE, on entry, the unitary matrix Z. On exit, the updated matrix Z. Not referenced if WANTZ = .FALSE..

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

J1 Input parameter.

J1 is INTEGER

The index to the first block (A11, B11).

INFO Output parameter.

INFO is INTEGER

=0: Successful exit. =1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill- conditioned.

Related Information

For this routine in other precisions, please see *dtgex2*, *stgex2* and *ztgex2*.

4.17.164 ctgsy2

ctgsy2 solves the generalized Sylvester equation

```
A * R - L * B = scale *  C                (1)
D * R - L * E = scale * F
```

using Level 1 and 2 BLAS, where R and L are unknown M-by-N matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size M-by-M, N-by-N and M-by-N, respectively. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation solving equation (1) corresponds to solve Zx = scale * b, where Z is defined as

```
Z = [ kron(In, A)  -kron(B**H, Im) ]             (2)
    [ kron(In, D)  -kron(E**H, Im) ],
```

Ik is the identity matrix of size k and X^H is the transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y.

If TRANS = 'C', y in the conjugate transposed system Z^H *y = scale*b is solved for, which is equivalent to solve for R and L in

```
 A**H * R  + D**H * L   = scale * C           (3)
R  * B**H + L  * E**H  = scale * -F
```

This case is used to compute an estimate of Dif[(A, D), (B, E)] = = sigma_min(Z) using reverse communicaton with CLACON.

`ctgsy2` also (IJOB >= 1) contributes to the computation in CTGSYL of an upper bound on the separation between to matrix pairs. Then the input (A, D), (B, E) are sub-pencils of two matrix pairs in CTGSYL.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctgsy2(TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD, E, LDE,
                  F, LDF, SCALE, RDSUM, RDSCAL, INFO)
```

C specification:

```
#include "armpl.h"

void ctgsy2_(const char *trans, const armpl_int_t *ijob, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, const armpl_singlecomplex_t *d,
             const armpl_int_t *ldd, const armpl_singlecomplex_t *e,
             const armpl_int_t *lde, armpl_singlecomplex_t *f,
             const armpl_int_t *ldf, float *scale, float *rdsum,
             float *rdscal, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N', solve the generalized Sylvester equation (1). = 'T': solve the 'transposed' system (3).

IJOB Input parameter.

IJOB is INTEGER

Specifies what kind of functionality to be performed. =0: solve (1) only. =1: A contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed. (look

ahead strategy is used). =2: A contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed. (SGECON on sub-systems is used.) Not referenced if TRANS = 'T'.

M Input parameter.

M is INTEGER

On entry, M specifies the order of A and D, and the row dimension of C, F, R and L.

N Input parameter.

N is INTEGER

On entry, N specifies the order of B and E, and the column dimension of C, F, R and L.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, M). On entry, A contains an upper triangular matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the matrix A. LDA >= max(1, M).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, B contains an upper triangular matrix.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the matrix B. LDB >= max(1, N).

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, C contains the right-hand-side of the first matrix equation in (1). On exit, if IJOB = 0, C has been overwritten by the solution R.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the matrix C. LDC >= max(1, M).

D Input parameter.

D is COMPLEX

D is an array, dimension (LDD, M). On entry, D contains an upper triangular matrix.

LDD Input parameter.

LDD is INTEGER

The leading dimension of the matrix D. LDD >= max(1, M).

E Input parameter.

E is COMPLEX

E is an array, dimension (LDE, N). On entry, E contains an upper triangular matrix.

LDE Input parameter.

LDE is INTEGER

The leading dimension of the matrix E. LDE >= max(1, N).

F Input and output parameter.

F is COMPLEX

F is an array, dimension (LDF, N). On entry, F contains the right-hand-side of the second matrix equation in (1). On exit, if IJOB = 0, F has been overwritten by the solution L.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the matrix F. LDF >= max(1, M).

SCALE Output parameter.

SCALE is REAL

On exit, 0 <= SCALE <= 1. If 0 < SCALE < 1, the solutions R and L (C and F on entry) will hold the solutions to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If SCALE = 0, R and L will hold the solutions to the homogeneous system with C = F = 0. Normally, SCALE = 1.

RDSUM Input and output parameter.

RDSUM is REAL

On entry, the sum of squares of computed contributions to the Dif-estimate under computation by CTGSYL, where the scaling factor RDSCAL (see below) has been factored out. On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If TRANS = 'T' RDSUM is not touched. NOTE: RDSUM only makes sense when CTGSY2 is called by CTGSYL.

RDSCAL Input and output parameter.

RDSCAL is REAL

On entry, scaling factor used to prevent overflow in RDSUM. On exit, RDSCAL is updated w.r.t. the current contributions in RDSUM. If TRANS = 'T', RDSCAL is not touched. NOTE: RDSCAL only makes sense when CTGSY2 is called by CTGSYL.

INFO Output parameter.

INFO is INTEGER

On exit, if INFO is set to =0: Successful exit <0: If INFO = -i, input argument number i is illegal. >0: The matrix pairs (A, D) and (B, E) have common or very close eigenvalues.

Related Information

For this routine in other precisions, please see *dtgsy2*, *stgsy2* and *ztgsy2*.

4.17.165 ctplqt2

ctplqt2 computes a LQ a factorization of a complex "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctplqt2(M, N, L, A, LDA, B, LDB, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void ctplqt2_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *l, armpl_singlecomplex_t *a,
              const armpl_int_t *lda, armpl_singlecomplex_t *b,
              const armpl_int_t *ldb, armpl_singlecomplex_t *t,
              const armpl_int_t *ldt, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The total number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the lower trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, M). On entry, the lower triangular M-by-M matrix A. On exit, the elements on and below the diagonal of the array contain the lower triangular matrix L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first N-L columns are rectangular, and the last L columns are lower trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, M). The N-by-N upper triangular factor T of the block reflector. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, M)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtplqt2*, *stplqt2* and *ztplqt2*.

4.17.166 ctpqrt2

ctpqrt2 computes a QR factorization of a complex "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctpqrt2(M, N, L, A, LDA, B, LDB, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void ctpqrt2_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *l, armpl_singlecomplex_t *a,
              const armpl_int_t *lda, armpl_singlecomplex_t *b,
              const armpl_int_t *ldb, armpl_singlecomplex_t *t,
              const armpl_int_t *ldt, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The total number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the upper trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the upper triangular N-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first M-L rows are rectangular, and the last L rows are upper trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). The N-by-N upper triangular factor T of the block reflector. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtpqrt2*, *stpqrt2* and *ztpqrt2*. It also exists with a native C interface as *LAPACKE_ctpqrt2*.

4.17.167 ctprfb

ctprfb applies a complex "triangular-pentagonal" block reflector H or its conjugate transpose H^H to a complex matrix C, which is composed of two blocks A and B, either from the left or right.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctprfb(SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV, T, LDT, A,
                  LDA, B, LDB, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void ctprfb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *k, const armpl_int_t *l,
                const armpl_singlecomplex_t *v, const armpl_int_t *ldv,
                const armpl_singlecomplex_t *t, const armpl_int_t *ldt,
                armpl_singlecomplex_t *a, const armpl_int_t *lda,
                armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                armpl_singlecomplex_t *work, const armpl_int_t *ldwork, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^H from the Left = 'R': apply H or H^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'C': apply H^H (Conjugate transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columns = 'R': Rows

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The order of the matrix T, i.e. the number of elementary reflectors whose product defines the block reflector. K >= 0.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

V Input parameter.

V is COMPLEX

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, M) if STOREV = 'R' and SIDE = 'L' (LDV, N) if STOREV = 'R' and SIDE = 'R' The pentagonal matrix V, which contains the elementary reflectors H(1), H(2), . . . , H(K). See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C' and SIDE = 'L', LDV >= max(1, M); if STOREV = 'C' and SIDE = 'R', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

T Input parameter.

T is COMPLEX

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

A Input and output parameter.

A is COMPLEX

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of H*C or H^H *C or C*H or C*H^H . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of H*C or H^H *C or C*H or C*H^H . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension. (LDWORK, N) if SIDE = 'L', (LDWORK, K) if SIDE = 'R'.

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= K; if SIDE = 'R', LDWORK >= M.

Related Information

For this routine in other precisions, please see *dtprfb*, *stprfb* and *ztprfb*. It also exists with a native C interface as *LAPACKE_ctprfb*.

4.17.168 ctpttf

ctpttf copies a triangular matrix A from standard packed format (TP) to rectangular full packed format (TF).

Syntax

Fortran specification:

```
use armpl_library

subroutine ctpttf(TRANSR, UPLO, N, AP, ARF, INFO)
```

C specification:

```
#include "armpl.h"

void ctpttf_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *ap, armpl_singlecomplex_t *arf,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF in Normal format is wanted; = 'C': ARF in Conjugate-transpose format is wanted.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

ARF Output parameter.

ARF is COMPLEX

ARF is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtpttf*, *stpttf* and *ztpttf*. It also exists with a native C interface as *LAPACKE_ctpttf*.

4.17.169 ctpttr

ctpttr copies a triangular matrix A from standard packed format (TP) to standard full format (TR).

Syntax

Fortran specification:

```
use armpl_library

subroutine ctpttr(UPLO, N, AP, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void ctpttr_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *ap, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular. = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

A Output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtpttr*, *stpttr* and *ztpttr*. It also exists with a native C interface as *LAPACKE_ctpttr*.

4.17.170 ctrti2

`ctrti2` computes the inverse of a complex upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrti2(UPLO, DIAG, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void ctrti2_(const char *uplo, const char *diag, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the matrix `A` is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

`DIAG` is `CHARACTER*1`

Specifies whether or not the matrix `A` is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `COMPLEX`

`A` is an array, dimension (`LDA`, `N`). On entry, the triangular matrix `A`. If `UPLO` = 'U', the leading n by n upper triangular part of the array `A` contains the upper triangular matrix, and the strictly lower triangular part of `A` is not referenced. If `UPLO` = 'L', the leading n by n lower triangular part of the array `A` contains the lower triangular matrix, and the strictly upper triangular part of `A` is not referenced. If `DIAG` = 'U', the diagonal elements of `A` are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `N`).

INFO Output parameter.

`INFO` is `INTEGER`

= 0: successful exit < 0: if `INFO` = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrti2*, *strti2* and *ztrti2*.

4.17.171 ctrttf

`ctrttf` copies a triangular matrix A from standard full format (TR) to rectangular full packed format (TF) .

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrttf(TRANSR, UPLO, N, A, LDA, ARF, INFO)
```

C specification:

```
#include "armpl.h"

void ctrttf_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *arf, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF in Normal mode is wanted; = 'C': ARF in Conjugate Transpose mode is wanted;

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the matrix A. LDA >= max(1, N).

ARF Output parameter.

ARF is COMPLEX

ARF is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrttf*, *strttf* and *ztrttf*. It also exists with a native C interface as *LAPACKE_ctrttf*.

4.17.172 ctrttp

ctrttp copies a triangular matrix A from full format (TR) to standard packed format (TP).

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrttp(UPLO, N, A, LDA, AP, INFO)
```

C specification:

```
#include "armpl.h"

void ctrttp_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrices AP and A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AP Output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrttp*, *strttp* and *ztrttp*. It also exists with a native C interface as *LAPACKE_ctrttp*.

4.17.173 cunbdb1

cunbdb1 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                        [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                        [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. Q must be no larger than P, M-P, or M-Q. Routines CUNBDB2, CUNBDB3, and CUNBDB4 handle cases in which Q is not the minimum dimension.

The unitary matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are Q-by-Q bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunbdb1(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunbdb1_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, armpl_singlecomplex_t *x11,
              const armpl_int_t *ldx11, armpl_singlecomplex_t *x21,
              const armpl_int_t *ldx21, float *theta, float *phi,
              armpl_singlecomplex_t *taup1, armpl_singlecomplex_t *taup2,
              armpl_singlecomplex_t *tauq1, armpl_singlecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= MIN(P,M-P,M-Q).

X11 Input and output parameter.

X11 is COMPLEX

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is COMPLEX

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zunbdb1*.

4.17.174 cunbdb2

cunbdb2 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                        [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                        [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. P must be no larger than M-P, Q, or M-Q. Routines CUNBDB1, CUNBDB3, and CUNBDB4 handle cases in which P is not the minimum dimension.

The unitary matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are P-by-P bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunbdb2(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunbdb2_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, armpl_singlecomplex_t *x11,
              const armpl_int_t *ldx11, armpl_singlecomplex_t *x21,
              const armpl_int_t *ldx21, float *theta, float *phi,
              armpl_singlecomplex_t *taup1, armpl_singlecomplex_t *taup2,
              armpl_singlecomplex_t *tauq1, armpl_singlecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= min(M-P, Q,M-Q).

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is COMPLEX

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is COMPLEX

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zunbdb2*.

4.17.175 cunbdb3

cunbdb3 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                         [ B11 ]
[ X11 ]   [ P1 |    ]   [  0  ]
[-----] = [---------]   [-----] Q1**T .
[ X21 ]   [    | P2 ]   [ B21 ]
                         [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. M-P must be no larger than P, Q, or M-Q. Routines CUNBDB1, CUNBDB2, and CUNBDB4 handle cases in which M-P is not the minimum dimension.

The unitary matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are (M-P)-by-(M-P) bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunbdb3(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunbdb3_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, armpl_singlecomplex_t *x11,
              const armpl_int_t *ldx11, armpl_singlecomplex_t *x21,
              const armpl_int_t *ldx21, float *theta, float *phi,
              armpl_singlecomplex_t *taup1, armpl_singlecomplex_t *taup2,
              armpl_singlecomplex_t *tauq1, armpl_singlecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M. M-P <= min(P, Q,M-Q).

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is COMPLEX

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is COMPLEX

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zunbdb3*.

4.17.176 cunbdb4

cunbdb4 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                        [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                        [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. M-Q must be no larger than P, M-P, or Q. Routines CUNBDB1, CUNBDB2, and CUNBDB3 handle cases in which M-Q is not the minimum dimension.

The unitary matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are (M-Q)-by-(M-Q) bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunbdb4(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, PHANTOM, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunbdb4_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, armpl_singlecomplex_t *x11,
              const armpl_int_t *ldx11, armpl_singlecomplex_t *x21,
              const armpl_int_t *ldx21, float *theta, float *phi,
              armpl_singlecomplex_t *taup1, armpl_singlecomplex_t *taup2,
              armpl_singlecomplex_t *tauq1, armpl_singlecomplex_t *phantom,
              armpl_singlecomplex_t *work, const armpl_int_t *lwork,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M and M-Q <= min(P,M-P, Q).

X11 Input and output parameter.

X11 is COMPLEX

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is COMPLEX

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

PHANTOM Output parameter.

PHANTOM is COMPLEX

PHANTOM is an array, dimension (M). The routine computes an M-by-1 column vector Y that is orthogonal to the columns of [X11; X21]. PHANTOM(1:P) and PHANTOM(P+1:M) contain Householder vectors for Y(1:P) and Y(P+1:M), respectively.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zunbdb4*.

4.17.177 cunbdb5

`cunbdb5` orthogonalizes the column vector

```
X = [ X1 ]
    [ X2 ]
```

with respect to the columns of

```
Q = [ Q1 ] .
    [ Q2 ]
```

The columns of Q must be orthonormal.

If the projection is zero according to Kahan's "twice is enough" criterion, then some other vector from the orthogonal complement is returned. This vector is chosen in an arbitrary but deterministic way.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunbdb5(M1, M2, N, X1, INCX1, X2, INCX2, Q1, LDQ1, Q2, LDQ2, WORK,
                   LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunbdb5_(const armpl_int_t *m1, const armpl_int_t *m2,
              const armpl_int_t *n, armpl_singlecomplex_t *x1,
              const armpl_int_t *incx1, armpl_singlecomplex_t *x2,
              const armpl_int_t *incx2, armpl_singlecomplex_t *q1,
              const armpl_int_t *ldq1, armpl_singlecomplex_t *q2,
              const armpl_int_t *ldq2, armpl_singlecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M1 Input parameter.

`M1` is `INTEGER`

The dimension of `X1` and the number of rows in `Q1`. 0 <= `M1`.

M2 Input parameter.

`M2` is `INTEGER`

The dimension of `X2` and the number of rows in `Q2`. 0 <= `M2`.

N Input parameter.

`N` is `INTEGER`

The number of columns in `Q1` and `Q2`. 0 <= `N`.

X1 Input and output parameter.

X1 is COMPLEX

X1 is an array, dimension (M1). On entry, the top part of the vector to be orthogonalized. On exit, the top part of the projected vector.

INCX1 Input parameter.

INCX1 is INTEGER

Increment for entries of X1.

X2 Input and output parameter.

X2 is COMPLEX

X2 is an array, dimension (M2). On entry, the bottom part of the vector to be orthogonalized. On exit, the bottom part of the projected vector.

INCX2 Input parameter.

INCX2 is INTEGER

Increment for entries of X2.

Q1 Input parameter.

Q1 is COMPLEX

Q1 is an array, dimension (LDQ1, N). The top part of the orthonormal basis matrix.

LDQ1 Input parameter.

LDQ1 is INTEGER

The leading dimension of Q1. LDQ1 >= M1.

Q2 Input parameter.

Q2 is COMPLEX

Q2 is an array, dimension (LDQ2, N). The bottom part of the orthonormal basis matrix.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of Q2. LDQ2 >= M2.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zunbdb5*.

4.17.178 cunbdb6

`cunbdb6` orthogonalizes the column vector

```
X = [ X1 ]
    [ X2 ]
```

with respect to the columns of

```
Q = [ Q1 ] .
    [ Q2 ]
```

The columns of Q must be orthonormal.

If the projection is zero according to Kahan's "twice is enough" criterion, then the zero vector is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunbdb6(M1, M2, N, X1, INCX1, X2, INCX2, Q1, LDQ1, Q2, LDQ2, WORK,
                   LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunbdb6_(const armpl_int_t *m1, const armpl_int_t *m2,
              const armpl_int_t *n, armpl_singlecomplex_t *x1,
              const armpl_int_t *incx1, armpl_singlecomplex_t *x2,
              const armpl_int_t *incx2, armpl_singlecomplex_t *q1,
              const armpl_int_t *ldq1, armpl_singlecomplex_t *q2,
              const armpl_int_t *ldq2, armpl_singlecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M1 Input parameter.

`M1` is `INTEGER`

The dimension of `X1` and the number of rows in `Q1`. 0 <= `M1`.

M2 Input parameter.

`M2` is `INTEGER`

The dimension of `X2` and the number of rows in `Q2`. 0 <= `M2`.

N Input parameter.

`N` is `INTEGER`

The number of columns in `Q1` and `Q2`. 0 <= `N`.

X1 Input and output parameter.

`X1` is `COMPLEX`

`X1` is an array, dimension (`M1`). On entry, the top part of the vector to be orthogonalized. On exit, the top part of the projected vector.

INCX1 Input parameter.

INCX1 is INTEGER

Increment for entries of X1.

X2 Input and output parameter.

X2 is COMPLEX

X2 is an array, dimension (M2). On entry, the bottom part of the vector to be orthogonalized. On exit, the bottom part of the projected vector.

INCX2 Input parameter.

INCX2 is INTEGER

Increment for entries of X2.

Q1 Input parameter.

Q1 is COMPLEX

Q1 is an array, dimension (LDQ1, N). The top part of the orthonormal basis matrix.

LDQ1 Input parameter.

LDQ1 is INTEGER

The leading dimension of Q1. LDQ1 >= M1.

Q2 Input parameter.

Q2 is COMPLEX

Q2 is an array, dimension (LDQ2, N). The bottom part of the orthonormal basis matrix.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of Q2. LDQ2 >= M2.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zunbdb6*.

4.17.179 cung2l

cung2l generates an m by n complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by CGEQLF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cung2l(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cung2l_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQLF in the last k columns of its array argument A. On exit, the m-by-n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *zung2l*.

4.17.180 cung2r

cung2r generates an m by n complex matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by CGEQRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cung2r(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cung2r_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CGEQRF in the first k columns of its array argument A. On exit, the m by n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *zung2r*.

4.17.181 cungl2

cungl2 generates an m-by-n complex matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

```
Q  =  H(k)**H . . . H(2)**H H(1)**H
```

as returned by CGELQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cungl2(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cungl2_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CGELQF in the first k rows of its array argument A. On exit, the m by n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *zungl2*.

4.17.182 cungr2

cungr2 generates an m by n complex matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

```
Q  =  H(1)**H H(2)**H . . . H(k)**H
```

as returned by CGERQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cungr2(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cungr2_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGERQF in the last k rows of its array argument A. On exit, the m-by-n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

4.17.183 cunm2l

cunm2l overwrites the general complex m-by-n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**H* C  if SIDE = 'L' and TRANS = 'C', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**H if SIDE = 'R' and TRANS = 'C',
```

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by CGEQLF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunm2l(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunm2l_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQLF in the last k columns of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by CGEQRF in the first k columns of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Q = H(k)**H . . . H(2)**H H(1)**H
```

as returned by CGELQF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunml2(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunml2_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGELQF in the first k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunml2*.

4.17.186 cunmr2

cunmr2 overwrites the general complex m-by-n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**H* C  if SIDE = 'L' and TRANS = 'C', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**H if SIDE = 'R' and TRANS = 'C',
```

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1)**H H(2)**H . . . H(k)**H
```

as returned by CGERQF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmr2(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunmr2_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
```

(continues on next page)

(continued from previous page)

```
            const armpl_int_t *ldc, armpl_singlecomplex_t *work,
            armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGERQF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunmr2*.

4.17.187 cunmr3

cunmr3 overwrites the general complex m by n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**H* C  if SIDE = 'L' and TRANS = 'C', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**H if SIDE = 'R' and TRANS = 'C',
```

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by CTZRZF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmr3(SIDE, TRANS, M, N, K, L, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunmr3_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const armpl_int_t *l,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CTZRZF.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunmr3*.

4.17.188 dgbtf2

dgbtf2 computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges. This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbtf2(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dgbtf2_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku, double *ab,
             const armpl_int_t *ldab, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgbtf2*, *sgbtf2* and *zgbtf2*.

4.17.189 dgebd2

dgebd2 reduces a real general m by n matrix A to upper or lower bidiagonal form B by an orthogonal transformation: $Q^T * A * P = B$.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgebd2(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgebd2_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *d, double *e, double *tauq,
             double *taup, double *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns in the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the m by n general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (min(M, N)-1). The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ Output parameter.

TAUQ is DOUBLE PRECISION

TAUQ is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

TAUP Output parameter.

TAUP is DOUBLE PRECISION

TAUP is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (max(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebd2*, *sgebd2* and *zgebd2*.

4.17.190 dgehd2

dgehd2 reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: $Q^T * A * Q = H$.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgehd2(N, ILO, IHI, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgehd2_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, double *a, const armpl_int_t *lda,
             double *tau, double *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to DGEBAL; otherwise they should be set to 1 and N respectively. See Further Details. 1 <= ILO <= IHI <= max(1, N).

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the n by n general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgehd2*, *sgehd2* and *zgehd2*.

4.17.191 dgelq2

dgelq2 computes an LQ factorization of a real m by n matrix A: A = L * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgelq2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgelq2_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *tau, double *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and below the diagonal of the array contain the m by min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelq2*, *sgelq2* and *zgelq2*. It also exists with a native C interface as *LAPACKE_dgelq2*.

4.17.192 dgelqt3

dgelqt3 recursively computes a LQ factorization of a real M-by-N matrix A, using the compact WY representation of Q.

Based on the algorithm of Elmroth and Gustavson, IBM J. Res. Develop. Vol 44 No. 4 July 2000.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine dgelqt3(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void dgelqt3_(const armpl_int_t *m, const armpl_int_t *n, double *a,
              const armpl_int_t *lda, double *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M =< N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the real M-by-N matrix A. On exit, the elements on and below the diagonal contain the N-by-N lower triangular matrix L; the elements above the diagonal are the rows of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelqt3*, *sgelqt3* and *zgelqt3*.

4.17.193 dgeql2

dgeql2 computes a QL factorization of a real m by n matrix A: A = Q * L.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeql2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeql2_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *tau, double *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the n by n lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the m by n lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeql2*, *sgeql2* and *zgeql2*.

4.17.194 dgeqr2

dgeqr2 computes a QR factorization of a real m by n matrix A: A = Q * R.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeqr2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqr2_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *tau, double *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and above the diagonal of the array contain the min(m,n) by n upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqr2*, *sgeqr2* and *zgeqr2*. It also exists with a native C interface as *LAPACKE_dgeqr2*.

4.17.195 dgeqr2p

dgeqr2p computes a QR factorization of a real m by n matrix A: A = Q * R. The diagonal entries of R are nonnegative.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeqr2p(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqr2p_(const armpl_int_t *m, const armpl_int_t *n, double *a,
              const armpl_int_t *lda, double *tau, double *work,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and above the diagonal of the array contain the min(m,n) by n upper trapezoidal matrix R (R is upper triangular if m >= n). The diagonal entries of R are nonnegative; the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqr2p*, *sgeqr2p* and *zgeqr2p*.

4.17.196 dgeqrt2

dgeqrt2 computes a QR factorization of a real M-by-N matrix A, using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeqrt2(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqrt2_(const armpl_int_t *m, const armpl_int_t *n, double *a,
              const armpl_int_t *lda, double *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the real M-by-N matrix A. On exit, the elements on and above the diagonal contain the N-by-N upper triangular matrix R; the elements below the diagonal are the columns of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrt2*, *sgeqrt2* and *zgeqrt2*. It also exists with a native C interface as *LAPACKE_dgeqrt2*.

4.17.197 dgeqrt3

dgeqrt3 recursively computes a QR factorization of a real M-by-N matrix A, using the compact WY representation of Q.

Based on the algorithm of Elmroth and Gustavson, IBM J. Res. Develop. Vol 44 No. 4 July 2000.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine dgeqrt3(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void dgeqrt3_(const armpl_int_t *m, const armpl_int_t *n, double *a,
              const armpl_int_t *lda, double *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the real M-by-N matrix A. On exit, the elements on and above the diagonal contain the N-by-N upper triangular matrix R; the elements below the diagonal are the columns of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrt3*, *sgeqrt3* and *zgeqrt3*. It also exists with a native C interface as *LAPACKE_dgeqrt3*.

4.17.198 dgerq2

`dgerq2` computes an RQ factorization of a real m by n matrix A: A = R * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgerq2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgerq2_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *tau, double *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). On entry, the m by n matrix `A`. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the m by m upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the m by n upper trapezoidal matrix R; the remaining elements, with the array `TAU`, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

TAU Output parameter.

`TAU` is `DOUBLE PRECISION`

`TAU` is an array, dimension (min(`M`, `N`)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

`WORK` is `DOUBLE PRECISION`

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgerq2*, *sgerq2* and *zgerq2*.

4.17.199 dgesc2

dgesc2 solves a system of linear equations

```
A * X = scale* RHS
```

with a general N-by-N matrix A using the LU factorization with complete pivoting computed by DGETC2.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgesc2(N, A, LDA, RHS, IPIV, JPIV, SCALE)
```

C specification:

```
#include "armpl.h"

void dgesc2_(const armpl_int_t *n, const double *a, const armpl_int_t *lda,
             double *rhs, const armpl_int_t *ipiv, const armpl_int_t *jpiv,
             double *scale);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the LU part of the factorization of the n-by-n matrix A computed by DGETC2: A = P * L * U * Q

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

RHS Input and output parameter.

RHS is DOUBLE PRECISION

RHS is an array, dimension (N).. On entry, the right hand side vector b. On exit, the solution vector X.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Input parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

SCALE Output parameter.

SCALE is DOUBLE PRECISION

On exit, SCALE contains the scale factor. SCALE is chosen 0 <= SCALE <= 1 to prevent owerflow in the solution.

Related Information

For this routine in other precisions, please see *cgesc2*, *sgesc2* and *zgesc2*.

4.17.200 dgetc2

dgetc2 computes an LU factorization with complete pivoting of the n-by-n matrix A. The factorization has the form A = P * L * U * Q, where P and Q are permutation matrices, L is lower triangular with unit diagonal elements and U is upper triangular.

This is the Level 2 BLAS algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgetc2(N, A, LDA, IPIV, JPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dgetc2_(const armpl_int_t *n, double *a, const armpl_int_t *lda,
             armpl_int_t *ipiv, armpl_int_t *jpiv, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the n-by-n matrix A to be factored. On exit, the factors L and U from the factorization A = P*L*U*Q; the unit diagonal elements of L are not stored. If U(k, k) appears to be less than SMIN, U(k, k) is given the value of SMIN, i.e., giving a nonsingular perturbed system.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension(N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Output parameter.

JPIV is INTEGER array, dimension(N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, U(k, k) is likely to produce owerflow if we try to solve for x in Ax = b. So U is perturbed to avoid the overflow.

Related Information

For this routine in other precisions, please see *cgetc2*, *sgetc2* and *zgetc2*.

4.17.201 dgetf2

dgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 2 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgetf2(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dgetf2_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgetf2*, *sgetf2* and *zgetf2*. It also exists with a native C interface as *LAPACKE_dgetf2*.

4.17.202 dgsvj0

dgsvj0 is called from DGESVJ as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as DGESVJ does, but it does not check convergence (stopping criterion). Few tuning parameters (marked by [TP]) are available for the implementer.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgsvj0(JOBV, M, N, A, LDA, D, SVA, MV, V, LDV, EPS, SFMIN, TOL,
                  NSWEEP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgsvj0_(const char *jobv, const armpl_int_t *m, const armpl_int_t *n,
             double *a, const armpl_int_t *lda, double *d, double *sva,
             const armpl_int_t *mv, double *v, const armpl_int_t *ldv,
             const double *eps, const double *sfmin, const double *tol,
             const armpl_int_t *nsweep, double *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether the output from this procedure is used to compute the matrix V: = 'V': the product of the Jacobi rotations is accumulated by postmulyiplying the N-by-N array V. (See the description of V.) = 'A': the product of the Jacobi rotations is accumulated by postmulyiplying the MV-by-N array V. (See the descriptions of MV and V.) = 'N': the Jacobi rotations are not accumulated.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, M-by-N matrix A, such that A*diag(D) represents the input matrix. On exit, A_onexit * D_onexit represents the input matrix A*diag(D) post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of D, TOL and NSWEEP.)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The array D accumulates the scaling factors from the fast scaled Jacobi rotations. On entry, A*diag(D) represents the input matrix. On exit, A_onexit*diag(D_onexit) represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of A, TOL and NSWEEP.)

SVA Input and output parameter.

SVA is DOUBLE PRECISION

SVA is an array, dimension (N). On entry, SVA contains the Euclidean norms of the columns of the matrix A*diag(D). On exit, SVA contains the Euclidean norms of the columns of the matrix onexit*diag(D_onexit).

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then MV is not referenced.

V Input and output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, N). If JOBV .EQ. 'V' then N rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV .EQ. 'A' then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V', LDV .GE. N. If JOBV = 'A', LDV .GE. MV.

EPS Input parameter.

EPS is DOUBLE PRECISION

EPS = DLAMCH('Epsilon')

SFMIN Input parameter.

SFMIN is DOUBLE PRECISION

SFMIN = DLAMCH('Safe Minimum')

TOL Input parameter.

TOL is DOUBLE PRECISION

TOL is the threshold for Jacobi rotations. For a pair A(:,p), A(:,q) of pivot columns, the Jacobi rotation is applied only if DABS(COS(angle(A(:,p),A(:,q)))) .GT. TOL.

NSWEEP Input parameter.

NSWEEP is INTEGER

NSWEEP is the number of sweeps of Jacobi rotations to be performed.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

LWORK is the dimension of WORK. LWORK .GE. M.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgsvj0*, *sgsvj0* and *zgsvj0*.

4.17.203 dgsvj1

dgsvj1 is called from DGESVJ as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as DGESVJ does, but it targets only particular pivots and it does not check convergence (stopping criterion). Few tunning parameters (marked by [TP]) are available for the implementer.

Further Details

dgsvj1 applies few sweeps of Jacobi rotations in the column space of the input M-by-N matrix A. The pivot pairs are taken from the (1,2) off-diagonal block in the corresponding N-by-N Gram matrix A^T * A. The block-entries (tiles) of the (1,2) off-diagonal block are marked by the [x]'s in the following scheme:

```
| *  *  * [x] [x] [x]|
| *  *  * [x] [x] [x]|    Row-cycling in the nblr-by-nblc [x] blocks.
| *  *  * [x] [x] [x]|    Row-cyclic pivoting inside each [x] block.
|[x] [x] [x] *  *  * |
|[x] [x] [x] *  *  * |
|[x] [x] [x] *  *  * |
```

In terms of the columns of A, the first N1 columns are rotated 'against' the remaining N-N1 columns, trying to increase the angle between the corresponding subspaces. The off-diagonal block is N1-by(N-N1) and it is tiled using quadratic tiles of side KBL. Here, KBL is a tunning parmeter. The number of sweeps is given in NSWEEP and the orthogonality threshold is given in TOL.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgsvj1(JOBV, M, N, N1, A, LDA, D, SVA, MV, V, LDV, EPS, SFMIN, TOL,
                  NSWEEP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgsvj1_(const char *jobv, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *n1, double *a, const armpl_int_t *lda,
             double *d, double *sva, const armpl_int_t *mv, double *v,
             const armpl_int_t *ldv, const double *eps, const double *sfmin,
             const double *tol, const armpl_int_t *nsweep, double *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether the output from this procedure is used to compute the matrix V: = 'V': the product of the Jacobi rotations is accumulated by postmulyiplying the N-by-N array V. (See the description of V.) = 'A': the product of the Jacobi rotations is accumulated by postmulyiplying the MV-by-N array V. (See the descriptions of MV and V.) = 'N': the Jacobi rotations are not accumulated.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

N1 Input parameter.

N1 is INTEGER

N1 specifies the 2 x 2 block partition, the first N1 columns are rotated 'against' the remaining N-N1 columns of A.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, M-by-N matrix A, such that A*diag(D) represents the input matrix. On exit, A_onexit * D_onexit represents the input matrix A*diag(D) post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of N1, D, TOL and NSWEEP.)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The array D accumulates the scaling factors from the fast scaled Jacobi rotations. On entry, A*diag(D) represents the input matrix. On exit, A_onexit*diag(D_onexit) represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of N1, A, TOL and NSWEEP.)

SVA Input and output parameter.

SVA is DOUBLE PRECISION

SVA is an array, dimension (N). On entry, SVA contains the Euclidean norms of the columns of the matrix A*diag(D). On exit, SVA contains the Euclidean norms of the columns of the matrix onexit*diag(D_onexit).

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then MV is not referenced.

V Input and output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, N). If JOBV .EQ. 'V' then N rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV .EQ. 'A' then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V', LDV .GE. N. If JOBV = 'A', LDV .GE. MV.

EPS Input parameter.

EPS is DOUBLE PRECISION

EPS = DLAMCH('Epsilon')

SFMIN Input parameter.

SFMIN is DOUBLE PRECISION

SFMIN = DLAMCH('Safe Minimum')

TOL Input parameter.

TOL is DOUBLE PRECISION

TOL is the threshold for Jacobi rotations. For a pair A(:,p), A(:,q) of pivot columns, the Jacobi rotation is applied only if DABS(COS(angle(A(:,p),A(:,q)))) .GT. TOL.

NSWEEP Input parameter.

NSWEEP is INTEGER

NSWEEP is the number of sweeps of Jacobi rotations to be performed.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

LWORK is the dimension of WORK. LWORK .GE. M.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgsvj1*, *sgsvj1* and *zgsvj1*.

4.17.204 dgtts2

dgtts2 solves one of the systems of equations

```
A*X = B  or  A**T*X = B,
```

with a tridiagonal matrix A using the LU factorization computed by DGTTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgtts2(ITRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB)
```

C specification:

```
#include "armpl.h"

void dgtts2_(const armpl_int_t *itrans, const armpl_int_t *n,
             const armpl_int_t *nrhs, const double *dl, const double *d,
             const double *du, const double *du2, const armpl_int_t *ipiv,
             double *b, const armpl_int_t *ldb);
```

Parameters

ITRANS Input parameter.

ITRANS is INTEGER

Specifies the form of the system of equations. = 0: A * X = B (No transpose) = 1: A^T * X = B (Transpose) = 2: A^T * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is DOUBLE PRECISION

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is DOUBLE PRECISION

DU is an array, dimension (N-1). The (n-1) elements of the first super-diagonal of U.

DU2 Input parameter.

DU2 is DOUBLE PRECISION

DU2 is an array, dimension (N-2). The (n-2) elements of the second super-diagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Related Information

For this routine in other precisions, please see *cgtts2*, *sgtts2* and *zgtts2*.

4.17.205 disnan

disnan returns .TRUE. if its argument is NaN, and .FALSE. otherwise. To be replaced by the Fortran 2003 intrinsic in the future.

Syntax

Fortran specification:

```
use armpl_library

logical function disnan(DIN)
```

C specification:

```
#include "armpl.h"

armpl_int_t disnan_(const double *din);
```

Parameters

DIN Input parameter.

DIN is DOUBLE PRECISION

Input to test for NaN.

Related Information

For this routine in other precisions, please see *sisnan*.

4.17.206 dla_gbamv

DLA_GBAMV performs one of the matrix-vector operations

```
     y := alpha*abs(A)*abs(x) + beta*abs(y),
or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine dla_gbamv(TRANS, M, N, KL, KU, ALPHA, AB, LDAB, X, INCX, BETA, Y,
                     INCY)
```

C specification:

```
#include "armpl.h"

void dla_gbamv_(const armpl_int_t *trans, const armpl_int_t *m,
                const armpl_int_t *n, const armpl_int_t *kl,
                const armpl_int_t *ku, const double *alpha, const double *ab,
                const armpl_int_t *ldab, const double *x,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *incx, const double *beta, double *y,
                const armpl_int_t *incy);
```

Parameters

TRANS Input parameter.

TRANS is INTEGER

On entry, TRANS specifies the operation to be performed as follows:

BLAS_NO_TRANS y := alpha*abs(A)*abs(x) + beta*abs(y) BLAS_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y) BLAS_CONJ_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y)

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, n). Before entry, the leading m by n part of the array AB must contain the matrix of coefficients. Unchanged on exit.

LDAB Input parameter.

LDAB is INTEGER

On entry, LDA specifies the first dimension of AB as declared in the calling (sub) program. LDAB must be at least max(1, m). Unchanged on exit.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Level 2 Blas routine.

4.17.207 dla_gbrcond

```
DLA_GBRCOND Estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number  cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function dla_gbrcond(TRANS, N, KL, KU, AB, LDAB, AFB, LDAFB,
                                      IPIV, CMODE, C, INFO, WORK, IWORK)
```

C specification:

```
#include "armpl.h"

double dla_gbrcond_(const char *trans, const armpl_int_t *n,
                    const armpl_int_t *kl, const armpl_int_t *ku,
                    const double *ab, const armpl_int_t *ldab,
                    const double *afb, const armpl_int_t *ldafb,
```

(continues on next page)

(continued from previous page)

```
                    const armpl_int_t *ipiv, const armpl_int_t *cmode,
                    const double *c, armpl_int_t *info, double *work,
                    armpl_int_t *iwork, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is DOUBLE PRECISION

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by DGBTRF; row i of the matrix was interchanged with row IPIV(i).

CMODE Input parameter.

CMODE is INTEGER

Determines op2(C) in the formula op(A) * op2(C) as follows: CMODE = 1 op2(C) = C CMODE = 0 op2(C) = I CMODE = -1 op2(C) = inv(C)

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The vector C in the formula op(A) * op2(C).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (5*N).. Workspace.

IWORK Input parameter.

IWORK is INTEGER array, dimension (N).

Workspace.

4.17.208 dla_gbrfsx_extended

dla_gbrfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by DGBRFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine dla_gbrfsx_extended(PREC_TYPE, TRANS_TYPE, N, KL, KU, NRHS, AB,
                               LDAB, AFB, LDAFB, IPIV, COLEQU, C, B, LDB, Y,
                               LDY, BERR_OUT, N_NORMS, ERR_BNDS_NORM,
                               ERR_BNDS_COMP, RES, AYB, DY, Y_TAIL, RCOND,
                               ITHRESH, RTHRESH, DZ_UB, IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void dla_gbrfsx_extended_(const armpl_int_t *prec_type,
                          const armpl_int_t *trans_type, const armpl_int_t *n,
                          const armpl_int_t *kl, const armpl_int_t *ku,
                          const armpl_int_t *nrhs, const double *ab,
                          const armpl_int_t *ldab, const double *afb,
                          const armpl_int_t *ldafb, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const double *c,
```

(continues on next page)

(continued from previous page)

```
                                const double *b, const armpl_int_t *ldb, double *y,
                                const armpl_int_t *ldy, double *berr_out,
                                const armpl_int_t *n_norms, double *err_bnds_norm,
                                double *err_bnds_comp, double *res, double *ayb,
                                double *dy, double *y_tail, const double *rcond,
                                const armpl_int_t *ithresh, const double *rthresh,
                                const double *dz_ub,
                                const armpl_int_t *ignore_cwise,
                                armpl_int_t *info);
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

TRANS_TYPE Input parameter.

TRANS_TYPE is INTEGER

Specifies the transposition operation on A. The value is defined by ILATRANS(T) where T is a CHARACTER and T = 'N': No transpose = 'T': Transpose = 'C': Conjugate transpose

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the N-by-N matrix AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDBA >= max(1, N).

AFB Input parameter.

AFB is DOUBLE PRECISION

AFB is an array, dimension (LDAFB, N). The factors L and U from the factorization A = P*L*U as computed by DGBTRF.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AF. LDAFB >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by DGBTRF; row i of the matrix was interchanged with row IPIV(i).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by DGBTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is DOUBLE PRECISION

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by DLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is DOUBLE PRECISION

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N). Workspace. This can be the same workspace passed for Y_TAIL.

DY Input parameter.

DY is DOUBLE PRECISION

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is DOUBLE PRECISION

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is DOUBLE PRECISION

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is DOUBLE PRECISION

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to DGBTRS had an illegal value

Related Information

For this routine in other precisions, please see *cla_gbrfsx_extended*, *sla_gbrfsx_extended* and *zla_gbrfsx_extended*.

4.17.209 dla_gbrpvgrw

DLA_GBRPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

double precision function dla_gbrpvgrw(N, KL, KU, NCOLS, AB, LDAB, AFB,
                                       LDAFB)
```

C specification:

```
#include "armpl.h"

double dla_gbrpvgrw_(const armpl_int_t *n, const armpl_int_t *kl,
                     const armpl_int_t *ku, const armpl_int_t *ncols,
                     const double *ab, const armpl_int_t *ldab,
                     const double *afb, const armpl_int_t *ldafb);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is DOUBLE PRECISION

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

Related Information

For this routine in other precisions, please see *cla_gbrpvgrw*, *sla_gbrpvgrw* and *zla_gbrpvgrw*.

4.17.210 dla_geamv

DLA_GEAMV performs one of the matrix-vector operations

```
     y := alpha*abs(A)*abs(x) + beta*abs(y),
or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine dla_geamv(TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void dla_geamv_(const armpl_int_t *trans, const armpl_int_t *m,
                const armpl_int_t *n, const double *alpha, const double *a,
                const armpl_int_t *lda, const double *x,
                const armpl_int_t *incx, const double *beta, double *y,
                const armpl_int_t *incy);
```

Parameters

TRANS Input parameter.

TRANS is INTEGER

On entry, TRANS specifies the operation to be performed as follows:

BLAS_NO_TRANS y := alpha*abs(A)*abs(x) + beta*abs(y) BLAS_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y) BLAS_CONJ_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y)

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, n). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m). Unchanged on exit.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array,. dimension at least (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Level 2 Blas routine.

Related Information

For this routine in other precisions, please see *cla_geamv*, *sla_geamv* and *zla_geamv*.

4.17.211 dla_gercond

```
DLA_GERCOND estimates the Skeel condition number of op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function dla_gercond(TRANS, N, A, LDA, AF, LDAF, IPIV, CMODE,
                                      C, INFO, WORK, IWORK)
```

C specification:

```
#include "armpl.h"

double dla_gercond_(const char *trans, const armpl_int_t *n, const double *a,
                    const armpl_int_t *lda, const double *af,
                    const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                    const armpl_int_t *cmode, const double *c,
                    armpl_int_t *info, double *work, armpl_int_t *iwork,
                    ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by DGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by DGETRF; row i of the matrix was interchanged with row IPIV(i).

CMODE Input parameter.

CMODE is INTEGER

Determines op2(C) in the formula op(A) * op2(C) as follows: CMODE = 1 op2(C) = C CMODE = 0 op2(C) = I CMODE = -1 op2(C) = inv(C)

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The vector C in the formula op(A) * op2(C).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N).. Workspace.

IWORK Input parameter.

IWORK is INTEGER array, dimension (N).

Workspace.

Related Information

4.17.212 dla_gerfsx_extended

`dla_gerfsx_extended` improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by DGERFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERRS_N and ERRS_C for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERRS_N and ERRS_C.

Syntax

Fortran specification:

```
use armpl_library

subroutine dla_gerfsx_extended(PREC_TYPE, TRANS_TYPE, N, NRHS, A, LDA, AF,
                               LDAF, IPIV, COLEQU, C, B, LDB, Y, LDY,
                               BERR_OUT, N_NORMS, ERRS_N, ERRS_C, RES, AYB,
                               DY, Y_TAIL, RCOND, ITHRESH, RTHRESH, DZ_UB,
                               IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void dla_gerfsx_extended_(const armpl_int_t *prec_type,
                          const armpl_int_t *trans_type, const armpl_int_t *n,
                          const armpl_int_t *nrhs, const double *a,
                          const armpl_int_t *lda, const double *af,
                          const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const double *c,
                          const double *b, const armpl_int_t *ldb, double *y,
                          const armpl_int_t *ldy, double *berr_out,
                          const armpl_int_t *n_norms, double *errs_n,
                          double *errs_c, double *res, double *ayb,
                          double *dy, double *y_tail, const double *rcond,
                          const armpl_int_t *ithresh, const double *rthresh,
                          const double *dz_ub,
                          const armpl_int_t *ignore_cwise,
                          armpl_int_t *info);
```

Parameters

PREC_TYPE Input parameter.

`PREC_TYPE` is `INTEGER`

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

TRANS_TYPE Input parameter.

`TRANS_TYPE` is `INTEGER`

Specifies the transposition operation on `A`. The value is defined by ILATRANS(T) where T is a CHARACTER and T = '`N`': No transpose = '`T`': Transpose = '`C`': Conjugate transpose

N Input parameter.

`N` is `INTEGER`

The number of linear equations, i.e., the order of the matrix `A`. `N` >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by DGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by DGETRF; row i of the matrix was interchanged with row IPIV(i).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by DGETRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is DOUBLE PRECISION

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by DLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERRS_N and ERRS_C). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERRS_N Input and output parameter.

ERRS_N is DOUBLE PRECISION

ERRS_N is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERRS_N(i,:) corresponds to the ith right-hand side.

The second index in ERRS_N(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERRS_C Input and output parameter.

ERRS_C is DOUBLE PRECISION

ERRS_C is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERRS_C is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERRS_C(i,:) corresponds to the ith right-hand side.

The second index in ERRS_C(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is DOUBLE PRECISION

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N). Workspace. This can be the same workspace passed for Y_TAIL.

DY Input parameter.

DY is DOUBLE PRECISION

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is DOUBLE PRECISION

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For ‘aggressive’ set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERRS_N and ERRS_C may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is DOUBLE PRECISION

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For ‘aggressive’ set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is DOUBLE PRECISION

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution `Y` is stable, which we definte as the relative change in each component being less than `DZ_UB`. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

`IGNORE_CWISE` is `LOGICAL`

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

`INFO` is `INTEGER`

= 0: Successful exit. < 0: if `INFO` = -i, the ith argument to DGETRS had an illegal value

Related Information

For this routine in other precisions, please see *cla_gerfsx_extended*, *sla_gerfsx_extended* and *zla_gerfsx_extended*.

4.17.213 dla_gerpvgrw

DLA_GERPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

double precision function dla_gerpvgrw(N, NCOLS, A, LDA, AF, LDAF)
```

C specification:

```
#include "armpl.h"

double dla_gerpvgrw_(const armpl_int_t *n, const armpl_int_t *ncols,
                     const double *a, const armpl_int_t *lda,
                     const double *af, const armpl_int_t *ldaf);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The number of linear equations, i.e., the order of the matrix `A`. `N` >= 0.

NCOLS Input parameter.

`NCOLS` is `INTEGER`

The number of columns of the matrix `A`. `NCOLS` >= 0.

A Input parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). On entry, the N-by-N matrix `A`.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by DGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

Related Information

For this routine in other precisions, please see *cla_gerpvgrw*, *sla_gerpvgrw* and *zla_gerpvgrw*.

4.17.214 dla_lin_berr

```
DLA_LIN_BERR computes component-wise relative backward error from
   the formula
       max(i) ( abs(R(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
   where abs(Z) is the component-wise absolute value of the matrix
   or vector Z.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dla_lin_berr(N, NZ, NRHS, RES, AYB, BERR)
```

C specification:

```
#include "armpl.h"

void dla_lin_berr_(const armpl_int_t *n, const armpl_int_t *nz,
                   const armpl_int_t *nrhs, const double *res,
                   const double *ayb, double *berr);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NZ Input parameter.

NZ is INTEGER

We add (NZ+1)*SLAMCH('Safe minimum') to R(i) in the numerator to guard against spuriously zero residuals. Default value is N.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices AYB, RES, and BERR. NRHS >= 0.

RES Input parameter.

RES is DOUBLE PRECISION

RES is an array, dimension (N, NRHS). The residual matrix, i.e., the matrix R in the relative backward error formula above.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N, NRHS). The denominator in the relative backward error formula above, i.e., the matrix abs(op(A_s))*abs(Y) + abs(B_s). The matrices A, Y, and B are from iterative refinement (see dla_gerfsx_extended.f).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The component-wise relative backward error from the formula above.

Related Information

For this routine in other precisions, please see *cla_lin_berr*, *sla_lin_berr* and *zla_lin_berr*.

4.17.215 dla_porcond

```
DLA_PORCOND Estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number  cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function dla_porcond(UPLO, N, A, LDA, AF, LDAF, CMODE, C,
                                      INFO, WORK, IWORK)
```

C specification:

```
#include "armpl.h"

double dla_porcond_(const char *uplo, const armpl_int_t *n, const double *a,
                    const armpl_int_t *lda, const double *af,
                    const armpl_int_t *ldaf, const armpl_int_t *cmode,
                    const double *c, armpl_int_t *info, double *work,
                    armpl_int_t *iwork, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by DPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

CMODE Input parameter.

CMODE is INTEGER

Determines op2(C) in the formula op(A) * op2(C) as follows: CMODE = 1 op2(C) = C CMODE = 0 op2(C) = I CMODE = -1 op2(C) = inv(C)

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The vector C in the formula op(A) * op2(C).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N).. Workspace.

IWORK Input parameter.

IWORK is INTEGER array, dimension (N).

Workspace.

                          double *dy, double *y_tail, const double *rcond,
                          const armpl_int_t *ithresh, const double *rthresh,
                          const double *dz_ub,
                          const armpl_int_t *ignore_cwise, armpl_int_t *info,
                          ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by DPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by DPOTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is DOUBLE PRECISION

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s)

)(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by DLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is DOUBLE PRECISION

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N). Workspace. This can be the same workspace passed for Y_TAIL.

DY Input parameter.

DY is DOUBLE PRECISION

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is DOUBLE PRECISION

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is DOUBLE PRECISION

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is DOUBLE PRECISION

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to DPOTRS had an illegal value

Related Information

4.17.217 dla_porpvgrw

DLA_PORPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

double precision function dla_porpvgrw(UPLO, NCOLS, A, LDA, AF, LDAF, WORK)
```

C specification:

```
#include "armpl.h"

double dla_porpvgrw_(const char *uplo, const armpl_int_t *ncols,
                     const double *a, const armpl_int_t *lda,
                     const double *af, const armpl_int_t *ldaf, double *work,
                     ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA,N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1,N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF,N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by DPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1,N).

WORK Input parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *cla_porpvgrw*, *sla_porpvgrw* and *zla_porpvgrw*.

4.17.218 dla_syamv

DLA_SYAMV performs the matrix-vector operation

```
y := alpha*abs(A)*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an n by n symmetric matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine dla_syamv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void dla_syamv_(const armpl_int_t *uplo, const armpl_int_t *n,
                const double *alpha, const double *a, const armpl_int_t *lda,
                const double *x, const armpl_int_t *incx, const double *beta,
                double *y, const armpl_int_t *incy);
```

Parameters

UPLO Input parameter.

UPLO is INTEGER

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = BLAS_UPPER Only the upper triangular part of A is to be referenced.

UPLO = BLAS_LOWER Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION .

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, n).. Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n). Unchanged on exit.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension. (1 + (n - 1)*abs(INCX)) Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION .

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension. (1 + (n - 1)*abs(INCY)) Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Related Information

For this routine in other precisions, please see *cla_syamv*, *sla_syamv* and *zla_syamv*.

4.17.219 dla_syrcond

```
DLA_SYRCOND estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function dla_syrcond(UPLO, N, A, LDA, AF, LDAF, IPIV, CMODE,
                                      C, INFO, WORK, IWORK)
```

C specification:

```
#include "armpl.h"

double dla_syrcond_(const char *uplo, const armpl_int_t *n, const double *a,
                    const armpl_int_t *lda, const double *af,
                    const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                    const armpl_int_t *cmode, const double *c,
                    armpl_int_t *info, double *work, armpl_int_t *iwork,
                    ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

CMODE Input parameter.

CMODE is INTEGER

Determines op2(C) in the formula op(A) * op2(C) as follows: CMODE = 1 op2(C) = C CMODE = 0 op2(C) = I CMODE = -1 op2(C) = inv(C)

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The vector C in the formula op(A) * op2(C).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N).. Workspace.

IWORK Input parameter.

IWORK is INTEGER array, dimension (N).

Workspace.

4.17.220 dla_syrfsx_extended

dla_syrfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by DSYRFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine dla_syrfsx_extended(PREC_TYPE, UPLO, N, NRHS, A, LDA, AF, LDAF,
                               IPIV, COLEQU, C, B, LDB, Y, LDY, BERR_OUT,
                               N_NORMS, ERR_BNDS_NORM, ERR_BNDS_COMP, RES,
```

(continues on next page)

(continued from previous page)

```
                                AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
                                DZ_UB, IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void dla_syrfsx_extended_(const armpl_int_t *prec_type, const char *uplo,
                          const armpl_int_t *n, const armpl_int_t *nrhs,
                          const double *a, const armpl_int_t *lda,
                          const double *af, const armpl_int_t *ldaf,
                          const armpl_int_t *ipiv, const armpl_int_t *colequ,
                          const double *c, const double *b,
                          const armpl_int_t *ldb, double *y,
                          const armpl_int_t *ldy, double *berr_out,
                          const armpl_int_t *n_norms, double *err_bnds_norm,
                          double *err_bnds_comp, double *res, double *ayb,
                          double *dy, double *y_tail, const double *rcond,
                          const armpl_int_t *ithresh, const double *rthresh,
                          const double *dz_ub,
                          const armpl_int_t *ignore_cwise, armpl_int_t *info,
                          ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by DSYTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is DOUBLE PRECISION

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by DLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is DOUBLE PRECISION

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N). Workspace. This can be the same workspace passed for Y_TAIL.

DY Input parameter.

DY is DOUBLE PRECISION

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is DOUBLE PRECISION

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is DOUBLE PRECISION

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is DOUBLE PRECISION

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to DLA_SYRFSX_EXTENDED had an illegal value

4.17.221 dla_syrpvgrw

DLA_SYRPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

double precision function dla_syrpvgrw(UPLO, N, INFO, A, LDA, AF, LDAF, IPIV,
                                       WORK)
```

C specification:

```
#include "armpl.h"

double dla_syrpvgrw_(const char *uplo, const armpl_int_t *n,
                     const armpl_int_t *info, const double *a,
                     const armpl_int_t *lda, const double *af,
                     const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                     double *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

INFO Input parameter.

INFO is INTEGER

The value of INFO returned from DSYTRF, .i.e., the pivot in column INFO is exactly 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is DOUBLE PRECISION

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

WORK Input parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *cla_syrpvgrw*, *sla_syrpvgrw* and *zla_syrpvgrw*.

4.17.222 dla_wwaddw

```
DLA_WWADDW adds a vector W into a doubled-single vector (X, Y).

   This works for all extant IBM's hex and binary floating point
   arithmetics, but not for decimal.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dla_wwaddw(N, X, Y, W)
```

C specification:

```
#include "armpl.h"

void dla_wwaddw_(const armpl_int_t *n, double *x, double *y,
                 const double *w);
```

Parameters

N Input parameter.

N is INTEGER

The length of vectors X, Y, and W.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). The first part of the doubled-single accumulation vector.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (N). The second part of the doubled-single accumulation vector.

W Input parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The vector to be added.

Related Information

For this routine in other precisions, please see *cla_wwaddw*, *sla_wwaddw* and *zla_wwaddw*.

4.17.223 dlabrd

dlabrd reduces the first NB rows and columns of a real general m by n matrix A to upper or lower bidiagonal form by an orthogonal transformation Q^T * A * P, and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A.

If m >= n, A is reduced to upper bidiagonal form; if m < n, to lower bidiagonal form.

This is an auxiliary routine called by DGEBRD

Syntax

Fortran specification:

```
use armpl_library

subroutine dlabrd(M, N, NB, A, LDA, D, E, TAUQ, TAUP, X, LDX, Y, LDY)
```

C specification:

```
#include "armpl.h"

void dlabrd_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nb, double *a, const armpl_int_t *lda,
             double *d, double *e, double *tauq, double *taup, double *x,
             const armpl_int_t *ldx, double *y, const armpl_int_t *ldy);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A.

N Input parameter.

N is INTEGER

The number of columns in the matrix A.

NB Input parameter.

NB is INTEGER

The number of leading rows and columns of A to be reduced.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the m by n general matrix to be reduced. On exit, the first NB rows and columns of the matrix are overwritten; the rest of the array is unchanged. If m >= n, elements on and below the diagonal in the first NB columns, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors; and elements above the diagonal in the first NB rows, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. If m < n, elements below the diagonal in the first NB columns, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first NB rows, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (NB). The diagonal elements of the first NB rows and columns of the reduced matrix. D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (NB). The off-diagonal elements of the first NB rows and columns of the reduced matrix.

TAUQ Output parameter.

TAUQ is DOUBLE PRECISION

TAUQ is an array, dimension (NB). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

TAUP Output parameter.

TAUP is DOUBLE PRECISION

TAUP is an array, dimension (NB). The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NB). The m-by-nb matrix X required to update the unreduced part of A.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, M).

Y Output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (LDY, NB). The n-by-nb matrix Y required to update the unreduced part of A.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

Related Information

For this routine in other precisions, please see *clabrd*, *slabrd* and *zlabrd*.

4.17.224 dlacn2

dlacn2 estimates the 1-norm of a square, real matrix A. Reverse communication is used for evaluating matrix-vector products.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlacn2(N, V, X, ISGN, EST, KASE, ISAVE)
```

C specification:

```
#include "armpl.h"

void dlacn2_(const armpl_int_t *n, double *v, double *x, armpl_int_t *isgn,
             double *est, armpl_int_t *kase, armpl_int_t *isave);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 1.

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension (N). On the final return, V = A*W, where EST = norm(V)/norm(W) (W is not returned).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). On an intermediate return, X should be overwritten by A * X, if KASE=1, A^T * X, if KASE=2, and DLACN2 must be re-called with all the other parameters unchanged.

ISGN Output parameter.

ISGN is INTEGER array, dimension (N)

EST Input and output parameter.

EST is DOUBLE PRECISION

On entry with KASE = 1 or 2 and ISAVE(1) = 3, EST should be unchanged from the previous call to DLACN2. On exit, EST is an estimate (a lower bound) for norm(A).

KASE Input and output parameter.

KASE is INTEGER

On the initial call to DLACN2, KASE should be 0. On an intermediate return, KASE will be 1 or 2, indicating whether X should be overwritten by A * X or A^T * X. On the final return from DLACN2, KASE will again be 0.

ISAVE Input and output parameter.

ISAVE is INTEGER array, dimension (3)

ISAVE is used to save variables between calls to DLACN2

Related Information

For this routine in other precisions, please see *clacn2*, *slacn2* and *zlacn2*. It also exists with a native C interface as *LAPACKE_dlacn2*.

4.17.225 dlacon

dlacon estimates the 1-norm of a square, real matrix A. Reverse communication is used for evaluating matrix-vector products.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlacon(N, V, X, ISGN, EST, KASE)
```

C specification:

```
#include "armpl.h"

void dlacon_(const armpl_int_t *n, double *v, double *x, armpl_int_t *isgn,
             double *est, armpl_int_t *kase);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 1.

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension (N). On the final return, V = A*W, where EST = norm(V)/norm(W) (W is not returned).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). On an intermediate return, X should be overwritten by A * X, if KASE=1, A^T * X, if KASE=2, and DLACON must be re-called with all the other parameters unchanged.

ISGN Output parameter.

ISGN is INTEGER array, dimension (N)

EST Input and output parameter.

EST is DOUBLE PRECISION

On entry with KASE = 1 or 2 and JUMP = 3, EST should be unchanged from the previous call to DLACON. On exit, EST is an estimate (a lower bound) for norm(A).

KASE Input and output parameter.

KASE is INTEGER

On the initial call to DLACON, KASE should be 0. On an intermediate return, KASE will be 1 or 2, indicating whether X should be overwritten by A * X or A^T * X. On the final return from DLACON, KASE will again be 0.

Related Information

For this routine in other precisions, please see *clacon*, *slacon* and *zlacon*.

4.17.226 dlacpy

dlacpy copies all or part of a two-dimensional matrix A to another matrix B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlacpy(UPLO, M, N, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void dlacpy_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const double *a, const armpl_int_t *lda, double *b,
             const armpl_int_t *ldb, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be copied to B. = 'U': Upper triangular part = 'L': Lower triangular part Otherwise: All of the matrix A

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The m by n matrix A. If UPLO = 'U', only the upper triangle or trapezoid is accessed; if UPLO = 'L', only the lower triangle or trapezoid is accessed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On exit, B = A in the locations specified by UPLO.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

Related Information

For this routine in other precisions, please see *clacpy*, *slacpy* and *zlacpy*. It also exists with a native C interface as *LAPACKE_dlacpy*.

4.17.227 dladiv

dladiv performs complex division in real arithmetic

```
            a + i*b
p + i*q = ---------
            c + i*d
```

The algorithm is due to Michael Baudin and Robert L. Smith and can be found in the paper "A Robust Complex Division in Scilab"

Syntax

Fortran specification:

```
use armpl_library

subroutine dladiv(A, B, C, D, P, Q)
```

C specification:

```
#include "armpl.h"

void dladiv_(const double *a, const double *b, const double *c,
             const double *d, double *p, double *q);
```

Parameters

A Input parameter.

A is DOUBLE PRECISION

B Input parameter.

B is DOUBLE PRECISION

C Input parameter.

C is DOUBLE PRECISION

D Input parameter.

D is DOUBLE PRECISION

The scalars a, b, c, and d in the above expression.

P Output parameter.

P is DOUBLE PRECISION

Q Output parameter.

Q is DOUBLE PRECISION

The scalars p and q in the above expression.

Related Information

For this routine in other precisions, please see *cladiv*, *sladiv* and *zladiv*.

4.17.228 dlae2

dlae2 computes the eigenvalues of a 2-by-2 symmetric matrix

```
[  A   B  ]
[  B   C  ].
```

On return, RT1 is the eigenvalue of larger absolute value, and RT2 is the eigenvalue of smaller absolute value.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlae2(A, B, C, RT1, RT2)
```

C specification:

```
#include "armpl.h"

void dlae2_(const double *a, const double *b, const double *c, double *rt1,
            double *rt2);
```

Parameters

A Input parameter.

A is DOUBLE PRECISION

The (1,1) element of the 2-by-2 matrix.

B Input parameter.

B is DOUBLE PRECISION

The (1,2) and (2,1) elements of the 2-by-2 matrix.

C Input parameter.

C is DOUBLE PRECISION

The (2,2) element of the 2-by-2 matrix.

RT1 Output parameter.

RT1 is DOUBLE PRECISION

The eigenvalue of larger absolute value.

RT2 Output parameter.

RT2 is DOUBLE PRECISION

The eigenvalue of smaller absolute value.

Related Information

For this routine in other precisions, please see *slae2*.

4.17.229 dlaebz

dlaebz contains the iteration loops which compute and use the function N(w), which is the count of eigenvalues of a symmetric tridiagonal matrix T less than or equal to its argument w. It performs a choice of two types of loops:

IJOB=1, followed by IJOB=2: It takes as input a list of intervals and returns a list of

```
sufficiently small intervals whose union contains the same
eigenvalues as the union of the original intervals.
The input intervals are (AB(j,1),AB(j,2)], j=1,...,MINP.
The output interval (AB(j,1),AB(j,2)] will contain
eigenvalues NAB(j,1)+1,...,NAB(j,2), where 1 <= j <= MOUT.
```

IJOB=3: It performs a binary search in each input interval

```
(AB(j,1),AB(j,2)] for a point  w(j)  such that
N(w(j))=NVAL(j), and uses  C(j)  as the starting point of
the search.  If such a w(j) is found, then on output
AB(j,1)=AB(j,2)=w.  If no such w(j) is found, then on output
(AB(j,1),AB(j,2)] will be a small interval containing the
point where N(w) jumps through NVAL(j), unless that point
lies outside the initial interval.
```

Note that the intervals are in all cases half-open intervals, i.e., of the form (a,b] , which includes b but not a .

To avoid underflow, the matrix should be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value. To assure the most accurate computation of small eigenvalues, the matrix should be scaled to be not much smaller than that, either.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966

Note: the arguments are, in general, *not* checked for unreasonable values.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaebz(IJOB, NITMAX, N, MMAX, MINP, NBMIN, ABSTOL, RELTOL, PIVMIN,
                  D, E, E2, NVAL, AB, C, MOUT, NAB, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlaebz_(const armpl_int_t *ijob, const armpl_int_t *nitmax,
             const armpl_int_t *n, const armpl_int_t *mmax,
             const armpl_int_t *minp, const armpl_int_t *nbmin,
             const double *abstol, const double *reltol, const double *pivmin,
             const double *d, const double *e, const double *e2,
             armpl_int_t *nval, double *ab, double *c, armpl_int_t *mout,
             armpl_int_t *nab, double *work, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

IJOB Input parameter.

IJOB is INTEGER

Specifies what is to be done: = 1: Compute NAB for the initial intervals. = 2: Perform bisection iteration to find eigenvalues of T. = 3: Perform bisection iteration to invert N(w), i.e., to find a point which has a specified number of eigenvalues of T to its left. Other values will cause DLAEBZ to return with INFO=-1.

NITMAX Input parameter.

NITMAX is INTEGER

The maximum number of "levels" of bisection to be performed, i.e., an interval of width W will not be made smaller than 2^(-NITMAX) * W. If not all intervals have converged after NITMAX iterations, then INFO is set to the number of non-converged intervals.

N Input parameter.

N is INTEGER

The dimension n of the tridiagonal matrix T. It must be at least 1.

MMAX Input parameter.

MMAX is INTEGER

The maximum number of intervals. If more than MMAX intervals are generated, then DLAEBZ will quit with INFO=MMAX+1.

MINP Input parameter.

MINP is INTEGER

The initial number of intervals. It may not be greater than MMAX.

NBMIN Input parameter.

NBMIN is INTEGER

The smallest number of intervals that should be processed using a vector loop. If zero, then only the scalar loop will be used.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The minimum (absolute) width of an interval. When an interval is narrower than ABSTOL, or than RELTOL times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. This must be at least zero.

RELTOL Input parameter.

RELTOL is DOUBLE PRECISION

The minimum relative width of an interval. When an interval is narrower than ABSTOL, or than RELTOL times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum absolute value of a "pivot" in the Sturm sequence loop. This must be at least max |e(j)**2|*safe_min and at least safe_min, where safe_min is at least the smallest number that can divide one without overflow.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). The offdiagonal elements of the tridiagonal matrix T in positions 1 through N-1. E(N) is arbitrary.

E2 Input parameter.

E2 is DOUBLE PRECISION

E2 is an array, dimension (N). The squares of the offdiagonal elements of the tridiagonal matrix T. E2(N) is ignored.

NVAL Input and output parameter.

NVAL is INTEGER array, dimension (MINP)

If IJOB=1 or 2, not referenced. If IJOB=3, the desired values of N(w). The elements of NVAL will be reordered to correspond with the intervals in AB. Thus, NVAL(j) on output will not, in general be the same as NVAL(j) on input, but it will correspond with the interval (AB(j,1),AB(j,2)] on output.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (MMAX,2). The endpoints of the intervals. AB(j,1) is a(j), the left endpoint of the j-th interval, and AB(j,2) is b(j), the right endpoint of the j-th interval. The input intervals will, in general, be modified, split, and reordered by the calculation.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (MMAX). If IJOB=1, ignored. If IJOB=2, workspace. If IJOB=3, then on input C(j) should be initialized to the first search point in the binary search.

MOUT Output parameter.

MOUT is INTEGER

If IJOB=1, the number of eigenvalues in the intervals. If IJOB=2 or 3, the number of intervals output. If IJOB=3, MOUT will equal MINP.

NAB Input and output parameter.

NAB is INTEGER array, dimension (MMAX,2)

If IJOB=1, then on output NAB(i,j) will be set to N(AB(i,j)). If IJOB=2, then on input, NAB(i,j) should be set. It must satisfy the condition: N(AB(i,1)) <= NAB(i,1) <= NAB(i,2) <= N(AB(i,2)), which means that in interval i only eigenvalues NAB(i,1)+1,...,NAB(i,2) will be considered. Usually, NAB(i,j)=N(AB(i,j)), from a previous call to DLAEBZ with IJOB=1. On output, NAB(i,j) will contain max(na(k),min(nb(k),N(AB(i,j)))), where k is the index of the input interval that the output interval (AB(j,1),AB(j,2)] came from, and na(k) and nb(k) are the the input values of NAB(k,1) and NAB(k,2). If IJOB=3, then on output, NAB(i,j) contains N(AB(i,j)), unless N(w) > NVAL(i) for all search points w , in which case NAB(i,1) will not be modified, i.e., the output value will be the same as the input value (modulo reorderings – see NVAL and AB), or unless N(w) < NVAL(i) for all search points w , in which case NAB(i,2) will not be modified. Normally, NAB should be set to some distinctive value(s) before DLAEBZ is called.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MMAX). Workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MMAX)

Workspace.

INFO Output parameter.

INFO is INTEGER

= 0: All intervals converged. = 1–MMAX: The last INFO intervals did not converge. = MMAX+1: More than MMAX intervals were generated.

Related Information

For this routine in other precisions, please see *slaebz*.

4.17.230 dlaed0

dlaed0 computes all eigenvalues and corresponding eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed0(ICOMPQ, QSIZ, N, D, E, Q, LDQ, QSTORE, LDQS, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dlaed0_(const armpl_int_t *icompq, const armpl_int_t *qsiz,
             const armpl_int_t *n, double *d, const double *e, double *q,
             const armpl_int_t *ldq, double *qstore, const armpl_int_t *ldqs,
             double *work, armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

= 0: Compute eigenvalues only. = 1: Compute eigenvectors of original dense symmetric matrix also. On entry, Q contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 2: Compute eigenvalues and eigenvectors of tridiagonal matrix.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the orthogonal matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the main diagonal of the tridiagonal matrix. On exit, its eigenvalues.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, Q must contain an N-by-N orthogonal matrix. If ICOMPQ = 0 Q is not referenced. If ICOMPQ = 1 On entry, Q is a subset of the columns of the orthogonal matrix used to reduce the full matrix to tridiagonal form corresponding to the subset of the full matrix which is being decomposed at this time. If ICOMPQ = 2 On entry, Q will be the identity matrix. On exit, Q contains the eigenvectors of the tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If eigenvectors are desired, then LDQ >= max(1, N). In any case, LDQ >= 1.

QSTORE Output parameter.

QSTORE is DOUBLE PRECISION

QSTORE is an array, dimension (LDQS, N). Referenced only when ICOMPQ = 1. Used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

LDQS Input parameter.

LDQS is INTEGER

The leading dimension of the array QSTORE. If ICOMPQ = 1, then LDQS >= max(1, N). In any case, LDQS >= 1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array,. If ICOMPQ = 0 or 1, the dimension of WORK must be at least 1 + 3* N + 2*N*lg N + 3*N**2 (lg(N) = smallest integer k such that 2^k >= N) If ICOMPQ = 2, the dimension of WORK must be at least 4* N + N**2.

IWORK Output parameter.

IWORK is INTEGER array,

If ICOMPQ = 0 or 1, the dimension of IWORK must be at least 6 + 6* N + 5*N*lg N. (lg(N) = smallest integer k such that 2^k >= N) If ICOMPQ = 2, the dimension of IWORK must be at least 3 + 5*N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *claed0*, *slaed0* and *zlaed0*.

4.17.231 dlaed1

dlaed1 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and eigenvectors of a tridiagonal matrix. DLAED7 handles the case in which eigenvalues only or eigenvalues and eigenvectors of a full symmetric matrix (which was reduced to tridiagonal form) are desired.

```
T = Q(in) ( D(in) + RHO * Z*Z**T ) Q**T(in) = Q(out) * D(out) * Q**T(out)

where Z = Q**T*u, u is a vector of length N with ones in the
CUTPNT and CUTPNT + 1 th elements and zeros elsewhere.

The eigenvectors of the original matrix are stored in Q, and the
eigenvalues are in D.  The algorithm consists of three stages:

   The first stage consists of deflating the size of the problem
   when there are multiple eigenvalues or if there is a zero in
   the Z vector.  For each such occurrence the dimension of the
   secular equation problem is reduced by one.  This stage is
   performed by the routine DLAED2.

   The second stage consists of calculating the updated
   eigenvalues. This is done by finding the roots of the secular
   equation via the routine DLAED4 (as called by DLAED3).
   This routine also calculates the eigenvectors of the current
   problem.

   The final stage consists of computing the updated eigenvectors
   directly using the updated eigenvalues.  The eigenvectors for
   the current problem are multiplied with the eigenvectors from
   the overall problem.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed1(N, D, Q, LDQ, INDXQ, RHO, CUTPNT, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlaed1_(const armpl_int_t *n, double *d, double *q,
             const armpl_int_t *ldq, armpl_int_t *indxq, const double *rho,
             const armpl_int_t *cutpnt, double *work, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the eigenvalues of the rank-1-perturbed matrix. On exit, the eigenvalues of the repaired matrix.

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, the eigenvectors of the rank-1-perturbed matrix. On exit, the eigenvectors of the repaired tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

INDXQ Input and output parameter.

INDXQ is INTEGER array, dimension (N)

On entry, the permutation which separately sorts the two subproblems in D into ascending order. On exit, the permutation which will reintegrate the subproblems back into sorted order, i.e. D(INDXQ(I = 1, N)) will be in ascending order.

RHO Input parameter.

RHO is DOUBLE PRECISION

The subdiagonal entry used to create the rank-1 modification.

CUTPNT Input parameter.

CUTPNT is INTEGER

The location of the last eigenvalue in the leading sub-matrix. min(1, N) <= CUTPNT <= N/2.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4* N + N2)** .

IWORK Output parameter.

IWORK is INTEGER array, dimension (4*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *slaed1*.

4.17.232 dlaed2

dlaed2 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed2(K, N, N1, D, Q, LDQ, INDXQ, RHO, Z, DLAMDA, W, Q2, INDX,
                  INDXC, INDXP, COLTYP, INFO)
```

C specification:

```
#include "armpl.h"

void dlaed2_(armpl_int_t *k, const armpl_int_t *n, const armpl_int_t *n1,
             double *d, double *q, const armpl_int_t *ldq, armpl_int_t *indxq,
             double *rho, const double *z, double *dlamda, double *w,
             double *q2, armpl_int_t *indx, armpl_int_t *indxc,
             armpl_int_t *indxp, armpl_int_t *coltyp, armpl_int_t *info);
```

Parameters

K Output parameter.

K is INTEGER

The number of non-deflated eigenvalues, and the order of the related secular equation. 0 <= K <=N.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

N1 Input parameter.

N1 is INTEGER

The location of the last eigenvalue in the leading sub-matrix. min(1, N) <= N1 <= N/2.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, D contains the eigenvalues of the two submatrices to be combined. On exit, D contains the trailing (N-K) updated eigenvalues (those which were deflated) sorted into increasing order.

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, Q contains the eigenvectors of two submatrices in the two square blocks with corners at (1,1), (N1, N1) and (N1+1, N1+1), (N, N). On exit, Q contains the trailing (N-K) updated eigenvectors (those which were deflated) in its last N-K columns.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

INDXQ Input and output parameter.

INDXQ is INTEGER array, dimension (N)

The permutation which separately sorts the two sub-problems in D into ascending order. Note that elements in the second half of this permutation must first have N1 added to their values. Destroyed on exit.

RHO Input and output parameter.

RHO is DOUBLE PRECISION

On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined. On exit, RHO has been modified to the value required by DLAED3.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (N). On entry, Z contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). On exit, the contents of Z have been destroyed by the updating process.

DLAMDA Output parameter.

DLAMDA is DOUBLE PRECISION

DLAMDA is an array, dimension (N). A copy of the first K eigenvalues which will be used by DLAED3 to form the secular equation.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first k values of the final deflation-altered z-vector which will be passed to DLAED3.

Q2 Output parameter.

Q2 is DOUBLE PRECISION

Q2 is an array, dimension (N1**2+(N-N1)**2). A copy of the first K eigenvectors which will be used by DLAED3 in a matrix multiply (DGEMM) to solve for the new eigenvectors.

INDX Output parameter.

INDX is INTEGER array, dimension (N)

The permutation used to sort the contents of DLAMDA into ascending order.

INDXC Output parameter.

INDXC is INTEGER array, dimension (N)

The permutation used to arrange the columns of the deflated Q matrix into three groups: the first group contains non-zero elements only at and above N1, the second contains non-zero elements only below N1, and the third is dense.

INDXP Output parameter.

INDXP is INTEGER array, dimension (N)

The permutation used to place deflated values of D at the end of the array. INDXP(1:K) points to the nondeflated D-values and INDXP(K+1:N) points to the deflated eigenvalues.

COLTYP Output parameter.

COLTYP is INTEGER array, dimension (N)

During execution, a label which will indicate which of the following types a column in the Q2 matrix is: 1 : non-zero in the upper half only; 2 : dense; 3 : non-zero in the lower half only; 4 : deflated. On exit, COLTYP(i) is the number of columns of type i, for i=1 to 4 only.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *slaed2*.

4.17.233 dlaed3

dlaed3 finds the roots of the secular equation, as defined by the values in D, W, and RHO, between 1 and K. It makes the appropriate calls to DLAED4 and then updates the eigenvectors by multiplying the matrix of eigenvectors of the pair of eigensystems being combined by the matrix of eigenvectors of the K-by-K system which is solved here.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed3(K, N, N1, D, Q, LDQ, RHO, DLAMDA, Q2, INDX, CTOT, W, S,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dlaed3_(const armpl_int_t *k, const armpl_int_t *n,
             const armpl_int_t *n1, double *d, double *q,
             const armpl_int_t *ldq, const double *rho, double *dlamda,
             const double *q2, const armpl_int_t *indx,
             const armpl_int_t *ctot, double *w, double *s,
             armpl_int_t *info);
```

Parameters

K Input parameter.

K is INTEGER

The number of terms in the rational function to be solved by DLAED4. K >= 0.

N Input parameter.

N is INTEGER

The number of rows and columns in the Q matrix. N >= K (deflation may result in N>K).

N1 Input parameter.

N1 is INTEGER

The location of the last eigenvalue in the leading submatrix. min(1, N) <= N1 <= N/2.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). D(I) contains the updated eigenvalues for 1 <= I <= K.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). Initially the first K columns are used as workspace. On output the columns 1 to K contain the updated eigenvectors.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

RHO Input parameter.

RHO is DOUBLE PRECISION

The value of the parameter in the rank one update equation. RHO >= 0 required.

DLAMDA Input and output parameter.

DLAMDA is DOUBLE PRECISION

DLAMDA is an array, dimension (K). The first K elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation. May be changed on output by having lowest order bit set to zero on Cray X-MP, Cray Y-MP, Cray-2, or Cray C-90, as described above.

Q2 Input parameter.

Q2 is DOUBLE PRECISION

Q2 is an array, dimension (LDQ2*N). The first K columns of this matrix contain the non-deflated eigenvectors for the split problem.

INDX Input parameter.

INDX is INTEGER array, dimension (N)

The permutation used to arrange the columns of the deflated Q matrix into three groups (see DLAED2). The rows of the eigenvectors found by DLAED4 must be likewise permuted before the matrix multiply can take place.

CTOT Input parameter.

CTOT is INTEGER array, dimension (4)

A count of the total number of the various types of columns in Q, as described in INDX. The fourth column type is any column which has been deflated.

W Input and output parameter.

W is DOUBLE PRECISION

W is an array, dimension (K). The first K elements of this array contain the components of the deflation-adjusted updating vector. Destroyed on output.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N1 + 1)*K. Will contain the eigenvectors of the repaired matrix which will be multiplied by the previously accumulated eigenvectors to update the system.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *slaed3*.

4.17.234 dlaed4

This subroutine computes the I-th updated eigenvalue of a symmetric rank-one modification to a diagonal matrix whose elements are given in the array d, and that

```
D(i) < D(j)  for  i < j
```

and that RHO > 0. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

```
diag( D )  +  RHO * Z * Z_transpose.
```

where we assume the Euclidean norm of Z is 1.

The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed4(N, I, D, Z, DELTA, RHO, DLAM, INFO)
```

C specification:

```
#include "armpl.h"

void dlaed4_(const armpl_int_t *n, const armpl_int_t *i, const double *d,
             const double *z, double *delta, const double *rho, double *dlam,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The length of all arrays.

I Input parameter.

I is INTEGER

The index of the eigenvalue to be computed. 1 <= I <= N.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The original eigenvalues. It is assumed that they are in order, D(I) < D(J) for I < J.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (N). The components of the updating vector.

DELTA Output parameter.

DELTA is DOUBLE PRECISION

DELTA is an array, dimension (N). If N .GT. 2, DELTA contains (D(j) - lambda_I) in its j-th component. If N = 1, then DELTA(1) = 1. If N = 2, see DLAED5 for detail. The vector DELTA contains the information necessary to construct the eigenvectors by DLAED3 and DLAED9.

RHO Input parameter.

RHO is DOUBLE PRECISION

The scalar in the symmetric updating formula.

DLAM Output parameter.

DLAM is DOUBLE PRECISION

The computed lambda_I, the I-th updated eigenvalue.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = 1, the updating process failed.

Related Information

For this routine in other precisions, please see *slaed4*.

4.17.235 dlaed5

This subroutine computes the I-th eigenvalue of a symmetric rank-one modification of a 2-by-2 diagonal matrix

```
diag( D )  +  RHO * Z * transpose(Z) .
```

The diagonal elements in the array D are assumed to satisfy

```
D(i) < D(j)  for  i < j .
```

We also assume RHO > 0 and that the Euclidean norm of the vector Z is one.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed5(I, D, Z, DELTA, RHO, DLAM)
```

C specification:

```
#include "armpl.h"

void dlaed5_(const armpl_int_t *i, const double *d, const double *z,
             double *delta, const double *rho, double *dlam);
```

Parameters

I Input parameter.

I is INTEGER

The index of the eigenvalue to be computed. I = 1 or I = 2.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (2). The original eigenvalues. We assume D(1) < D(2).

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (2). The components of the updating vector.

DELTA Output parameter.

DELTA is DOUBLE PRECISION

DELTA is an array, dimension (2). The vector DELTA contains the information necessary to construct the eigenvectors.

RHO Input parameter.

RHO is DOUBLE PRECISION

The scalar in the symmetric updating formula.

DLAM Output parameter.

DLAM is DOUBLE PRECISION

The computed lambda_I, the I-th updated eigenvalue.

Related Information

For this routine in other precisions, please see *slaed5*.

4.17.236 dlaed6

dlaed6 computes the positive or negative root (closest to the origin) of

```
z(1)          z(2)          z(3)
```

f(x) = rho + ——— + ——— + ———

```
d(1)-x      d(2)-x      d(3)-x
```

It is assumed that

```
if ORGATI = .true. the root is between d(2) and d(3);
otherwise it is between d(1) and d(2)
```

This routine will be called by DLAED4 when necessary. In most cases, the root sought is the smallest in magnitude, though it might not be in some extremely rare situations.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed6(KNITER, ORGATI, RHO, D, Z, FINIT, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void dlaed6_(const armpl_int_t *kniter, const armpl_int_t *orgati,
             const double *rho, const double *d, const double *z,
             const double *finit, double *tau, armpl_int_t *info);
```

Parameters

KNITER Input parameter.

KNITER is INTEGER

Refer to DLAED4 for its significance.

ORGATI Input parameter.

ORGATI is LOGICAL

If ORGATI is true, the needed root is between d(2) and d(3); otherwise it is between d(1) and d(2). See DLAED4 for further details.

RHO Input parameter.

RHO is DOUBLE PRECISION

Refer to the equation f(x) above.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (3). D satisfies d(1) < d(2) < d(3).

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (3). Each of the elements in z must be positive.

FINIT Input parameter.

FINIT is DOUBLE PRECISION

The value of f at 0. It is more accurate than the one evaluated inside this routine (if someone wants to do so).

TAU Output parameter.

TAU is DOUBLE PRECISION

The root of the equation f(x).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = 1, failure to converge

Related Information

For this routine in other precisions, please see *slaed6*.

4.17.237 dlaed7

dlaed7 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and optionally eigenvectors of a dense symmetric matrix that has been reduced to tridiagonal form. DLAED1 handles the case in which all eigenvalues and eigenvectors of a symmetric tridiagonal matrix are desired.

```
T = Q(in) ( D(in) + RHO * Z*Z**T ) Q**T(in) = Q(out) * D(out) * Q**T(out)

where Z = Q**Tu, u is a vector of length N with ones in the
CUTPNT and CUTPNT + 1 th elements and zeros elsewhere.

The eigenvectors of the original matrix are stored in Q, and the
eigenvalues are in D.  The algorithm consists of three stages:

   The first stage consists of deflating the size of the problem
   when there are multiple eigenvalues or if there is a zero in
   the Z vector.  For each such occurrence the dimension of the
   secular equation problem is reduced by one.  This stage is
   performed by the routine DLAED8.

   The second stage consists of calculating the updated
   eigenvalues. This is done by finding the roots of the secular
   equation via the routine DLAED4 (as called by DLAED9).
   This routine also calculates the eigenvectors of the current
   problem.

   The final stage consists of computing the updated eigenvectors
   directly using the updated eigenvalues.  The eigenvectors for
   the current problem are multiplied with the eigenvectors from
   the overall problem.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed7(ICOMPQ, N, QSIZ, TLVLS, CURLVL, CURPBM, D, Q, LDQ, INDXQ,
                  RHO, CUTPNT, QSTORE, QPTR, PRMPTR, PERM, GIVPTR, GIVCOL,
                  GIVNUM, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlaed7_(const armpl_int_t *icompq, const armpl_int_t *n,
             const armpl_int_t *qsiz, const armpl_int_t *tlvls,
             const armpl_int_t *curlvl, const armpl_int_t *curpbm, double *d,
             double *q, const armpl_int_t *ldq, armpl_int_t *indxq,
             const double *rho, const armpl_int_t *cutpnt, double *qstore,
             armpl_int_t *qptr, const armpl_int_t *prmptr,
             const armpl_int_t *perm, const armpl_int_t *givptr,
             const armpl_int_t *givcol, const double *givnum, double *work,
             armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

= 0: Compute eigenvalues only. = 1: Compute eigenvectors of original dense symmetric matrix also. On entry, Q contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the orthogonal matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

TLVLS Input parameter.

TLVLS is INTEGER

The total number of merging levels in the overall divide and conquer tree.

CURLVL Input parameter.

CURLVL is INTEGER

The current level in the overall merge routine, 0 <= CURLVL <= TLVLS.

CURPBM Input parameter.

CURPBM is INTEGER

The current problem in the current level in the overall merge routine (counting from upper left to lower right).

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the eigenvalues of the rank-1-perturbed matrix. On exit, the eigenvalues of the repaired matrix.

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, the eigenvectors of the rank-1-perturbed matrix. On exit, the eigenvectors of the repaired tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

INDXQ Output parameter.

INDXQ is INTEGER array, dimension (N)

The permutation which will reintegrate the subproblem just solved back into sorted order, i.e., D(INDXQ(I = 1, N)) will be in ascending order.

RHO Input parameter.

RHO is DOUBLE PRECISION

The subdiagonal element used to create the rank-1 modification.

CUTPNT Input parameter.

CUTPNT is INTEGER

Contains the location of the last eigenvalue in the leading sub-matrix. min(1, N) <= CUTPNT <= N.

QSTORE Input and output parameter.

QSTORE is DOUBLE PRECISION

QSTORE is an array, dimension (N**2+1). Stores eigenvectors of submatrices encountered during divide and conquer, packed together. QPTR points to beginning of the submatrices.

QPTR Input and output parameter.

QPTR is INTEGER array, dimension (N+2)

List of indices pointing to beginning of submatrices stored in QSTORE. The submatrices are numbered starting at the bottom left of the divide and conquer tree, from left to right and bottom to top.

PRMPTR Input parameter.

PRMPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in PERM a level's permutation is stored. PRMPTR(i+1) - PRMPTR(i) indicates the size of the permutation and also the size of the full, non-deflated problem.

PERM Input parameter.

PERM is INTEGER array, dimension (N lg N)

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in GIVCOL a level's Givens rotations are stored. GIVPTR(i+1) - GIVPTR(i) indicates the number of Givens rotations.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (2, N lg N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Input parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (2, N lg N). Each number indicates the S value to be used in the corresponding Givens rotation.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N+2*QSIZ*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (4*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *claed7*, *slaed7* and *zlaed7*.

4.17.238 dlaed8

dlaed8 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny element in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed8(ICOMPQ, K, N, QSIZ, D, Q, LDQ, INDXQ, RHO, CUTPNT, Z,
                  DLAMDA, Q2, LDQ2, W, PERM, GIVPTR, GIVCOL, GIVNUM, INDXP,
                  INDX, INFO)
```

C specification:

```
#include "armpl.h"

void dlaed8_(const armpl_int_t *icompq, armpl_int_t *k, const armpl_int_t *n,
             const armpl_int_t *qsiz, double *d, double *q,
             const armpl_int_t *ldq, const armpl_int_t *indxq, double *rho,
             const armpl_int_t *cutpnt, const double *z, double *dlamda,
             double *q2, const armpl_int_t *ldq2, double *w,
             armpl_int_t *perm, armpl_int_t *givptr, armpl_int_t *givcol,
             double *givnum, armpl_int_t *indxp, armpl_int_t *indx,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

= 0: Compute eigenvalues only. = 1: Compute eigenvectors of original dense symmetric matrix also. On entry, Q contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

K Output parameter.

K is INTEGER

The number of non-deflated eigenvalues, and the order of the related secular equation.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the orthogonal matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the eigenvalues of the two submatrices to be combined. On exit, the trailing (N-K) updated eigenvalues (those which were deflated) sorted into increasing order.

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). If ICOMPQ = 0, Q is not referenced. Otherwise, on entry, Q contains the eigenvectors of the partially solved system which has been previously updated in matrix multiplies with other partially solved eigensystems. On exit, Q contains the trailing (N-K) updated eigenvectors (those which were deflated) in its last N-K columns.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

INDXQ Input parameter.

INDXQ is INTEGER array, dimension (N)

The permutation which separately sorts the two sub-problems in D into ascending order. Note that elements in the second half of this permutation must first have CUTPNT added to their values in order to be accurate.

RHO Input and output parameter.

RHO is DOUBLE PRECISION

On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined. On exit, RHO has been modified to the value required by DLAED3.

CUTPNT Input parameter.

CUTPNT is INTEGER

The location of the last eigenvalue in the leading sub-matrix. min(1, N) <= CUTPNT <= N.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (N). On entry, Z contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). On exit, the contents of Z are destroyed by the updating process.

DLAMDA Output parameter.

DLAMDA is DOUBLE PRECISION

DLAMDA is an array, dimension (N). A copy of the first K eigenvalues which will be used by DLAED3 to form the secular equation.

Q2 Output parameter.

Q2 is DOUBLE PRECISION

Q2 is an array, dimension (LDQ2, N). If ICOMPQ = 0, Q2 is not referenced. Otherwise, a copy of the first K eigenvectors which will be used by DLAED7 in a matrix multiply (DGEMM) to update the new eigenvectors.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of the array Q2. LDQ2 >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first k values of the final deflation-altered z-vector and will be passed to DLAED3.

PERM Output parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Output parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem.

GIVCOL Output parameter.

GIVCOL is INTEGER array, dimension (2, N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Output parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (2, N). Each number indicates the S value to be used in the corresponding Givens rotation.

INDXP Output parameter.

INDXP is INTEGER array, dimension (N)

The permutation used to place deflated values of D at the end of the array. INDXP(1:K) points to the nondeflated D-values and INDXP(K+1:N) points to the deflated eigenvalues.

INDX Output parameter.

INDX is INTEGER array, dimension (N)

The permutation used to sort the contents of D into ascending order.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *claed8*, *slaed8* and *zlaed8*.

4.17.239 dlaed9

dlaed9 finds the roots of the secular equation, as defined by the values in D, Z, and RHO, between KSTART and KSTOP. It makes the appropriate calls to DLAED4 and then stores the new matrix of eigenvectors for use in calculating the next level of Z vectors.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaed9(K, KSTART, KSTOP, N, D, Q, LDQ, RHO, DLAMDA, W, S, LDS,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dlaed9_(const armpl_int_t *k, const armpl_int_t *kstart,
             const armpl_int_t *kstop, const armpl_int_t *n, double *d,
             double *q, const armpl_int_t *ldq, const double *rho,
             const double *dlamda, const double *w, double *s,
             const armpl_int_t *lds, armpl_int_t *info);
```

Parameters

K Input parameter.

K is INTEGER

The number of terms in the rational function to be solved by DLAED4. K >= 0.

KSTART Input parameter.

KSTART is INTEGER

KSTOP Input parameter.

KSTOP is INTEGER

The updated eigenvalues Lambda(I), KSTART <= I <= KSTOP are to be computed. 1 <= KSTART <= KSTOP <= K.

N Input parameter.

N is INTEGER

The number of rows and columns in the Q matrix. N >= K (delation may result in N > K).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). D(I) contains the updated eigenvalues for KSTART <= I <= KSTOP.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N) .

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

RHO Input parameter.

RHO is DOUBLE PRECISION

The value of the parameter in the rank one update equation. RHO >= 0 required.

DLAMDA Input parameter.

DLAMDA is DOUBLE PRECISION

DLAMDA is an array, dimension (K). The first K elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

W Input parameter.

W is DOUBLE PRECISION

W is an array, dimension (K). The first K elements of this array contain the components of the deflation-adjusted updating vector.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (LDS, K). Will contain the eigenvectors of the repaired matrix which will be stored for subsequent Z vector calculation and multiplied by the previously accumulated eigenvectors to update the system.

LDS Input parameter.

LDS is INTEGER

The leading dimension of S. LDS >= max(1, K).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *slaed9*.

4.17.240 dlaeda

dlaeda computes the Z vector corresponding to the merge step in the CURLVLth step of the merge process with TLVLS steps for the CURPBMth problem.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaeda(N, TLVLS, CURLVL, CURPBM, PRMPTR, PERM, GIVPTR, GIVCOL,
                  GIVNUM, Q, QPTR, Z, ZTEMP, INFO)
```

C specification:

```
#include "armpl.h"

void dlaeda_(const armpl_int_t *n, const armpl_int_t *tlvls,
             const armpl_int_t *curlvl, const armpl_int_t *curpbm,
             const armpl_int_t *prmptr, const armpl_int_t *perm,
             const armpl_int_t *givptr, const armpl_int_t *givcol,
             const double *givnum, const double *q, const armpl_int_t *qptr,
             double *z, double *ztemp, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

TLVLS Input parameter.

TLVLS is INTEGER

The total number of merging levels in the overall divide and conquer tree.

CURLVL Input parameter.

CURLVL is INTEGER

The current level in the overall merge routine, 0 <= curlvl <= tlvls.

CURPBM Input parameter.

CURPBM is INTEGER

The current problem in the current level in the overall merge routine (counting from upper left to lower right).

PRMPTR Input parameter.

PRMPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in PERM a level's permutation is stored. PRMPTR(i+1) - PRMPTR(i) indicates the size of the permutation and incidentally the size of the full, non-deflated problem.

PERM Input parameter.

PERM is INTEGER array, dimension (N lg N)

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in GIVCOL a level's Givens rotations are stored. GIVPTR(i+1) - GIVPTR(i) indicates the number of Givens rotations.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (2, N lg N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Input parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (2, N lg N). Each number indicates the S value to be used in the corresponding Givens rotation.

Q Input parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (N**2). Contains the square eigenblocks from previous levels, the starting positions for blocks are given by QPTR.

QPTR Input parameter.

QPTR is INTEGER array, dimension (N+2)

Contains a list of pointers which indicate where in Q an eigenblock is stored. SQRT(QPTR(i+1) - QPTR(i)) indicates the size of the block.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (N). On output this vector contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix).

ZTEMP Output parameter.

ZTEMP is DOUBLE PRECISION

ZTEMP is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *slaeda*.

4.17.241 dlaein

dlaein uses inverse iteration to find a right or left eigenvector corresponding to the eigenvalue (WR,WI) of a real upper Hessenberg matrix H.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaein(RIGHTV, NOINIT, N, H, LDH, WR, WI, VR, VI, B, LDB, WORK,
                  EPS3, SMLNUM, BIGNUM, INFO)
```

C specification:

```
#include "armpl.h"

void dlaein_(const armpl_int_t *rightv, const armpl_int_t *noinit,
             const armpl_int_t *n, const double *h, const armpl_int_t *ldh,
             const double *wr, const double *wi, double *vr, double *vi,
             double *b, const armpl_int_t *ldb, double *work,
             const double *eps3, const double *smlnum, const double *bignum,
             armpl_int_t *info);
```

Parameters

RIGHTV Input parameter.

RIGHTV is LOGICAL

= .TRUE. : compute right eigenvector; = .FALSE.: compute left eigenvector.

NOINIT Input parameter.

NOINIT is LOGICAL

= .TRUE. : no initial vector supplied in (VR, VI). = .FALSE.: initial vector supplied in (VR, VI).

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

H Input parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). The upper Hessenberg matrix H.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

WR Input parameter.

WR is DOUBLE PRECISION

WI Input parameter.

WI is DOUBLE PRECISION

The real and imaginary parts of the eigenvalue of H whose corresponding right or left eigenvector is to be computed.

VR Input and output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (N) .

VI Input and output parameter.

VI is DOUBLE PRECISION

VI is an array, dimension (N). On entry, if NOINIT = .FALSE. and WI = 0.0, VR must contain a real starting vector for inverse iteration using the real eigenvalue WR; if NOINIT = .FALSE. and WI.ne.0.0, VR and VI must contain the real and imaginary parts of a complex starting vector for inverse iteration using the complex eigenvalue (WR, WI); otherwise VR and VI need not be set. On exit, if WI = 0.0 (real eigenvalue), VR contains the computed real eigenvector; if WI.ne.0.0 (complex eigenvalue), VR and VI contain the real and imaginary parts of the computed complex eigenvector. The eigenvector is normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x| + |y|. VI is not referenced if WI = 0.0.

B Output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N) .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= N+1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

EPS3 Input parameter.

EPS3 is DOUBLE PRECISION

A small machine-dependent value which is used to perturb close eigenvalues, and to replace zero pivots.

SMLNUM Input parameter.

SMLNUM is DOUBLE PRECISION

A machine-dependent value close to the underflow threshold.

BIGNUM Input parameter.

BIGNUM is DOUBLE PRECISION

A machine-dependent value close to the overflow threshold.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit = 1: inverse iteration did not converge; VR is set to the last iterate, and so is VI if WI.ne.0.0.

Related Information

For this routine in other precisions, please see *claein*, *slaein* and *zlaein*.

4.17.242 dlaev2

dlaev2 computes the eigendecomposition of a 2-by-2 symmetric matrix

```
[  A   B  ]
[  B   C  ].
```

On return, RT1 is the eigenvalue of larger absolute value, RT2 is the eigenvalue of smaller absolute value, and (CS1,SN1) is the unit right eigenvector for RT1, giving the decomposition

```
[ CS1  SN1 ] [  A   B  ] [ CS1 -SN1 ]  =  [ RT1  0  ]
[-SN1  CS1 ] [  B   C  ] [ SN1  CS1 ]     [  0  RT2 ].
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaev2(A, B, C, RT1, RT2, CS1, SN1)
```

C specification:

```
#include "armpl.h"

void dlaev2_(const double *a, const double *b, const double *c, double *rt1,
             double *rt2, double *cs1, double *sn1);
```

Parameters

A Input parameter.

A is DOUBLE PRECISION

The (1,1) element of the 2-by-2 matrix.

B Input parameter.

B is DOUBLE PRECISION

The (1,2) element and the conjugate of the (2,1) element of the 2-by-2 matrix.

C Input parameter.

C is DOUBLE PRECISION

The (2,2) element of the 2-by-2 matrix.

RT1 Output parameter.

RT1 is DOUBLE PRECISION

The eigenvalue of larger absolute value.

RT2 Output parameter.

RT2 is DOUBLE PRECISION

The eigenvalue of smaller absolute value.

CS1 Output parameter.

CS1 is DOUBLE PRECISION

SN1 Output parameter.

SN1 is DOUBLE PRECISION

The vector (CS1, SN1) is a unit right eigenvector for RT1.

Related Information

For this routine in other precisions, please see *claev2*, *slaev2* and *zlaev2*.

4.17.243 dlaexc

dlaexc swaps adjacent diagonal blocks T11 and T22 of order 1 or 2 in an upper quasi-triangular matrix T by an orthogonal similarity transformation.

T must be in Schur canonical form, that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elemnts equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaexc(WANTQ, N, T, LDT, Q, LDQ, J1, N1, N2, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlaexc_(const armpl_int_t *wantq, const armpl_int_t *n, double *t,
             const armpl_int_t *ldt, double *q, const armpl_int_t *ldq,
             const armpl_int_t *j1, const armpl_int_t *n1,
             const armpl_int_t *n2, double *work, armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

WANTQ is LOGICAL

= .TRUE. : accumulate the transformation in the matrix Q; = .FALSE.: do not accumulate the transformation.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). On entry, the upper quasi-triangular matrix T, in Schur canonical form. On exit, the updated matrix T, again in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if WANTQ is .TRUE., the orthogonal matrix Q. On exit, if WANTQ is .TRUE., the updated matrix Q. If WANTQ is .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; and if WANTQ is .TRUE., LDQ >= N.

J1 Input parameter.

J1 is INTEGER

The index of the first row of the first block T11.

N1 Input parameter.

N1 is INTEGER

The order of the first block T11. N1 = 0, 1 or 2.

N2 Input parameter.

N2 is INTEGER

The order of the second block T22. N2 = 0, 1 or 2.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit = 1: the transformed matrix T would be too far from Schur form; the blocks are not swapped and T and Q are unchanged.

Related Information

For this routine in other precisions, please see *slaexc*.

4.17.244 dlag2

`dlag2` computes the eigenvalues of a 2 x 2 generalized eigenvalue problem A - w B, with scaling as necessary to avoid over-/underflow.

The scaling factor "s" results in a modified eigenvalue equation

```
s A - w B
```

where s is a non-negative scaling factor chosen so that w, w B, and s A do not overflow and, if possible, do not underflow, either.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlag2(A, LDA, B, LDB, SAFMIN, SCALE1, SCALE2, WR1, WR2, WI)
```

C specification:

```
#include "armpl.h"

void dlag2_(const double *a, const armpl_int_t *lda, const double *b,
            const armpl_int_t *ldb, const double *safmin, double *scale1,
            double *scale2, double *wr1, double *wr2, double *wi);
```

Parameters

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, 2). On entry, the 2 x 2 matrix A. It is assumed that its 1-norm is less than 1/SAFMIN. Entries less than sqrt(SAFMIN)*norm(A) are subject to being treated as zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= 2.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, 2). On entry, the 2 x 2 upper triangular matrix B. It is assumed that the one-norm of B is less than 1/SAFMIN. The diagonals should be at least sqrt(SAFMIN) times the largest element of B (in absolute value); if a diagonal is smaller than that, then +/- sqrt(SAFMIN) will be used instead of that diagonal.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= 2.

SAFMIN Input parameter.

SAFMIN is DOUBLE PRECISION

The smallest positive number s.t. 1/SAFMIN does not overflow. (This should always be DLAMCH('S') – it is an argument in order to avoid having to call DLAMCH frequently.)

SCALE1 Output parameter.

SCALE1 is DOUBLE PRECISION

A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the first eigenvalue. If the eigenvalues are complex, then the eigenvalues are (WR1 +/- WI i) / SCALE1 (which may lie outside the exponent range of the machine), SCALE1=SCALE2, and SCALE1 will always be positive. If the eigenvalues are real, then the first (real) eigenvalue is WR1 / SCALE1 , but this may overflow or underflow, and in fact, SCALE1 may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

SCALE2 Output parameter.

SCALE2 is DOUBLE PRECISION

A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the second eigenvalue. If the eigenvalues are complex, then SCALE2=SCALE1. If the eigenvalues are real, then the second (real) eigenvalue is WR2 / SCALE2 , but this may overflow or underflow, and in fact, SCALE2 may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

WR1 Output parameter.

WR1 is DOUBLE PRECISION

If the eigenvalue is real, then WR1 is SCALE1 times the eigenvalue closest to the (2,2) element of A B**(-1). If the eigenvalue is complex, then WR1=WR2 is SCALE1 times the real part of the eigenvalues.

WR2 Output parameter.

WR2 is DOUBLE PRECISION

If the eigenvalue is real, then WR2 is SCALE2 times the other eigenvalue. If the eigenvalue is complex, then WR1=WR2 is SCALE1 times the real part of the eigenvalues.

WI Output parameter.

WI is DOUBLE PRECISION

If the eigenvalue is real, then WI is zero. If the eigenvalue is complex, then WI is SCALE1 times the imaginary part of the eigenvalues. WI will always be non-negative.

Related Information

For this routine in other precisions, please see *slag2*.

4.17.245 dlag2s

dlag2s converts a DOUBLE PRECISION matrix, SA, to a SINGLE PRECISION matrix, A.

RMAX is the overflow for the SINGLE PRECISION arithmetic dlag2s checks that all the entries of A are between -RMAX and RMAX. If not the conversion is aborted and a flag is raised.

This is an auxiliary routine so there is no argument checking.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlag2s(M, N, A, LDA, SA, LDSA, INFO)
```

C specification:

```
#include "armpl.h"

void dlag2s_(const armpl_int_t *m, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, float *sa, const armpl_int_t *ldsa,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of lines of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N coefficient matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SA Output parameter.

SA is REAL

SA is an array, dimension (LDSA, N). On exit, if INFO=0, the M-by-N coefficient matrix SA; if INFO>0, the content of SA is unspecified.

LDSA Input parameter.

LDSA is INTEGER

The leading dimension of the array SA. LDSA >= max(1, M).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. = 1: an entry of the matrix A is greater than the SINGLE PRECISION overflow threshold, in this case, the content of SA in exit is unspecified.

Related Information

It also exists with a native C interface as *LAPACKE_dlag2s*.

4.17.246 dlags2

dlags2 computes 2-by-2 orthogonal matrices U, V and Q, such that if (UPPER) then

```
U**T *A*Q = U**T *( A1 A2 )*Q = ( x  0  )
                  ( 0  A3 )     ( x  x  )
```

and

```
V**T*B*Q = V**T *( B1 B2 )*Q = ( x  0  )
                 ( 0  B3 )     ( x  x  )
```

or if (.NOT.UPPER) then

```
U**T *A*Q = U**T *( A1 0  )*Q = ( x  x  )
                  ( A2 A3 )     ( 0  x  )
```

and

```
V**T*B*Q = V**T*( B1 0  )*Q = ( x  x  )
                ( B2 B3 )     ( 0  x  )
```

The rows of the transformed A and B are parallel, where

```
U = (  CSU  SNU ), V = (  CSV SNV ), Q = (  CSQ   SNQ )
    ( -SNU  CSU )      ( -SNV CSV )      ( -SNQ   CSQ )
```

Z^T denotes the transpose of Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlags2(UPPER, A1, A2, A3, B1, B2, B3, CSU, SNU, CSV, SNV, CSQ,
                  SNQ)
```

C specification:

```
#include "armpl.h"

void dlags2_(const armpl_int_t *upper, const double *a1, const double *a2,
             const double *a3, const double *b1, const double *b2,
             const double *b3, double *csu, double *snu, double *csv,
             double *snv, double *csq, double *snq);
```

Parameters

UPPER Input parameter.

UPPER is LOGICAL

= .TRUE.: the input matrices A and B are upper triangular. = .FALSE.: the input matrices A and B are lower triangular.

A1 Input parameter.

A1 is DOUBLE PRECISION

A2 Input parameter.

A2 is DOUBLE PRECISION

A3 Input parameter.

A3 is DOUBLE PRECISION

On entry, A1, A2 and A3 are elements of the input 2-by-2 upper (lower) triangular matrix A.

B1 Input parameter.

B1 is DOUBLE PRECISION

B2 Input parameter.

B2 is DOUBLE PRECISION

B3 Input parameter.

B3 is DOUBLE PRECISION

On entry, B1, B2 and B3 are elements of the input 2-by-2 upper (lower) triangular matrix B.

CSU Output parameter.

CSU is DOUBLE PRECISION

SNU Output parameter.

SNU is DOUBLE PRECISION

The desired orthogonal matrix U.

CSV Output parameter.

CSV is DOUBLE PRECISION

SNV Output parameter.

SNV is DOUBLE PRECISION

The desired orthogonal matrix V.

CSQ Output parameter.

CSQ is DOUBLE PRECISION

SNQ Output parameter.

SNQ is DOUBLE PRECISION

The desired orthogonal matrix Q.

Related Information

For this routine in other precisions, please see *clags2*, *slags2* and *zlags2*.

4.17.247 dlagtf

dlagtf factorizes the matrix (T - lambda*I), where T is an n by n tridiagonal matrix and lambda is a scalar, as

```
T - lambda*I = PLU,
```

where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column.

The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling.

The parameter LAMBDA is included in the routine so that dlagtf may be used, in conjunction with DLAGTS, to obtain eigenvectors of T by inverse iteration.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlagtf(N, A, LAMBDA, B, C, TOL, D, IN, INFO)
```

C specification:

```
#include "armpl.h"

void dlagtf_(const armpl_int_t *n, double *a, const double *lambda, double *b,
             double *c, const double *tol, double *d, armpl_int_t *in,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix T.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (N). On entry, A must contain the diagonal elements of T.

On exit, A is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T.

LAMBDA Input parameter.

LAMBDA is DOUBLE PRECISION

On entry, the scalar lambda.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (N-1). On entry, B must contain the (n-1) super-diagonal elements of T.

On exit, B is overwritten by the (n-1) super-diagonal elements of the matrix U of the factorization of T.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (N-1). On entry, C must contain the (n-1) sub-diagonal elements of T.

On exit, C is overwritten by the (n-1) sub-diagonal elements of the matrix L of the factorization of T.

TOL Input parameter.

TOL is DOUBLE PRECISION

On entry, a relative tolerance used to indicate whether or not the matrix (T - lambda*I) is nearly singular. TOL should normally be chose as approximately the largest relative error in the elements of T. For example, if the elements of T are correct to about 4 significant figures, then TOL should be set to about 5*10**(-4). If TOL is supplied as less than eps, where eps is the relative machine precision, then the value eps is used in place of TOL.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N-2). On exit, D is overwritten by the (n-2) second super-diagonal elements of the matrix U of the factorization of T.

IN Output parameter.

IN is INTEGER array, dimension (N)

On exit, IN contains details of the permutation matrix P. If an interchange occurred at the kth step of the elimination, then IN(k) = 1, otherwise IN(k) = 0. The element IN(n) returns the smallest positive integer j such that

abs(u(j,j)).le. norm((T - lambda*I)(j))*TOL,

where norm(A(j)) denotes the sum of the absolute values of the jth row of the matrix A. If no such j exists then IN(n) is returned as zero. If IN(n) is returned as positive, then a diagonal element of U is small, indicating that (T - lambda*I) is singular or nearly singular,

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit .lt. 0: if INFO = -k, the kth argument had an illegal value

Related Information

For this routine in other precisions, please see *slagtf*.

4.17.248 dlagtm

dlagtm performs a matrix-vector product of the form

```
B := alpha * A * X + beta * B
```

where A is a tridiagonal matrix of order N, B and X are N by NRHS matrices, and alpha and beta are real scalars, each of which may be 0., 1., or -1.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlagtm(TRANS, N, NRHS, ALPHA, DL, D, DU, X, LDX, BETA, B, LDB)
```

C specification:

```
#include "armpl.h"

void dlagtm_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *alpha, const double *dl, const double *d,
             const double *du, const double *x, const armpl_int_t *ldx,
             const double *beta, double *b, const armpl_int_t *ldb, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': No transpose, B := alpha * A * X + beta * B = 'T': Transpose, B := alpha * A'* X + beta * B = 'C': Conjugate transpose = Transpose

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices X and B.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

The scalar alpha. ALPHA must be 0., 1., or -1.; otherwise, it is assumed to be 0.

DL Input parameter.

DL is DOUBLE PRECISION

DL is an array, dimension (N-1). The (n-1) sub-diagonal elements of T.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of T.

DU Input parameter.

DU is DOUBLE PRECISION

DU is an array, dimension (N-1). The (n-1) super-diagonal elements of T.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NRHS). The N by NRHS matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(N,1).

BETA Input parameter.

BETA is DOUBLE PRECISION

The scalar beta. BETA must be 0., 1., or -1.; otherwise, it is assumed to be 1.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the N by NRHS matrix B. On exit, B is overwritten by the matrix expression B := alpha * A * X + beta * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(N,1).

Related Information

For this routine in other precisions, please see *clagtm*, *slagtm* and *zlagtm*.

4.17.249 dlagts

`dlagts` may be used to solve one of the systems of equations

```
(T - lambda*I)*x = y   or   (T - lambda*I)**T*x = y,
```

where T is an n by n tridiagonal matrix, for x, following the factorization of (T - lambda*I) as

```
(T - lambda*I) = P*L*U ,
```

by routine DLAGTF. The choice of equation to be solved is controlled by the argument JOB, and in each case there is an option to perturb zero or very small diagonal elements of U, this option being intended for use in applications such as inverse iteration.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlagts(JOB, N, A, B, C, D, IN, Y, TOL, INFO)
```

C specification:

```
#include "armpl.h"

void dlagts_(const armpl_int_t *job, const armpl_int_t *n, const double *a,
             const double *b, const double *c, const double *d,
             const armpl_int_t *in, double *y, double *tol,
             armpl_int_t *info);
```

Parameters

JOB Input parameter.

JOB is INTEGER

Specifies the job to be performed by DLAGTS as follows: = 1: The equations (T - lambda*I)x = y are to be solved, but diagonal elements of U are not to be perturbed. = -1: The equations (T - lambda*I)x = y are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument TOL below. = 2: The equations $(T - lambda*I)^T x = y$ are to be solved, but diagonal elements of U are not to be perturbed. = -2: The equations $(T - lambda*I)^T x = y$ are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument TOL below.

N Input parameter.

N is INTEGER

The order of the matrix T.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (N). On entry, A must contain the diagonal elements of U as returned from DLAGTF.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (N-1). On entry, B must contain the first super-diagonal elements of U as returned from DLAGTF.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N-1). On entry, C must contain the sub-diagonal elements of L as returned from DLAGTF.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N-2). On entry, D must contain the second super-diagonal elements of U as returned from DLAGTF.

IN Input parameter.

IN is INTEGER array, dimension (N)

On entry, IN must contain details of the matrix P as returned from DLAGTF.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (N). On entry, the right hand side vector y. On exit, Y is overwritten by the solution vector x.

TOL Input and output parameter.

TOL is DOUBLE PRECISION

On entry, with JOB .lt. 0, TOL should be the minimum perturbation to be made to very small diagonal elements of U. TOL should normally be chosen as about eps*norm(U), where eps is the relative machine precision, but if TOL is supplied as non-positive, then it is reset to eps*max(abs(u(i,j))). If JOB .gt. 0 then TOL is not referenced.

On exit, TOL is changed as described above, only if TOL is non-positive on entry. Otherwise TOL is unchanged.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit .lt. 0: if INFO = -i, the i-th argument had an illegal value .gt. 0: overflow would occur when computing the INFO(th) element of the solution vector x. This can only occur when JOB is supplied as positive and either means that a diagonal element of U is very small, or that the elements of the right-hand side vector y are very large.

Related Information

For this routine in other precisions, please see *slagts*.

4.17.250 dlagv2

dlagv2 computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A,B) where B is upper triangular. This routine computes orthogonal (rotation) matrices given by CSL, SNL and CSR, SNR such that

1) if the pencil (A,B) has two real eigenvalues (include 0/0 or 1/0

```
 types), then

[ a11 a12 ] := [  CSL  SNL ] [ a11 a12 ] [  CSR -SNR ]
[  0  a22 ]    [ -SNL  CSL ] [ a21 a22 ] [  SNR  CSR ]

[ b11 b12 ] := [  CSL  SNL ] [ b11 b12 ] [  CSR -SNR ]
[  0  b22 ]    [ -SNL  CSL ] [  0  b22 ] [  SNR  CSR ],
```

2) if the pencil (A,B) has a pair of complex conjugate eigenvalues,

```
 then

[ a11 a12 ] := [  CSL  SNL ] [ a11 a12 ] [  CSR -SNR ]
[ a21 a22 ]    [ -SNL  CSL ] [ a21 a22 ] [  SNR  CSR ]

[ b11  0  ] := [  CSL  SNL ] [ b11 b12 ] [  CSR -SNR ]
[  0  b22 ]    [ -SNL  CSL ] [  0  b22 ] [  SNR  CSR ]

where b11 >= b22 > 0.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlagv2(A, LDA, B, LDB, ALPHAR, ALPHAI, BETA, CSL, SNL, CSR, SNR)
```

C specification:

```
#include "armpl.h"

void dlagv2_(double *a, const armpl_int_t *lda, double *b,
             const armpl_int_t *ldb, double *alphar, double *alphai,
             double *beta, double *csl, double *snl, double *csr,
             double *snr);
```

Parameters

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, 2). On entry, the 2 x 2 matrix A. On exit, A is overwritten by the ''A-part" of the generalized Schur form.

LDA Input parameter.

LDA is INTEGER

THe leading dimension of the array A. LDA >= 2.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, 2). On entry, the upper triangular 2 x 2 matrix B. On exit, B is overwritten by the ''B-part" of the generalized Schur form.

LDB Input parameter.

LDB is INTEGER

THe leading dimension of the array B. LDB >= 2.

ALPHAR Output parameter.

ALPHAR is DOUBLE PRECISION

ALPHAR is an array, dimension (2) .

ALPHAI Output parameter.

ALPHAI is DOUBLE PRECISION

ALPHAI is an array, dimension (2) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (2). (ALPHAR(k)+i*ALPHAI(k))/BETA(k) are the eigenvalues of the pencil (A, B), k=1,2, i = sqrt(-1). Note that BETA(k) may be zero.

CSL Output parameter.

CSL is DOUBLE PRECISION

The cosine of the left rotation matrix.

SNL Output parameter.

SNL is DOUBLE PRECISION

The sine of the left rotation matrix.

CSR Output parameter.

CSR is DOUBLE PRECISION

The cosine of the right rotation matrix.

SNR Output parameter.

SNR is DOUBLE PRECISION

The sine of the right rotation matrix.

Related Information

For this routine in other precisions, please see *slagv2*.

4.17.251 dlahqr

```
DLAHQR is an auxiliary routine called by DHSEQR to update the
   eigenvalues and Schur decomposition already computed by DHSEQR, by
   dealing with the Hessenberg submatrix in rows and columns ILO to
   IHI.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlahqr(WANTT, WANTZ, N, ILO, IHI, H, LDH, WR, WI, ILOZ, IHIZ, Z,
                  LDZ, INFO)
```

C specification:

```
#include "armpl.h"

void dlahqr_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, double *h, const armpl_int_t *ldh,
             double *wr, double *wi, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, double *z, const armpl_int_t *ldz,
             armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper quasi-triangular in rows and columns IHI+1:N, and that H(ILO,ILO-1) = 0 (unless ILO = 1). DLAHQR works primarily with the Hessenberg submatrix in rows and columns ILO to IHI, but applies transformations to all of H if WANTT is .TRUE.. 1 <= ILO <= max(1, IHI); IHI <= N.

H Input and output parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO is zero and if WANTT is .TRUE., H is upper quasi-triangular in rows and columns ILO:IHI, with any 2-by-2 diagonal blocks in standard form. If INFO is zero and WANTT is .FALSE., the contents of H are unspecified on exit. The output state of H if INFO is nonzero is given below under the description of INFO.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

WR Output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (N) .

WI Output parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (N). The real and imaginary parts, respectively, of the computed eigenvalues ILO to IHI are stored in the corresponding elements of WR and WI. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with WI(i) > 0 and WI(i+1) < 0. If WANTT is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with WR(i) = H(i,i), and, if H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) = sqrt(H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 <= ILOZ <= ILO; IHI <= IHIZ <= N.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If WANTZ is .TRUE., on entry Z must contain the current matrix Z of transformations accumulated by DHSEQR, and on exit Z has been updated; transformations are applied only to the submatrix Z(ILOZ:IHIZ,ILO:IHI). If WANTZ is .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: If INFO = i, DLAHQR failed to compute all the eigenvalues ILO to IHI in a total of 30 iterations per eigenvalue; elements i+1:ihi of WR and WI contain those eigenvalues which have been successfully computed.

If INFO .GT. 0 and WANTT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO thorugh INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit (*) (initial value of H)*U = U*(final value of H) where U is an orthognal matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit (final value of Z) = (initial value of Z)*U where U is the orthogonal matrix in (*) (regardless of the value of WANTT.)

Related Information

For this routine in other precisions, please see *clahqr*, *slahqr* and *zlahqr*.

4.17.252 dlahr2

dlahr2 reduces the first NB columns of A real general n-BY-(n-k+1) matrix A so that elements below the k-th subdiagonal are zero. The reduction is performed by an orthogonal similarity transformation Q^T * A * Q. The routine returns the matrices V and T which determine Q as a block reflector I - V*T*V^T , and also the matrix Y = A * V * T.

This is an auxiliary routine called by DGEHRD.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlahr2(N, K, NB, A, LDA, TAU, T, LDT, Y, LDY)
```

C specification:

```
#include "armpl.h"

void dlahr2_(const armpl_int_t *n, const armpl_int_t *k,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *nb, double *a, const armpl_int_t *lda,
                double *tau, double *t, const armpl_int_t *ldt, double *y,
                const armpl_int_t *ldy);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A.

K Input parameter.

K is INTEGER

The offset for the reduction. Elements below the k-th subdiagonal in the first NB columns are reduced to zero. K < N.

NB Input parameter.

NB is INTEGER

The number of columns to be reduced.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA,N-K+1). On entry, the n-by-(n-k+1) general matrix A. On exit, the elements on and above the k-th subdiagonal in the first NB columns are overwritten with the corresponding elements of the reduced matrix; the elements below the k-th subdiagonal, with the array TAU, represent the matrix Q as a product of elementary reflectors. The other columns of A are unchanged. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (NB). The scalar factors of the elementary reflectors. See Further Details.

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, NB). The upper triangular matrix T.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

Y Output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension (LDY, NB). The n-by-nb matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= N.

Related Information

For this routine in other precisions, please see *clahr2*, *slahr2* and *zlahr2*.

4.17.253 dlaic1

`dlaic1` applies one step of incremental condition estimation in its simplest version:

Let x, twonorm(x) = 1, be an approximate singular vector of an j-by-j lower triangular matrix L, such that

```
twonorm(L*x) = sest
```

Then `dlaic1` computes sestpr, s, c such that the vector

```
       [ s*x ]
xhat = [  c  ]
```

is an approximate singular vector of

```
       [ L       0  ]
Lhat = [ w**T gamma ]
```

in the sense that

```
twonorm(Lhat*xhat) = sestpr.
```

Depending on JOB, an estimate for the largest or smallest singular value is computed.

Note that [s c]^T and sestpr**2 is an eigenpair of the system

```
diag(sest*sest, 0) + [alpha  gamma] * [ alpha ]
                                      [ gamma ]
```

where alpha = x^T *w.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaic1(JOB, J, X, SEST, W, GAMMA, SESTPR, S, C)
```

C specification:

```
#include "armpl.h"

void dlaic1_(const armpl_int_t *job, const armpl_int_t *j, const double *x,
             const double *sest, const double *w, const double *gamma,
             double *sestpr, double *s, double *c);
```

Parameters

JOB Input parameter.

JOB is INTEGER

= 1: an estimate for the largest singular value is computed. = 2: an estimate for the smallest singular value is computed.

J Input parameter.

J is INTEGER

Length of X and W

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension (J). The j-vector x.

SEST Input parameter.

SEST is DOUBLE PRECISION

Estimated singular value of j by j matrix L

W Input parameter.

W is DOUBLE PRECISION

W is an array, dimension (J). The j-vector w.

GAMMA Input parameter.

GAMMA is DOUBLE PRECISION

The diagonal element gamma.

SESTPR Output parameter.

SESTPR is DOUBLE PRECISION

Estimated singular value of (j+1) by (j+1) matrix Lhat.

S Output parameter.

S is DOUBLE PRECISION

Sine needed in forming xhat.

C Output parameter.

C is DOUBLE PRECISION

Cosine needed in forming xhat.

Related Information

For this routine in other precisions, please see *claic1*, *slaic1* and *zlaic1*.

4.17.254 dlaisnan

This routine is not for general use. It exists solely to avoid over-optimization in DISNAN.

DLAISNAN checks for NaNs by comparing its two arguments for inequality. NaN is the only floating-point value where NaN != NaN returns .TRUE. To check for NaNs, pass the same variable as both arguments.

A compiler must assume that the two arguments are not the same variable, and the test will not be optimized away. Interprocedural or whole-program optimization may delete this test. The ISNAN functions will be replaced by the correct Fortran 03 intrinsic once the intrinsic is widely available.

Syntax

Fortran specification:

```
use armpl_library

logical function dlaisnan(DIN1, DIN2)
```

C specification:

```
#include "armpl.h"

armpl_int_t dlaisnan_(const double *din1, const double *din2);
```

Parameters

DIN1 Input parameter.

DIN1 is DOUBLE PRECISION

DIN2 Input parameter.

DIN2 is DOUBLE PRECISION

Two numbers to compare for inequality.

Related Information

For this routine in other precisions, please see *slaisnan*.

4.17.255 dlaln2

dlaln2 solves a system of the form (ca A - w D) X = s B or (ca A^T - w D) X = s B with possible scaling ("s") and perturbation of A. (A^T means A-transpose.)

A is an NA x NA real matrix, ca is a real scalar, D is an NA x NA real diagonal matrix, w is a real or complex value, and X and B are NA x 1 matrices – real if w is real, complex if w is complex. NA may be 1 or 2.

If w is complex, X and B are represented as NA x 2 matrices, the first column of each being the real part and the second being the imaginary part.

"s" is a scaling factor (.LE. 1), computed by dlaln2, which is so chosen that X can be computed without overflow. X is further scaled if necessary to assure that norm(ca A - w D)*norm(X) is less than overflow.

If both singular values of (ca A - w D) are less than SMIN, SMIN*identity will be used instead of (ca A - w D). If only one singular value is less than SMIN, one element of (ca A - w D) will be perturbed enough to make the smallest singular value roughly SMIN. If both singular values are at least SMIN, (ca A - w D) will not be perturbed. In any case, the perturbation will be at most some small multiple of max(SMIN, ulp*norm(ca A - w D)). The singular values are computed by infinity-norm approximations, and thus will only be correct to a factor of 2 or so.

Note: all input quantities are assumed to be smaller than overflow by a reasonable factor. (See BIGNUM.)

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaln2(LTRANS, NA, NW, SMIN, CA, A, LDA, D1, D2, B, LDB, WR, WI, X,
                  LDX, SCALE, XNORM, INFO)
```

C specification:

```
#include "armpl.h"

void dlaln2_(const armpl_int_t *ltrans, const armpl_int_t *na,
             const armpl_int_t *nw, const double *smin, const double *ca,
             const double *a, const armpl_int_t *lda, const double *d1,
             const double *d2, const double *b, const armpl_int_t *ldb,
             const double *wr, const double *wi, double *x,
             const armpl_int_t *ldx, double *scale, double *xnorm,
             armpl_int_t *info);
```

Parameters

LTRANS Input parameter.

LTRANS is LOGICAL

=.TRUE.: A-transpose will be used. =.FALSE.: A will be used (not transposed.)

NA Input parameter.

NA is INTEGER

The size of the matrix A. It may (only) be 1 or 2.

NW Input parameter.

NW is INTEGER

1 if “w” is real, 2 if “w” is complex. It may only be 1 or 2.

SMIN Input parameter.

SMIN is DOUBLE PRECISION

The desired lower bound on the singular values of A. This should be a safe distance away from underflow or overflow, say, between (underflow/machine precision) and (machine precision * overflow). (See BIGNUM and ULP.)

CA Input parameter.

CA is DOUBLE PRECISION

The coefficient c, which A is multiplied by.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, NA). The NA x NA matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. It must be at least NA.

D1 Input parameter.

D1 is DOUBLE PRECISION

The 1,1 element in the diagonal matrix D.

D2 Input parameter.

D2 is DOUBLE PRECISION

The 2,2 element in the diagonal matrix D. Not used if NA=1.

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NW). The NA x NW matrix B (right-hand side). If NW=2 (“w” is complex), column 1 contains the real part of B and column 2 contains the imaginary part.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. It must be at least NA.

WR Input parameter.

WR is DOUBLE PRECISION

The real part of the scalar “w”.

WI Input parameter.

WI is DOUBLE PRECISION

The imaginary part of the scalar “w”. Not used if NW=1.

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, NW). The NA x NW matrix X (unknowns), as computed by DLALN2. If NW=2 (“w” is complex), on exit, column 1 will contain the real part of X and column 2 will contain the imaginary part.

LDX Input parameter.

LDX is INTEGER

The leading dimension of X. It must be at least NA.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

The scale factor that B must be multiplied by to insure that overflow does not occur when computing X. Thus, (ca A - w D) X will be SCALE*B, not B (ignoring perturbations of A.) It will be at most 1.

XNORM Output parameter.

XNORM is DOUBLE PRECISION

The infinity-norm of X, when X is regarded as an NA x NW real matrix.

INFO Output parameter.

INFO is INTEGER

An error flag. It will be set to zero if no error occurs, a negative number if an argument is in error, or a positive number if ca A - w D had to be perturbed. The possible values are: = 0: No error occurred, and (ca A - w D) did not have to be perturbed. = 1: (ca A - w D) had to be perturbed to make its smallest (or only) singular value greater than SMIN. NOTE: In the interests of speed, this routine does not check the inputs for errors.

Related Information

For this routine in other precisions, please see *slaln2*.

4.17.256 dlals0

`dlals0` applies back the multiplying factors of either the left or the right singular vector matrix of a diagonal matrix appended by a row to the right hand side matrix B in solving the least squares problem using the divide-and-conquer SVD approach.

For the left singular vector matrix, three types of orthogonal matrices are involved:

(1L) Givens rotations: the number of such rotations is GIVPTR; the

```
pairs of columns/rows they were applied to are stored in GIVCOL;
and the C- and S-values of these rotations are stored in GIVNUM.
```

(2L) Permutation. The (NL+1)-st row of B is to be moved to the first

```
row, and for J=2:N, PERM(J)-th row of B is to be moved to the
J-th row.
```

(3L) The left singular vector matrix of the remaining matrix.

For the right singular vector matrix, four types of orthogonal matrices are involved:

(1R) The right singular vector matrix of the remaining matrix.

(2R) If SQRE = 1, one extra Givens rotation to generate the right

```
null space.
```

(3R) The inverse transformation of (2L).

(4R) The inverse transformation of (1L).

Syntax

Fortran specification:

```
use armpl_library

subroutine dlals0(ICOMPQ, NL, NR, SQRE, NRHS, B, LDB, BX, LDBX, PERM, GIVPTR,
                  GIVCOL, LDGCOL, GIVNUM, LDGNUM, POLES, DIFL, DIFR, Z, K, C,
                  S, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlals0_(const armpl_int_t *icompq, const armpl_int_t *nl,
             const armpl_int_t *nr, const armpl_int_t *sqre,
             const armpl_int_t *nrhs, double *b, const armpl_int_t *ldb,
             double *bx, const armpl_int_t *ldbx, const armpl_int_t *perm,
             const armpl_int_t *givptr, const armpl_int_t *givcol,
             const armpl_int_t *ldgcol, const double *givnum,
             const armpl_int_t *ldgnum, const double *poles,
             const double *difl, const double *difr, const double *z,
             const armpl_int_t *k, const double *c, const double *s,
             double *work, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in factored form: = 0: Left singular vector matrix. = 1: Right singular vector matrix.

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has row dimension N = NL + NR + 1, and column dimension M = N + SQRE.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B and BX. NRHS must be at least 1.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem in rows 1 through M. On output, B contains the solution X in rows 1 through N.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB must be at least max(1,MAX(M, N)).

BX Output parameter.

BX is DOUBLE PRECISION

BX is an array, dimension (LDBX, NRHS) .

LDBX Input parameter.

LDBX is INTEGER

The leading dimension of BX.

PERM Input parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) applied to the two blocks.

GIVPTR Input parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2)

Each pair of numbers indicates a pair of rows/columns involved in a Givens rotation.

LDGCOL Input parameter.

LDGCOL is INTEGER

The leading dimension of GIVCOL, must be at least N.

GIVNUM Input parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (LDGNUM, 2). Each number indicates the C or S value used in the corresponding Givens rotation.

LDGNUM Input parameter.

LDGNUM is INTEGER

The leading dimension of arrays DIFR, POLES and GIVNUM, must be at least K.

POLES Input parameter.

POLES is DOUBLE PRECISION

POLES is an array, dimension (LDGNUM, 2). On entry, POLES(1:K, 1) contains the new singular values obtained from solving the secular equation, and POLES(1:K, 2) is an array containing the poles in the secular equation.

DIFL Input parameter.

DIFL is DOUBLE PRECISION

DIFL is an array, dimension (K).. On entry, DIFL(I) is the distance between I-th updated (undeflated) singular value and the I-th (undeflated) old singular value.

DIFR Input parameter.

DIFR is DOUBLE PRECISION

DIFR is an array, dimension (LDGNUM, 2).. On entry, DIFR(I, 1) contains the distances between I-th updated (undeflated) singular value and the I+1-th (undeflated) old singular value. And DIFR(I, 2) is the normalizing factor for the I-th right singular vector.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (K). Contain the components of the deflation-adjusted updating row vector.

K Input parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. 1 <= K <=N.

C Input parameter.

C is DOUBLE PRECISION

C contains garbage if SQRE =0 and the C-value of a Givens rotation related to the right null space if SQRE = 1.

S Input parameter.

S is DOUBLE PRECISION

S contains garbage if SQRE =0 and the S-value of a Givens rotation related to the right null space if SQRE = 1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (K) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *clals0*, *slals0* and *zlals0*.

4.17.257 dlalsa

dlalsa is an itermediate step in solving the least squares problem by computing the SVD of the coefficient matrix in compact form (The singular vectors are computed as products of simple orthorgonal matrices.).

If ICOMPQ = 0, dlalsa applies the inverse of the left singular vector matrix of an upper bidiagonal matrix to the right hand side; and if ICOMPQ = 1, dlalsa applies the right singular vector matrix to the right hand side. The singular vector matrices were generated in compact form by dlalsa.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlalsa(ICOMPQ, SMLSIZ, N, NRHS, B, LDB, BX, LDBX, U, LDU, VT, K,
                  DIFL, DIFR, Z, POLES, GIVPTR, GIVCOL, LDGCOL, PERM, GIVNUM,
                  C, S, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlalsa_(const armpl_int_t *icompq, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *nrhs, double *b,
             const armpl_int_t *ldb, double *bx, const armpl_int_t *ldbx,
             const double *u, const armpl_int_t *ldu, const double *vt,
             const armpl_int_t *k, const double *difl, const double *difr,
             const double *z, const double *poles, const armpl_int_t *givptr,
             const armpl_int_t *givcol, const armpl_int_t *ldgcol,
             const armpl_int_t *perm, const double *givnum, const double *c,
             const double *s, double *work, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether the left or the right singular vector matrix is involved. = 0: Left singular vector matrix = 1: Right singular vector matrix

SMLSIZ Input parameter.

SMLSIZ is INTEGER

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

N is INTEGER

The row and column dimensions of the upper bidiagonal matrix.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B and BX. NRHS must be at least 1.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem in rows 1 through M. On output, B contains the solution X in rows 1 through N.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B in the calling subprogram. LDB must be at least max(1,MAX(M, N)).

BX Output parameter.

BX is DOUBLE PRECISION

BX is an array, dimension (LDBX, NRHS). On exit, the result of applying the left or right singular vector matrix to B.

LDBX Input parameter.

LDBX is INTEGER

The leading dimension of BX.

U Input parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, SMLSIZ).. On entry, U contains the left singular vector matrices of all subproblems at the bottom level.

LDU Input parameter.

LDU is INTEGER, LDU = > N.

The leading dimension of arrays U, VT, DIFL, DIFR, POLES, GIVNUM, and Z.

VT Input parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDU, SMLSIZ+1).. On entry, VT^T contains the right singular vector matrices of all subproblems at the bottom level.

K Input parameter.

K is INTEGER array, dimension (N).

DIFL Input parameter.

DIFL is DOUBLE PRECISION

DIFL is an array, dimension (LDU, NLVL).. where NLVL = INT(log_2 (N/(SMLSIZ+1))) + 1.

DIFR Input parameter.

DIFR is DOUBLE PRECISION

DIFR is an array, dimension (LDU, 2 * NLVL).. On entry, DIFL(*, I) and DIFR(*, 2 * I -1) record distances between singular values on the I-th level and singular values on the (I -1)-th level, and DIFR(*, 2 * I) record the normalizing factors of the right singular vectors matrices of subproblems on I-th level.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDU, NLVL).. On entry, Z(1, I) contains the components of the deflation- adjusted updating row vector for subproblems on the I-th level.

POLES Input parameter.

POLES is DOUBLE PRECISION

POLES is an array, dimension (LDU, 2 * NLVL).. On entry, POLES(*, 2 * I -1: 2 * I) contains the new and old singular values involved in the secular equations on the I-th level.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N).

On entry, GIVPTR(I) records the number of Givens rotations performed on the I-th problem on the computation tree.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2 * NLVL).

On entry, for each I, GIVCOL(*, 2 * I - 1: 2 * I) records the locations of Givens rotations performed on the I-th level on the computation tree.

LDGCOL Input parameter.

LDGCOL is INTEGER, LDGCOL = > N.

The leading dimension of arrays GIVCOL and PERM.

PERM Input parameter.

PERM is INTEGER array, dimension (LDGCOL, NLVL).

On entry, PERM(*, I) records permutations done on the I-th level of the computation tree.

GIVNUM Input parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (LDU, 2 * NLVL).. On entry, GIVNUM(*, 2 *I -1 : 2 * I) records the C- and S- values of Givens rotations performed on the I-th level on the computation tree.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N).. On entry, if the I-th subproblem is not square, C(I) contains the C-value of a Givens rotation related to the right null space of the I-th subproblem.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (N).. On entry, if the I-th subproblem is not square, S(I) contains the S-value of a Givens rotation related to the right null space of the I-th subproblem.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (3*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *clalsa*, *slalsa* and *zlalsa*.

4.17.258 dlalsd

dlalsd uses the singular value decomposition of A to solve the least squares problem of finding X to minimize the Euclidean norm of each column of A*X-B, where A is N-by-N upper bidiagonal, and X and B are N-by-NRHS. The solution X overwrites B.

The singular values of A smaller than RCOND times the largest singular value are treated as zero in solving the least squares problem; in this case a minimum norm solution is returned. The actual singular values are returned in D in ascending order.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlalsd(UPLO, SMLSIZ, N, NRHS, D, E, B, LDB, RCOND, RANK, WORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlalsd_(const char *uplo, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *nrhs, double *d,
             double *e, double *b, const armpl_int_t *ldb,
             const double *rcond, armpl_int_t *rank, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': D and E define an upper bidiagonal matrix. = 'L': D and E define a lower bidiagonal matrix.

SMLSIZ Input parameter.

SMLSIZ is INTEGER

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

N is INTEGER

The dimension of the bidiagonal matrix. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B. NRHS must be at least 1.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry D contains the main diagonal of the bidiagonal matrix. On exit, if INFO = 0, D contains its singular values.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). Contains the super-diagonal entries of the bidiagonal matrix. On exit, E has been destroyed.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem. On output, B contains the solution X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B in the calling subprogram. LDB must be at least max(1, N).

RCOND Input parameter.

RCOND is DOUBLE PRECISION

The singular values of A less than or equal to RCOND times the largest singular value are treated as zero in solving the least squares problem. If RCOND is negative, machine precision is used instead. For example, if diag(S)*X=B were the least squares problem, where diag(S) is a diagonal matrix of singular values, the solution would be X(i) = B(i) / S(i) if S(i) is greater than RCOND*max(S), and X(i) = 0 if S(i) is less than or equal to RCOND*max(S).

RANK Output parameter.

RANK is INTEGER

The number of singular values of A greater than RCOND times the largest singular value.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension at least. (9* N + 2*N* SMLSIZ + 8*N*NLVL + N* NRHS + (SMLSIZ+1)**2), where NLVL = max(0, INT(log_2 (N/(SMLSIZ+1))) + 1).

IWORK Output parameter.

IWORK is INTEGER array, dimension at least

(3*N*NLVL + 11*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute a singular value while working on the submatrix lying in rows and columns INFO/(N+1) through MOD(INFO,N+1).

Related Information

For this routine in other precisions, please see *clalsd*, *slalsd* and *zlalsd*.

4.17.259 dlamrg

dlamrg will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlamrg(N1, N2, A, DTRD1, DTRD2, INDEX)
```

C specification:

```
#include "armpl.h"

void dlamrg_(const armpl_int_t *n1, const armpl_int_t *n2, const double *a,
             const armpl_int_t *dtrd1, const armpl_int_t *dtrd2,
             armpl_int_t *index);
```

Parameters

N1 Input parameter.

N1 is INTEGER

N2 Input parameter.

N2 is INTEGER

These arguments contain the respective lengths of the two sorted lists to be merged.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (N1+N2). The first N1 elements of A contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final N2 elements.

DTRD1 Input parameter.

DTRD1 is INTEGER

DTRD2 Input parameter.

DTRD2 is INTEGER

These are the strides to be taken through the array A. Allowable strides are 1 and -1. They indicate whether a subset of A is sorted in ascending (DTRDx = 1) or descending (DTRDx = -1) order.

INDEX Output parameter.

INDEX is INTEGER array, dimension (N1+N2)

On exit this array will contain a permutation such that if B(I) = A(INDEX(I)) for I=1,N1+N2, then B will be sorted in ascending order.

Related Information

For this routine in other precisions, please see *slamrg*.

4.17.260 dlamswlq

DLAMQRTS overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by short wide LQ factorization (DLASWLQ)

Syntax

Fortran specification:

```
use armpl_library

subroutine dlamswlq(SIDE, TRANS, M, N, K, MB, NB, A, LDA, T, LDT, C, LDC,
                    WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlamswlq_(const char *side, const char *trans, const armpl_int_t *m,
               const armpl_int_t *n, const armpl_int_t *k,
               const armpl_int_t *mb, const armpl_int_t *nb, double *a,
               const armpl_int_t *lda, const double *t,
               const armpl_int_t *ldt, double *c, const armpl_int_t *ldc,
               double *work, const armpl_int_t *lwork, armpl_int_t *info,
               ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0;

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. M >= MB >= 1

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. NB > M.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. MB > M.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the blocked elementary reflector H(i), for i = 1,2,...,k, as returned by DLASWLQ in the first k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension. (M * Number of blocks(CEIL(N-K/NB-K)), The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) DOUBLE PRECISION

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, NB) * MB; if SIDE = 'R', LWORK >= max(1, M) * MB. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal

size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clamswlq*, *slamswlq* and *zlamswlq*.

4.17.261 dlamtsqr

DLAMTSQR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by tall skinny QR factorization (DLATSQR)

Syntax

Fortran specification:

```
use armpl_library

subroutine dlamtsqr(SIDE, TRANS, M, N, K, MB, NB, A, LDA, T, LDT, C, LDC,
                    WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlamtsqr_(const char *side, const char *trans, const armpl_int_t *m,
               const armpl_int_t *n, const armpl_int_t *k,
               const armpl_int_t *mb, const armpl_int_t *nb, double *a,
               const armpl_int_t *lda, const double *t,
               const armpl_int_t *ldt, double *c, const armpl_int_t *ldc,
               double *work, const armpl_int_t *lwork, armpl_int_t *info,
               ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0;

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. MB > N. (must be the same as DLATSQR)

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. N >= NB >= 1.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the blockedelementary reflector H(i), for i = 1,2,. . . ,k, as returned by DLATSQR in the first k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension. (N * Number of blocks(CEIL(M-K/MB-K)), The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) DOUBLE PRECISION

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If SIDE = 'L', LWORK >= max(1, N)*NB; if SIDE = 'R', LWORK >= max(1, MB)*NB. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clamtsqr*, *slamtsqr* and *zlamtsqr*.

4.17.262 dlaneg

dlaneg computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal T - sigma I = L D L^T. This implementation works directly on the factors without forming the tridiagonal matrix T. The Sturm count is also the number of eigenvalues of T less than sigma.

This routine is called from DLARRB.

The current routine does not use the PIVMIN parameter but rather requires IEEE-754 propagation of Infinities and NaNs. This routine also has no input range restrictions but does require default exception handling such that x/0 produces Inf when x is non-zero, and Inf/Inf produces NaN. For more information, see:

```
Marques, Riedy, and Voemel, "Benefits of IEEE-754 Features in
Modern Symmetric Tridiagonal Eigensolvers," SIAM Journal on
Scientific Computing, v28, n5, 2006.  DOI 10.1137/050641624
(Tech report version in LAWN 172 with the same title.)
```

Syntax

Fortran specification:

```
use armpl_library

integer function dlaneg(N, D, LLD, SIGMA, PIVMIN, R)
```

C specification:

```
#include "armpl.h"

armpl_int_t dlaneg_(const armpl_int_t *n, const double *d, const double *lld,
                    const double *sigma, const double *pivmin,
                    const armpl_int_t *r);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The N diagonal elements of the diagonal matrix D.

LLD Input parameter.

LLD is DOUBLE PRECISION

LLD is an array, dimension (N-1). The (N-1) elements L(i)*L(i)*D(i).

SIGMA Input parameter.

SIGMA is DOUBLE PRECISION

Shift amount in T - sigma I = L D L^T.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot in the Sturm sequence. May be used when zero pivots are encountered on non-IEEE-754 architectures.

R Input parameter.

R is INTEGER

The twist index for the twisted factorization that is used for the negcount.

Related Information

For this routine in other precisions, please see *slaneg*.

4.17.263 dlangb

dlangb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n band matrix A, with kl sub-diagonals and ku super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlangb(NORM, N, KL, KU, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

double dlangb_(const char *norm, const armpl_int_t *n, const armpl_int_t *kl,
               const armpl_int_t *ku, const double *ab,
               const armpl_int_t *ldab, double *work, ... );
```

Returns

DLANGB = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in DLANGB as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, DLANGB is set to zero.

KL Input parameter.

KL is INTEGER

The number of sub-diagonals of the matrix A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of super-diagonals of the matrix A. KU >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clangb*, *slangb* and *zlangb*.

4.17.264 dlange

dlange returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlange(NORM, M, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

double dlange_(const char *norm, const armpl_int_t *m, const armpl_int_t *n,
               const double *a, const armpl_int_t *lda, double *work, ... );
```

Returns

DLANGE = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in DLANGE as described above.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0. When M = 0, DLANGE is set to zero.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0. When N = 0, DLANGE is set to zero.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The m by n matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clange*, *slange* and *zlange*. It also exists with a native C interface as *LAPACKE_dlange*.

4.17.265 dlangt

dlangt returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlangt(NORM, N, DL, D, DU)
```

C specification:

```
#include "armpl.h"

double dlangt_(const char *norm, const armpl_int_t *n, const double *dl,
               const double *d, const double *du, ... );
```

Returns

DLANGT = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in DLANGT as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, DLANGT is set to zero.

DL Input parameter.

DL is DOUBLE PRECISION

DL is an array, dimension (N-1). The (n-1) sub-diagonal elements of A.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of A.

DU Input parameter.

DU is DOUBLE PRECISION

DU is an array, dimension (N-1). The (n-1) super-diagonal elements of A.

Related Information

For this routine in other precisions, please see *clangt*, *slangt* and *zlangt*.

4.17.266 dlanhs

`dlanhs` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hessenberg matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlanhs(NORM, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

double dlanhs_(const char *norm, const armpl_int_t *n, const double *a,
               const armpl_int_t *lda, double *work, ... );
```

Returns

DLANHS = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in DLANHS as described above.

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0. When `N` = 0, DLANHS is set to zero.

A Input parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). The n by n upper Hessenberg matrix A; the part of `A` below the first sub-diagonal is not referenced.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(`N`,1).

WORK Output parameter.

`WORK` is `DOUBLE PRECISION`

`WORK` is an array, dimension (MAX(1,LWORK)),. where LWORK >= `N` when `NORM` = ‘I’; otherwise, `WORK` is not referenced.

Related Information

For this routine in other precisions, please see *clanhs*, *slanhs* and *zlanhs*.

4.17.267 dlansb

`dlansb` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n symmetric band matrix A, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlansb(NORM, UPLO, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

double dlansb_(const char *norm, const char *uplo, const armpl_int_t *n,
               const armpl_int_t *k, const double *ab,
               const armpl_int_t *ldab, double *work, ... );
```

Returns

DLANSB = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in DLANSB as described above.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the upper or lower triangular part of the band matrix A is supplied. = ‘`U`’: Upper triangular part is supplied = ‘`L`’: Lower triangular part is supplied

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0. When `N` = 0, DLANSB is set to zero.

K Input parameter.

`K` is `INTEGER`

The number of super-diagonals or sub-diagonals of the band matrix A. `K` >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The upper or lower triangle of the symmetric band matrix A, stored in the first K+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clansb*, *slansb* and *zlansb*.

4.17.268 dlansf

dlansf returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric matrix A in RFP format.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlansf(NORM, TRANSR, UPLO, N, A, WORK)
```

C specification:

```
#include "armpl.h"

double dlansf_(const char *norm, const char *transr, const char *uplo,
               const armpl_int_t *n, const double *a, double *work, ... );
```

Returns

DLANSF = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in DLANSF as described above.

TRANSR Input parameter.

TRANSR is CHARACTER*1

Specifies whether the RFP format of A is normal or transposed format. = 'N': RFP format is Normal; = 'T': RFP format is Transpose.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the RFP matrix A came from an upper or lower triangular matrix as follows: = 'U': RFP A came from an upper triangular matrix; = 'L': RFP A came from a lower triangular matrix.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, DLANSF is set to zero.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (N*(N+1)/2);. On entry, the upper (if UPLO = 'U') or lower (if UPLO = 'L') part of the symmetric matrix A stored in RFP format. See the "Notes" below for more details. Unchanged on exit.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *slansf*.

4.17.269 dlansp

dlansp returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlansp(NORM, UPLO, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

double dlansp_(const char *norm, const char *uplo, const armpl_int_t *n,
               const double *ap, double *work, ... );
```

Returns

DLANSP = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in DLANSP as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is supplied. = 'U': Upper triangular part of A is supplied = 'L': Lower triangular part of A is supplied

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, DLANSP is set to zero.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clansp*, *slansp* and *zlansp*.

4.17.270 dlanst

dlanst returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlanst(NORM, N, D, E)
```

C specification:

```
#include "armpl.h"

double dlanst_(const char *norm, const armpl_int_t *n, const double *d,
               const double *e, ... );
```

Returns

DLANST = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in DLANST as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, DLANST is set to zero.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of A.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The (n-1) sub-diagonal or super-diagonal elements of A.

Related Information

For this routine in other precisions, please see *slanst*.

4.17.271 dlansy

dlansy returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlansy(NORM, UPLO, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

double dlansy_(const char *norm, const char *uplo, const armpl_int_t *n,
               const double *a, const armpl_int_t *lda, double *work, ... );
```

Returns

DLANSY = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in DLANSY as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced. = ‘U’: Upper triangular part of A is referenced = ‘L’: Lower triangular part of A is referenced

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, DLANSY is set to zero.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = ‘U’, the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = ‘L’, the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = ‘I’ or ‘1’ or ‘O’; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clansy*, *slansy* and *zlansy*. It also exists with a native C interface as *LAPACKE_dlansy*.

4.17.272 dlantb

`dlantb` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n triangular band matrix A, with (k + 1) diagonals.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlantb(NORM, UPLO, DIAG, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

double dlantb_(const char *norm, const char *uplo, const char *diag,
               const armpl_int_t *n, const armpl_int_t *k, const double *ab,
               const armpl_int_t *ldab, double *work, ... );
```

Returns

DLANTB = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in DLANTB as described above.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the matrix A is upper or lower triangular. = ‘`U`’: Upper triangular = ‘`L`’: Lower triangular

DIAG Input parameter.

`DIAG` is `CHARACTER*1`

Specifies whether or not the matrix A is unit triangular. = ‘`N`’: Non-unit triangular = ‘`U`’: Unit triangular

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0. When `N` = 0, DLANTB is set to zero.

K Input parameter.

`K` is `INTEGER`

The number of super-diagonals of the matrix A if `UPLO` = ‘`U`’, or the number of sub-diagonals of the matrix A if `UPLO` = ‘`L`’. `K` >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first k+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k). Note that when DIAG = 'U', the elements of the array AB corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clantb*, *slantb* and *zlantb*.

4.17.273 dlantp

dlantp returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlantp(NORM, UPLO, DIAG, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

double dlantp_(const char *norm, const char *uplo, const char *diag,
               const armpl_int_t *n, const double *ap, double *work, ... );
```

Returns

DLANTP = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in DLANTP as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, DLANTP is set to zero.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. Note that when DIAG = 'U', the elements of the array AP corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clantp*, *slantp* and *zlantp*.

4.17.274 dlantr

dlantr returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlantr(NORM, UPLO, DIAG, M, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

double dlantr_(const char *norm, const char *uplo, const char *diag,
               const armpl_int_t *m, const armpl_int_t *n, const double *a,
               const armpl_int_t *lda, double *work, ... );
```

Returns

DLANTR = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in DLANTR as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower trapezoidal. = ‘U’: Upper trapezoidal = ‘L’: Lower trapezoidal Note that A is triangular instead of trapezoidal if M = N.

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A has unit diagonal. = ‘N’: Non-unit diagonal = ‘U’: Unit diagonal

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0, and if UPLO = ‘U’, M <= N. When M = 0, DLANTR is set to zero.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0, and if UPLO = ‘L’, N <= M. When N = 0, DLANTR is set to zero.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The trapezoidal matrix A (A is triangular if M = N). If UPLO = ‘U’, the leading m by n upper trapezoidal part of the array A contains the upper trapezoidal matrix, and the strictly lower triangular part of A is not referenced. If UPLO = ‘L’, the leading m by n lower trapezoidal part of the array A contains the lower trapezoidal matrix, and the strictly upper triangular part of A is not referenced. Note that when DIAG = ‘U’, the diagonal elements of A are not referenced and are assumed to be one.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clantr*, *slantr* and *zlantr*. It also exists with a native C interface as *LAPACKE_dlantr*.

4.17.275 dlanv2

dlanv2 computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form:

```
[ A   B ] = [ CS -SN ] [ AA   BB ] [ CS   SN ]
[ C   D ]   [ SN  CS ] [ CC   DD ] [-SN   CS ]
```

where either 1) CC = 0 so that AA and DD are real eigenvalues of the matrix, or 2) AA = DD and BB*CC < 0, so that AA + or - sqrt(BB*CC) are complex conjugate eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlanv2(A, B, C, D, RT1R, RT1I, RT2R, RT2I, CS, SN)
```

C specification:

```
#include "armpl.h"

void dlanv2_(double *a, double *b, double *c, double *d, double *rt1r,
             double *rt1i, double *rt2r, double *rt2i, double *cs,
             double *sn);
```

Parameters

A Input and output parameter.

A is DOUBLE PRECISION

B Input and output parameter.

B is DOUBLE PRECISION

C Input and output parameter.

C is DOUBLE PRECISION

D Input and output parameter.

D is DOUBLE PRECISION

On entry, the elements of the input matrix. On exit, they are overwritten by the elements of the standardised Schur form.

RT1R Output parameter.

RT1R is DOUBLE PRECISION

RT1I Output parameter.

RT1I is DOUBLE PRECISION

RT2R Output parameter.

RT2R is DOUBLE PRECISION

RT2I Output parameter.

RT2I is DOUBLE PRECISION

The real and imaginary parts of the eigenvalues. If the eigenvalues are a complex conjugate pair, RT1I > 0.

CS Output parameter.

CS is DOUBLE PRECISION

SN Output parameter.

SN is DOUBLE PRECISION

Parameters of the rotation matrix.

Related Information

For this routine in other precisions, please see *slanv2*.

4.17.276 dlapll

Given two column vectors X and Y, let

```
A = ( X Y ).
```

The subroutine first computes the QR factorization of A = Q*R, and then computes the SVD of the 2-by-2 upper triangular matrix R. The smaller singular value of R is returned in SSMIN, which is used as the measurement of the linear dependency of the vectors X and Y.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlapll(N, X, INCX, Y, INCY, SSMIN)
```

C specification:

```
#include "armpl.h"

void dlapll_(const armpl_int_t *n, double *x, const armpl_int_t *incx,
             double *y, const armpl_int_t *incy, double *ssmin);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors X and Y.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array,. dimension (1+(N-1)*INCX) On entry, X contains the N-vector X. On exit, X is overwritten.

INCX Input parameter.

INCX is INTEGER

The increment between successive elements of X. INCX > 0.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array,. dimension (1+(N-1)*INCY) On entry, Y contains the N-vector Y. On exit, Y is overwritten.

INCY Input parameter.

INCY is INTEGER

The increment between successive elements of Y. INCY > 0.

SSMIN Output parameter.

SSMIN is DOUBLE PRECISION

The smallest singular value of the N-by-2 matrix A = (X Y).

Related Information

For this routine in other precisions, please see *clapll*, *slapll* and *zlapll*.

4.17.277 dlapmr

dlapmr rearranges the rows of the M by N matrix X as specified by the permutation K(1),K(2),...,K(M) of the integers 1,...,M. If FORWRD = .TRUE., forward permutation:

```
X(K(I),*) is moved X(I,*) for I = 1,2,...,M.
```

If FORWRD = .FALSE., backward permutation:

```
X(I,*) is moved to X(K(I),*) for I = 1,2,...,M.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlapmr(FORWRD, M, N, X, LDX, K)
```

C specification:

```
#include "armpl.h"

void dlapmr_(const armpl_int_t *forwrd, const armpl_int_t *m,
             const armpl_int_t *n, double *x, const armpl_int_t *ldx,
             armpl_int_t *k);
```

Parameters

FORWRD Input parameter.

FORWRD is LOGICAL

= .TRUE., forward permutation = .FALSE., backward permutation

M Input parameter.

M is INTEGER

The number of rows of the matrix X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix X. N >= 0.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, N). On entry, the M by N matrix X. On exit, X contains the permuted matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X, LDX >= MAX(1, M).

K Input and output parameter.

K is INTEGER array, dimension (M)

On entry, K contains the permutation vector. K is used as internal workspace, but reset to its original value on output.

Related Information

For this routine in other precisions, please see *clapmr*, *slapmr* and *zlapmr*. It also exists with a native C interface as *LAPACKE_dlapmr*.

4.17.278 dlapmt

dlapmt rearranges the columns of the M by N matrix X as specified by the permutation K(1),K(2),...,K(N) of the integers 1,...,N. If FORWRD = .TRUE., forward permutation:

```
X(*,K(J)) is moved X(*,J) for J = 1,2,...,N.
```

If FORWRD = .FALSE., backward permutation:

```
X(*,J) is moved to X(*,K(J)) for J = 1,2,...,N.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlapmt(FORWRD, M, N, X, LDX, K)
```

C specification:

```
#include "armpl.h"

void dlapmt_(const armpl_int_t *forwrd, const armpl_int_t *m,
             const armpl_int_t *n, double *x, const armpl_int_t *ldx,
             armpl_int_t *k);
```

Parameters

FORWRD Input parameter.

FORWRD is LOGICAL

= .TRUE., forward permutation = .FALSE., backward permutation

M Input parameter.

M is INTEGER

The number of rows of the matrix X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix X. N >= 0.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, N). On entry, the M by N matrix X. On exit, X contains the permuted matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X, LDX >= MAX(1, M).

K Input and output parameter.

K is INTEGER array, dimension (N)

On entry, K contains the permutation vector. K is used as internal workspace, but reset to its original value on output.

Related Information

For this routine in other precisions, please see *clapmt*, *slapmt* and *zlapmt*. It also exists with a native C interface as *LAPACKE_dlapmt*.

4.17.279 dlapy2

dlapy2 returns sqrt(x**2+y**2), taking care not to cause unnecessary overflow.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlapy2(X, Y)
```

C specification:

```
#include "armpl.h"

double dlapy2_(const double *x, const double *y);
```

Parameters

X Input parameter.

X is DOUBLE PRECISION

Y Input parameter.

Y is DOUBLE PRECISION

X and Y specify the values x and y.

Related Information

For this routine in other precisions, please see *slapy2*. It also exists with a native C interface as *LAPACKE_dlapy2*.

4.17.280 dlapy3

dlapy3 returns sqrt(x**2+y**2+z**2), taking care not to cause unnecessary overflow.

Syntax

Fortran specification:

```
use armpl_library

double precision function dlapy3(X, Y, Z)
```

C specification:

```
#include "armpl.h"

double dlapy3_(const double *x, const double *y, const double *z);
```

Parameters

X Input parameter.

X is DOUBLE PRECISION

Y Input parameter.

Y is DOUBLE PRECISION

Z Input parameter.

Z is DOUBLE PRECISION

X, Y and Z specify the values x, y and z.

Related Information

For this routine in other precisions, please see *slapy3*. It also exists with a native C interface as *LAPACKE_dlapy3*.

4.17.281 dlaqgb

`dlaqgb` equilibrates a general M by N band matrix A with KL subdiagonals and KU superdiagonals using the row and scaling factors in the vectors R and C.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqgb(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void dlaqgb_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku, double *ab,
             const armpl_int_t *ldab, const double *r, const double *c,
             const double *rowcnd, const double *colcnd, const double *amax,
             char *equed, ... );
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix A. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix A. `N` >= 0.

KL Input parameter.

`KL` is `INTEGER`

The number of subdiagonals within the band of A. `KL` >= 0.

KU Input parameter.

`KU` is `INTEGER`

The number of superdiagonals within the band of A. `KU` >= 0.

AB Input and output parameter.

`AB` is `DOUBLE PRECISION`

`AB` is an array, dimension (`LDAB`, `N`). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array `AB` as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, the equilibrated matrix, in the same storage format as A. See `EQUED` for the form of the equilibrated matrix.

LDAB Input parameter.

`LDAB` is `INTEGER`

The leading dimension of the array `AB`. LDA >= KL+KU+1.

R Input parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). The row scale factors for A.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A.

ROWCND Input parameter.

ROWCND is DOUBLE PRECISION

Ratio of the smallest R(i) to the largest R(i).

COLCND Input parameter.

COLCND is DOUBLE PRECISION

Ratio of the smallest C(i) to the largest C(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C).

Related Information

For this routine in other precisions, please see *claqgb*, *slaqgb* and *zlaqgb*.

4.17.282 dlaqge

dlaqge equilibrates a general M by N matrix A using the row and column scaling factors in the vectors R and C.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqge(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void dlaqge_(const armpl_int_t *m, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, const double *r, const double *c,
             const double *rowcnd, const double *colcnd, const double *amax,
             char *equed, ... );
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M by N matrix A. On exit, the equilibrated matrix. See EQUED for the form of the equilibrated matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

R Input parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). The row scale factors for A.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A.

ROWCND Input parameter.

ROWCND is DOUBLE PRECISION

Ratio of the smallest R(i) to the largest R(i).

COLCND Input parameter.

COLCND is DOUBLE PRECISION

Ratio of the smallest C(i) to the largest C(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C).

Related Information

For this routine in other precisions, please see *claqge*, *slaqge* and *zlaqge*.

4.17.283 dlaqp2

`dlaqp2` computes a QR factorization with column pivoting of the block A(OFFSET+1:M,1:N). The block A(1:OFFSET,1:N) is accordingly pivoted, but not factorized.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqp2(M, N, OFFSET, A, LDA, JPVT, TAU, VN1, VN2, WORK)
```

C specification:

```
#include "armpl.h"

void dlaqp2_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *offset, double *a, const armpl_int_t *lda,
             armpl_int_t *jpvt, double *tau, double *vn1, double *vn2,
             double *work);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

OFFSET Input parameter.

`OFFSET` is `INTEGER`

The number of rows of the matrix `A` that must be pivoted but no factorized. `OFFSET` >= 0.

A Input and output parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). On entry, the M-by-N matrix `A`. On exit, the upper triangle of block A(OFFSET+1:M,1:N) is the triangular factor obtained; the elements in block A(OFFSET+1:M,1:N) below the diagonal, together with the array `TAU`, represent the orthogonal matrix Q as a product of elementary reflectors. Block A(1:OFFSET,1:N) has been accordingly pivoted, but no factorized.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

JPVT Input and output parameter.

`JPVT` is `INTEGER` array, dimension (`N`)

On entry, if JPVT(i) .ne. 0, the i-th column of `A` is permuted to the front of `A`*P (a leading column); if JPVT(i) = 0, the i-th column of `A` is a free column. On exit, if JPVT(i) = k, then the i-th column of `A`*P was the k-th column of `A`.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors.

VN1 Input and output parameter.

VN1 is DOUBLE PRECISION

VN1 is an array, dimension (N). The vector with the partial column norms.

VN2 Input and output parameter.

VN2 is DOUBLE PRECISION

VN2 is an array, dimension (N). The vector with the exact column norms.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

Related Information

For this routine in other precisions, please see *claqp2*, *slaqp2* and *zlaqp2*.

4.17.284 dlaqps

dlaqps computes a step of QR factorization with column pivoting of a real M-by-N matrix A by using Blas-3. It tries to factorize NB columns from A starting from the row OFFSET+1, and updates all of the matrix with Blas-3 xGEMM.

In some cases, due to catastrophic cancellations, it cannot factorize NB columns. Hence, the actual number of factorized columns is returned in KB.

Block A(1:OFFSET,1:N) is accordingly pivoted, but not factorized.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqps(M, N, OFFSET, NB, KB, A, LDA, JPVT, TAU, VN1, VN2, AUXV, F,
                  LDF)
```

C specification:

```
#include "armpl.h"

void dlaqps_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *offset, const armpl_int_t *nb,
             armpl_int_t *kb, double *a, const armpl_int_t *lda,
             armpl_int_t *jpvt, double *tau, double *vn1, double *vn2,
             double *auxv, double *f, const armpl_int_t *ldf);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0

OFFSET Input parameter.

OFFSET is INTEGER

The number of rows of A that have been factorized in previous steps.

NB Input parameter.

NB is INTEGER

The number of columns to factorize.

KB Output parameter.

KB is INTEGER

The number of columns actually factorized.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, block A(OFFSET+1:M,1:KB) is the triangular factor obtained and block A(1:OFFSET,1:N) has been accordingly pivoted, but no factorized. The rest of the matrix, block A(OFFSET+1:M,KB+1:N) has been updated.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

JPVT(I) = K <==> Column K of the full matrix A has been permuted into position I in AP.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (KB). The scalar factors of the elementary reflectors.

VN1 Input and output parameter.

VN1 is DOUBLE PRECISION

VN1 is an array, dimension (N). The vector with the partial column norms.

VN2 Input and output parameter.

VN2 is DOUBLE PRECISION

VN2 is an array, dimension (N). The vector with the exact column norms.

AUXV Input and output parameter.

AUXV is DOUBLE PRECISION

AUXV is an array, dimension (NB). Auxiliar vector.

F Input and output parameter.

F is DOUBLE PRECISION

F is an array, dimension (LDF, NB). Matrix $F^T = L*Y^T *A$.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the array F. LDF >= max(1, N).

Related Information

For this routine in other precisions, please see *claqps*, *slaqps* and *zlaqps*.

4.17.285 dlaqr0

```
DLAQR0 computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**T, where T is an upper quasi-triangular matrix (the
   Schur form), and Z is the orthogonal matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input orthogonal
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the orthogonal matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqr0(WANTT, WANTZ, N, ILO, IHI, H, LDH, WR, WI, ILOZ, IHIZ, Z,
                  LDZ, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlaqr0_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, double *h, const armpl_int_t *ldh,
             double *wr, double *wi, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, double *z, const armpl_int_t *ldz,
             double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1, H(ILO,ILO-1) is zero. ILO and IHI are normally set by a previous call to DGEBAL, and then passed to DGEHRD when the matrix output by DGEBAL is reduced to Hessenberg form. Otherwise, ILO and IHI should be set to 1 and N, respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and WANTT is .TRUE., then H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1).LT.0. If INFO = 0 and WANTT is .FALSE., then the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

This subroutine may explicitly set H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

WR Output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (IHI) .

WI Output parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (IHI). The real and imaginary parts, respectively, of the computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored in WR(ILO:IHI) and WI(ILO:IHI). If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with WI(i) .GT. 0 and WI(i+1) .LT. 0. If WANTT is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with WR(i) = H(i,i) and, if H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) = sqrt(-H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, IHI). If WANTZ is .FALSE., then Z is not referenced. If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the orthogonal Schur factor of H(ILO:IHI,ILO:IHI). (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if WANTZ is .TRUE. then LDZ.GE.MAX(1, IHIZ). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension LWORK. On exit, if LWORK = -1, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient, but LWORK typically as large as 6* N may be required for optimal performance. A workspace query to determine the optimal workspace size is recommended.

If LWORK = -1, then DLAQR0 does a workspace query. In this case, DLAQR0 checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: if INFO = i, DLAQR0 failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and WANT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is an orthogonal matrix. The final value of H is upper Hessenberg and quasi-triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit

(final value of Z(ILO:IHI,ILOZ:IHIZ) = (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

where U is the orthogonal matrix in (*) (regard- less of the value of WANTT.)

If INFO .GT. 0 and WANTZ is .FALSE., then Z is not accessed.

4.17.286 dlaqr1

```
Given a 2-by-2 or 3-by-3 matrix H, DLAQR1 sets v to a
     scalar multiple of the first column of the product

     (*)  K = (H - (sr1 + i*si1)*I)*(H - (sr2 + i*si2)*I)

     scaling to avoid overflows and most underflows. It
     is assumed that either

               1) sr1 = sr2 and si1 = -si2
          or
               2) si1 = si2 = 0.

     This is useful for starting double implicit shift bulges
     in the QR algorithm.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqr1(N, H, LDH, SR1, SI1, SR2, SI2, V)
```

C specification:

```
#include "armpl.h"

void dlaqr1_(const armpl_int_t *n, const double *h, const armpl_int_t *ldh,
             const double *sr1, double *si1, double *sr2, double *si2,
             double *v);
```

Parameters

N Input parameter.

N is INTEGER

Order of the matrix H. N must be either 2 or 3.

H Input parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). The 2-by-2 or 3-by-3 matrix H in (*).

LDH Input parameter.

LDH is INTEGER

The leading dimension of H as declared in the calling procedure. LDH.GE.N

SR1 Input parameter.

SR1 is DOUBLE PRECISION

SI1 Input parameter.

SI1 is DOUBLE PRECISION

SR2 Input parameter.

SR2 is DOUBLE PRECISION

SI2 Input parameter.

SI2 is DOUBLE PRECISION

The shifts in (*).

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension (N). A scalar multiple of the first column of the matrix K in (*).

4.17.287 dlaqr2

```
DLAQR2 is identical to DLAQR3 except that it avoids
   recursion by calling DLAHQR instead of DLAQR4.

   Aggressive early deflation:

   This subroutine accepts as input an upper Hessenberg matrix
   H and performs an orthogonal similarity transformation
   designed to detect and deflate fully converged eigenvalues from
   a trailing principal submatrix.  On output H has been over-
   written by a new Hessenberg matrix that is a perturbation of
   an orthogonal similarity transformation of H.  It is to be
   hoped that the final version of H has many zero subdiagonal
   entries.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqr2(WANTT, WANTZ, N, KTOP, KBOT, NW, H, LDH, ILOZ, IHIZ, Z, LDZ,
                  NS, ND, SR, SI, V, LDV, NH, T, LDT, NV, WV, LDWV, WORK,
                  LWORK)
```

C specification:

```
#include "armpl.h"

void dlaqr2_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ktop,
             const armpl_int_t *kbot, const armpl_int_t *nw, double *h,
             const armpl_int_t *ldh, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, double *z, const armpl_int_t *ldz,
             armpl_int_t *ns, armpl_int_t *nd, double *sr, double *si,
             double *v, const armpl_int_t *ldv, const armpl_int_t *nh,
             double *t, const armpl_int_t *ldt, const armpl_int_t *nv,
             double *wv, const armpl_int_t *ldwv, double *work,
             const armpl_int_t *lwork);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

If .TRUE., then the Hessenberg matrix H is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then only enough of H is updated to preserve the eigenvalues.

WANTZ Input parameter.

WANTZ is LOGICAL

If .TRUE., then the orthogonal matrix Z is updated so so that the orthogonal Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then Z is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix H and (if WANTZ is .TRUE.) the order of the orthogonal matrix Z.

KTOP Input parameter.

KTOP is INTEGER

It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

KBOT Input parameter.

KBOT is INTEGER

It is assumed without a check that either KBOT = N or H(KBOT+1, KBOT)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

NW Input parameter.

NW is INTEGER

Deflation window size. 1 .LE. NW .LE. (KBOT-KTOP+1).

H Input and output parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). On input the initial N-by-N section of H stores the Hessenberg matrix undergoing aggressive early deflation. On output H has been transformed by an orthogonal similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

LDH Input parameter.

LDH is INTEGER

Leading dimension of H just as declared in the calling subroutine. N .LE. LDH

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). IF WANTZ is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ is .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of Z just as declared in the calling subroutine. 1 .LE. LDZ.

NS Output parameter.

NS is INTEGER

The number of unconverged (ie approximate) eigenvalues returned in SR and SI that may be used as shifts by the calling subroutine.

ND Output parameter.

ND is INTEGER

The number of converged eigenvalues uncovered by this subroutine.

SR Output parameter.

SR is DOUBLE PRECISION

SR is an array, dimension (KBOT) .

SI Output parameter.

SI is DOUBLE PRECISION

SI is an array, dimension (KBOT). On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in SR(KBOT-ND-NS+1) through SR(KBOT-ND) and SI(KBOT-ND-NS+1) through SI(KBOT-ND), respectively. The real and imaginary parts of converged eigenvalues are stored in SR(KBOT-ND+1) through SR(KBOT) and SI(KBOT-ND+1) through SI(KBOT), respectively.

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, NW). An NW-by-NW work array.

LDV Input parameter.

LDV is INTEGER

The leading dimension of V just as declared in the calling subroutine. NW .LE. LDV

NH Input parameter.

NH is INTEGER

The number of columns of T. NH.GE.NW.

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, NW) .

LDT Input parameter.

LDT is INTEGER

The leading dimension of T just as declared in the calling subroutine. NW .LE. LDT

NV Input parameter.

NV is INTEGER

The number of rows of work array WV available for workspace. NV.GE.NW.

WV Output parameter.

WV is DOUBLE PRECISION

WV is an array, dimension (LDWV, NW) .

LDWV Input parameter.

LDWV is INTEGER

The leading dimension of W just as declared in the calling subroutine. NW .LE. LDV

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, WORK(1) is set to an estimate of the optimal value of LWORK for the given values of N, NW, KTOP and KBOT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the work array WORK. LWORK = 2*NW suffices, but greater efficiency may result from larger values of LWORK.

If LWORK = -1, then a workspace query is assumed; DLAQR2 only estimates the optimal workspace size for the given values of N, NW, KTOP and KBOT. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

4.17.288 dlaqr3

```
Aggressive early deflation:

   DLAQR3 accepts as input an upper Hessenberg matrix
   H and performs an orthogonal similarity transformation
   designed to detect and deflate fully converged eigenvalues from
   a trailing principal submatrix.  On output H has been over-
   written by a new Hessenberg matrix that is a perturbation of
   an orthogonal similarity transformation of H.  It is to be
   hoped that the final version of H has many zero subdiagonal
   entries.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqr3(WANTT, WANTZ, N, KTOP, KBOT, NW, H, LDH, ILOZ, IHIZ, Z, LDZ,
                  NS, ND, SR, SI, V, LDV, NH, T, LDT, NV, WV, LDWV, WORK,
                  LWORK)
```

C specification:

```
#include "armpl.h"

void dlaqr3_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ktop,
             const armpl_int_t *kbot, const armpl_int_t *nw, double *h,
             const armpl_int_t *ldh, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, double *z, const armpl_int_t *ldz,
             armpl_int_t *ns, armpl_int_t *nd, double *sr, double *si,
             double *v, const armpl_int_t *ldv, const armpl_int_t *nh,
             double *t, const armpl_int_t *ldt, const armpl_int_t *nv,
             double *wv, const armpl_int_t *ldwv, double *work,
             const armpl_int_t *lwork);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

If .TRUE., then the Hessenberg matrix H is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then only enough of H is updated to preserve the eigenvalues.

WANTZ Input parameter.

WANTZ is LOGICAL

If .TRUE., then the orthogonal matrix Z is updated so so that the orthogonal Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then Z is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix H and (if WANTZ is .TRUE.) the order of the orthogonal matrix Z.

KTOP Input parameter.

KTOP is INTEGER

It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

KBOT Input parameter.

KBOT is INTEGER

It is assumed without a check that either KBOT = N or H(KBOT+1, KBOT)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

NW Input parameter.

NW is INTEGER

Deflation window size. 1 .LE. NW .LE. (KBOT-KTOP+1).

H Input and output parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). On input the initial N-by-N section of H stores the Hessenberg matrix undergoing aggressive early deflation. On output H has been transformed by an orthogonal similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

LDH Input parameter.

LDH is INTEGER

Leading dimension of H just as declared in the calling subroutine. N .LE. LDH

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). IF WANTZ is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ is .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of Z just as declared in the calling subroutine. 1 .LE. LDZ.

NS Output parameter.

NS is INTEGER

The number of unconverged (ie approximate) eigenvalues returned in SR and SI that may be used as shifts by the calling subroutine.

ND Output parameter.

ND is INTEGER

The number of converged eigenvalues uncovered by this subroutine.

SR Output parameter.

SR is DOUBLE PRECISION

SR is an array, dimension (KBOT) .

SI Output parameter.

SI is DOUBLE PRECISION

SI is an array, dimension (KBOT). On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in SR(KBOT-ND-NS+1) through SR(KBOT-ND) and SI(KBOT-ND-NS+1) through SI(KBOT-ND), respectively. The real and imaginary parts of converged eigenvalues are stored in SR(KBOT-ND+1) through SR(KBOT) and SI(KBOT-ND+1) through SI(KBOT), respectively.

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, NW). An NW-by-NW work array.

LDV Input parameter.

LDV is INTEGER

The leading dimension of V just as declared in the calling subroutine. NW .LE. LDV

NH Input parameter.

NH is INTEGER

The number of columns of T. NH.GE.NW.

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, NW) .

LDT Input parameter.

LDT is INTEGER

The leading dimension of T just as declared in the calling subroutine. NW .LE. LDT

NV Input parameter.

NV is INTEGER

The number of rows of work array WV available for workspace. NV.GE.NW.

WV Output parameter.

WV is DOUBLE PRECISION

WV is an array, dimension (LDWV, NW) .

LDWV Input parameter.

LDWV is INTEGER

The leading dimension of W just as declared in the calling subroutine. NW .LE. LDV

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, WORK(1) is set to an estimate of the optimal value of LWORK for the given values of N, NW, KTOP and KBOT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the work array WORK. LWORK = 2*NW suffices, but greater efficiency may result from larger values of LWORK.

If LWORK = -1, then a workspace query is assumed; DLAQR3 only estimates the optimal workspace size for the given values of N, NW, KTOP and KBOT. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

4.17.289 dlaqr4

```
DLAQR4 implements one level of recursion for DLAQR0.
   It is a complete implementation of the small bulge multi-shift
   QR algorithm.  It may be called by DLAQR0 and, for large enough
   deflation window size, it may be called by DLAQR3.  This
   subroutine is identical to DLAQR0 except that it calls DLAQR2
   instead of DLAQR3.

   DLAQR4 computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**T, where T is an upper quasi-triangular matrix (the
   Schur form), and Z is the orthogonal matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input orthogonal
```

(continues on next page)

(continued from previous page)

```
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the orthogonal matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqr4(WANTT, WANTZ, N, ILO, IHI, H, LDH, WR, WI, ILOZ, IHIZ, Z,
                  LDZ, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlaqr4_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, double *h, const armpl_int_t *ldh,
             double *wr, double *wi, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, double *z, const armpl_int_t *ldz,
             double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1, H(ILO,ILO-1) is zero. ILO and IHI are normally set by a previous call to DGEBAL, and then passed to DGEHRD when the matrix output by DGEBAL is reduced to Hessenberg form. Otherwise, ILO and IHI should be set to 1 and N, respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and WANTT is .TRUE., then H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur

form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1).LT.0. If INFO = 0 and WANTT is .FALSE., then the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

This subroutine may explicitly set H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

WR Output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (IHI) .

WI Output parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (IHI). The real and imaginary parts, respectively, of the computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored in WR(ILO:IHI) and WI(ILO:IHI). If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with WI(i) .GT. 0 and WI(i+1) .LT. 0. If WANTT is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with WR(i) = H(i,i) and, if H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) = sqrt(-H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, IHI). If WANTZ is .FALSE., then Z is not referenced. If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the orthogonal Schur factor of H(ILO:IHI,ILO:IHI). (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if WANTZ is .TRUE. then LDZ.GE.MAX(1, IHIZ). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension LWORK. On exit, if LWORK = -1, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient, but LWORK typically as large as 6* N may be required for optimal performance. A workspace query to determine the optimal workspace size is recommended.

If LWORK = -1, then DLAQR4 does a workspace query. In this case, DLAQR4 checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: if INFO = i, DLAQR4 failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and WANT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is a orthogonal matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit

(final value of Z(ILO:IHI,ILOZ:IHIZ) = (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

where U is the orthogonal matrix in (*) (regard- less of the value of WANTT.)

If INFO .GT. 0 and WANTZ is .FALSE., then Z is not accessed.

```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

WANTT = .true. if the quasi-triangular Schur factor is being computed. WANTT is set to .false. otherwise.

WANTZ Input parameter.

WANTZ is LOGICAL

WANTZ = .true. if the orthogonal Schur factor is being computed. WANTZ is set to .false. otherwise.

KACC22 Input parameter.

KACC22 is INTEGER with value 0, 1, or 2.

Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: DLAQR5 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: DLAQR5 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: DLAQR5 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.

N Input parameter.

N is INTEGER

N is the order of the Hessenberg matrix H upon which this subroutine operates.

KTOP Input parameter.

KTOP is INTEGER

KBOT Input parameter.

KBOT is INTEGER

These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either KTOP = 1 or H(KTOP,KTOP-1) = 0 and either KBOT = N or H(KBOT+1, KBOT) = 0.

NSHFTS Input parameter.

NSHFTS is INTEGER

NSHFTS gives the number of simultaneous shifts. NSHFTS must be positive and even.

SR Input and output parameter.

SR is DOUBLE PRECISION

SR is an array, dimension (NSHFTS) .

SI Input and output parameter.

SI is DOUBLE PRECISION

SI is an array, dimension (NSHFTS). SR contains the real parts and SI contains the imaginary parts of the NSHFTS shifts of origin that define the multi-shift QR sweep. On output SR and SI may be reordered.

H Input and output parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). On input H contains a Hessenberg matrix. On output a multi-shift QR sweep with shifts SR(J)+i*SI(J) is applied to the isolated diagonal block in rows and columns KTOP through KBOT.

LDH Input parameter.

LDH is INTEGER

LDH is the leading dimension of H just as declared in the calling procedure. LDH.GE.MAX(1, N).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, IHIZ). If WANTZ = .TRUE., then the QR Sweep orthogonal similarity transformation is accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ = .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

LDA is the leading dimension of Z just as declared in the calling procedure. LDZ.GE.N.

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV,NSHFTS/2) .

LDV Input parameter.

LDV is INTEGER

LDV is the leading dimension of V as declared in the calling procedure. LDV.GE.3.

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU,3*NSHFTS-3) .

LDU Input parameter.

LDU is INTEGER

LDU is the leading dimension of U just as declared in the in the calling subroutine. LDU.GE.3*NSHFTS-3.

NH Input parameter.

NH is INTEGER

NH is the number of columns in array WH available for workspace. NH.GE.1.

WH Output parameter.

WH is DOUBLE PRECISION

WH is an array, dimension (LDWH, NH) .

LDWH Input parameter.

LDWH is INTEGER

Leading dimension of WH just as declared in the calling procedure. LDWH.GE.3*NSHFTS-3.

NV Input parameter.

NV is INTEGER

NV is the number of rows in WV agailable for workspace. NV.GE.1.

WV Output parameter.

WV is DOUBLE PRECISION

WV is an array, dimension (LDWV,3*NSHFTS-3) .

LDWV Input parameter.

LDWV is INTEGER

LDWV is the leading dimension of WV as declared in the in the calling subroutine. LDWV.GE.NV.

4.17.291 dlaqsb

dlaqsb equilibrates a symmetric band matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqsb(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void dlaqsb_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             double *ab, const armpl_int_t *ldab, const double *s,
             const double *scond, const double *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is DOUBLE PRECISION

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqsb*, *slaqsb* and *zlaqsb*.

4.17.292 dlaqsp

dlaqsp equilibrates a symmetric matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqsp(UPLO, N, AP, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void dlaqsp_(const char *uplo, const armpl_int_t *n, double *ap,
             const double *s, const double *scond, const double *amax,
             char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the equilibrated matrix: diag(S) * A * diag(S), in the same storage format as A.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is DOUBLE PRECISION

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqsp*, *slaqsp* and *zlaqsp*.

4.17.293 dlaqsy

dlaqsy equilibrates a symmetric matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqsy(UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void dlaqsy_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, const double *s, const double *scond,
             const double *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if EQUED = 'Y', the equilibrated matrix: diag(S) * A * diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is DOUBLE PRECISION

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqsy*, *slaqsy* and *zlaqsy*.

4.17.294 dlaqtr

`dlaqtr` solves the real quasi-triangular system

```
op(T)*p = scale*c,                 if LREAL = .TRUE.
```

or the complex quasi-triangular systems

```
op(T + iB)*(p+iq) = scale*(c+id),  if LREAL = .FALSE.
```

in real arithmetic, where T is upper quasi-triangular. If LREAL = .FALSE., then the first diagonal block of T must be 1 by 1, B is the specially structured matrix

```
B = [ b(1) b(2) ... b(n) ]
    [       w            ]
    [           w        ]
    [               .    ]
    [                   w ]
```

op(A) = A or A^T , A^T denotes the transpose of matrix A.

On input, X = [c]. On output, X = [p].

```
[ d ]                  [ q ]
```

This subroutine is designed for the condition number estimation in routine DTRSNA.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaqtr(LTRAN, LREAL, N, T, LDT, B, W, SCALE, X, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlaqtr_(const armpl_int_t *ltran, const armpl_int_t *lreal,
             const armpl_int_t *n, const double *t, const armpl_int_t *ldt,
             const double *b, const double *w, double *scale, double *x,
             double *work, armpl_int_t *info);
```

Parameters

LTRAN Input parameter.

LTRAN is LOGICAL

On entry, LTRAN specifies the option of conjugate transpose: = .FALSE., op(T+i*B) = T+i*B, = .TRUE., op(T+i*B) = $(T+i*B)^T$.

LREAL Input parameter.

L‘‘REAL‘‘ is LOGICAL

On entry, L‘‘REAL‘‘ specifies the input matrix structure: = .FALSE., the input is complex = .TRUE., the input is real

N Input parameter.

N is INTEGER

On entry, N specifies the order of T+i*B. N >= 0.

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). On entry, T contains a matrix in Schur canonical form. If L‘‘REAL‘‘ = .FALSE., then the first diagonal block of T mu be 1 by 1.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the matrix T. LDT >= max(1, N).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (N). On entry, B contains the elements to form the matrix B as described above. If L‘‘REAL‘‘ = .TRUE., B is not referenced.

W Input parameter.

W is DOUBLE PRECISION

On entry, W is the diagonal element of the matrix B. If L‘‘REAL‘‘ = .TRUE., W is not referenced.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

On exit, SCALE is the scale factor.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (2*N). On entry, X contains the right hand side of the system. On exit, X is overwritten by the solution.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

On exit, INFO is set to 0: successful exit. 1: the some diagonal 1 by 1 block has been perturbed by a small number SMIN to keep nonsingularity. 2: the some diagonal 2 by 2 block has been perturbed by a small number in DLALN2 to keep nonsingularity. NOTE: In the interests of speed, this routine does not check the inputs for errors.

Related Information

For this routine in other precisions, please see *slaqtr*.

4.17.295 dlar1v

dlar1v computes the (scaled) r-th column of the inverse of the sumbmatrix in rows B1 through BN of the tridiagonal matrix L D L^T - sigma I. When sigma is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, r corresponds to the index where the eigenvector is largest in magnitude. The following steps

accomplish this computation : (a) Stationary qd transform, L D L^T - sigma I = L(+) D(+) $L(+)^T$, (b) Progressive qd transform, L D L^T - sigma I = U(-) D(-) $U(-)^T$, (c) Computation of the diagonal elements of the inverse of

```
L D L**T - sigma I by combining the above transforms, and choosing
r as the index where the diagonal of the inverse is (one of the)
largest in magnitude.
```

(d) Computation of the (scaled) r-th column of the inverse using the

```
twisted factorization obtained by combining the top part of the
the stationary and the bottom part of the progressive transform.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlar1v(N, B1, BN, LAMBDA, D, L, LD, LLD, PIVMIN, GAPTOL, Z, WANTNC,
                  NEGCNT, ZTZ, MINGMA, R, ISUPPZ, NRMINV, RESID, RQCORR,
                  WORK)
```

C specification:

```
#include "armpl.h"

void dlar1v_(const armpl_int_t *n, const armpl_int_t *b1,
             const armpl_int_t *bn, const double *lambda, const double *d,
             const double *l, const double *ld, const double *lld,
             const double *pivmin, const double *gaptol, double *z,
             const armpl_int_t *wantnc, armpl_int_t *negcnt, double *ztz,
             double *mingma, armpl_int_t *r, armpl_int_t *isuppz,
             double *nrminv, double *resid, double *rqcorr, double *work);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix L D L^T .

B1 Input parameter.

B1 is INTEGER

First index of the submatrix of L D L^T .

BN Input parameter.

BN is INTEGER

Last index of the submatrix of L D L^T .

LAMBDA Input parameter.

LAMBDA is DOUBLE PRECISION

The shift. In order to compute an accurate eigenvector, LAMBDA should be a good approximation to an eigenvalue of L D L^T .

L Input parameter.

L is DOUBLE PRECISION

L is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal matrix L, in elements 1 to N-1.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D.

LD Input parameter.

LD is DOUBLE PRECISION

LD is an array, dimension (N-1). The n-1 elements L(i)*D(i).

LLD Input parameter.

LLD is DOUBLE PRECISION

LLD is an array, dimension (N-1). The n-1 elements L(i)*L(i)*D(i).

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot in the Sturm sequence.

GAPTOL Input parameter.

GAPTOL is DOUBLE PRECISION

Tolerance that indicates when eigenvector entries are negligible w.r.t. their contribution to the residual.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (N). On input, all entries of Z must be set to 0. On output, Z contains the (scaled) r-th column of the inverse. The scaling is such that Z(R) equals 1.

WANTNC Input parameter.

WANTNC is LOGICAL

Specifies whether NEGCNT has to be computed.

NEGCNT Output parameter.

NEGCNT is INTEGER

If WANTNC is .TRUE. then NEGCNT = the number of pivots < pivmin in the matrix factorization L D L^T , and NEGCNT = -1 otherwise.

ZTZ Output parameter.

ZTZ is DOUBLE PRECISION

The square of the 2-norm of Z.

MINGMA Output parameter.

MINGMA is DOUBLE PRECISION

The reciprocal of the largest (in magnitude) diagonal element of the inverse of L D L^T - sigma I.

R Input and output parameter.

R is INTEGER

The twist index for the twisted factorization used to compute Z. On input, 0 <= R <= N. If R is input as 0, R is set to the index where (L D L^T - sigma I)^{-1} is largest in magnitude. If 1 <= R <= N, R is unchanged. On output, R contains the twist index used to compute Z. Ideally, R designates the position of the maximum entry in the eigenvector.

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2)

The support of the vector in Z, i.e., the vector Z is nonzero only in elements ISUPPZ(1) through ISUPPZ(2).

NRMINV Output parameter.

NRMINV is DOUBLE PRECISION

NRMINV = 1/SQRT(ZTZ)

RESID Output parameter.

RESID is DOUBLE PRECISION

The residual of the FP vector. RESID = ABS(MINGMA)/SQRT(ZTZ)

RQCORR Output parameter.

RQCORR is DOUBLE PRECISION

The Rayleigh Quotient correction to LAMBDA. RQCORR = MINGMA*TMP

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

Related Information

For this routine in other precisions, please see *clar1v*, *slar1v* and *zlar1v*.

4.17.296 dlar2v

dlar2v applies a vector of real plane rotations from both sides to a sequence of 2-by-2 real symmetric matrices, defined by the elements of the vectors x, y and z. For i = 1,2,...,n

```
( x(i)  z(i) ) := (  c(i)  s(i) ) ( x(i)  z(i) ) ( c(i) -s(i) )
( z(i)  y(i) )    ( -s(i)  c(i) ) ( z(i)  y(i) ) ( s(i)  c(i) )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlar2v(N, X, Y, Z, INCX, C, S, INCC)
```

C specification:

```
#include "armpl.h"

void dlar2v_(const armpl_int_t *n, double *x, double *y, double *z,
             const armpl_int_t *incx, const double *c, const double *s,
             const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be applied.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array,. dimension (1+(N-1)*INCX) The vector x.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array,. dimension (1+(N-1)*INCX) The vector y.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array,. dimension (1+(N-1)*INCX) The vector z.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X, Y and Z. INCX > 0.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (1+(N-1)*INCC). The sines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C and S. INCC > 0.

Related Information

For this routine in other precisions, please see *clar2v*, *slar2v* and *zlar2v*.

4.17.297 dlarf

dlarf applies a real elementary reflector H to a real m by n matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**T
```

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarf(SIDE, M, N, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void dlarf_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
            const double *v, const armpl_int_t *incv, const double *tau,
            double *c, const armpl_int_t *ldc, double *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension. (1 + (M-1)*abs(INCV)) if SIDE = 'L' or (1 + (N-1)*abs(INCV)) if SIDE = 'R' The vector v in the representation of H. V is not used if TAU = 0.

INCV Input parameter.

INCV is INTEGER

The increment between elements of v. INCV <> 0.

TAU Input parameter.

TAU is DOUBLE PRECISION

The value tau in the representation of H.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R'

Related Information

For this routine in other precisions, please see *clarf*, *slarf* and *zlarf*.

4.17.298 dlarfb

dlarfb applies a real block reflector H or its transpose H^T to a real m by n matrix C, from either the left or the right.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarfb(SIDE, TRANS, DIRECT, STOREV, M, N, K, V, LDV, T, LDT, C,
                  LDC, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void dlarfb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const double *v, const armpl_int_t *ldv,
             const double *t, const armpl_int_t *ldt, double *c,
             const armpl_int_t *ldc, double *work, const armpl_int_t *ldwork,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^T from the Left = 'R': apply H or H^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'T': apply H^T (Transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columnwise = 'R': Rowwise

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

K Input parameter.

K is INTEGER

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, M) if STOREV = 'R' and SIDE = 'L' (LDV, N) if STOREV = 'R' and SIDE = 'R' The matrix V. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C' and SIDE = 'L', LDV >= max(1, M); if STOREV = 'C' and SIDE = 'R', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, K). The triangular k by k matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by H* C or H^T * C or C*H or C*H^T .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LDWORK, K) .

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1, N); if SIDE = 'R', LDWORK >= max(1, M).

Related Information

For this routine in other precisions, please see *clarfb*, *slarfb* and *zlarfb*. It also exists with a native C interface as *LAPACKE_dlarfb*.

4.17.299 dlarfg

`dlarfg` generates a real elementary reflector H of order n, such that

```
H * ( alpha ) = ( beta ),   H**T * H = I.
    (   x   )   (   0  )
```

where alpha and beta are scalars, and x is an (n-1)-element real vector. H is represented in the form

```
H = I - tau * ( 1 ) * ( 1 v**T ) ,
              ( v )
```

where tau is a real scalar and v is a real (n-1)-element vector.

If the elements of x are all zero, then tau = 0 and H is taken to be the unit matrix.

Otherwise 1 <= tau <= 2.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarfg(N, ALPHA, X, INCX, TAU)
```

C specification:

```
#include "armpl.h"

void dlarfg_(const armpl_int_t *n, double *alpha, double *x,
             const armpl_int_t *incx, double *tau);
```

Parameters

N Input parameter.

N is INTEGER

The order of the elementary reflector.

ALPHA Input and output parameter.

ALPHA is DOUBLE PRECISION

On entry, the value alpha. On exit, it is overwritten with the value beta.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension. (1+(N-2)*abs(INCX)) On entry, the vector x. On exit, it is overwritten with the vector v.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

TAU Output parameter.

TAU is DOUBLE PRECISION

The value tau.

Related Information

For this routine in other precisions, please see *clarfg*, *slarfg* and *zlarfg*. It also exists with a native C interface as *LAPACKE_dlarfg*.

4.17.300 dlarfgp

dlarfgp generates a real elementary reflector H of order n, such that

```
H * ( alpha ) = ( beta ),   H**T * H = I.
    (   x   )   (   0  )
```

where alpha and beta are scalars, beta is non-negative, and x is an (n-1)-element real vector. H is represented in the form

```
H = I - tau * ( 1 ) * ( 1 v**T ) ,
              ( v )
```

where tau is a real scalar and v is a real (n-1)-element vector.

If the elements of x are all zero, then tau = 0 and H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarfgp(N, ALPHA, X, INCX, TAU)
```

C specification:

```
#include "armpl.h"

void dlarfgp_(const armpl_int_t *n, double *alpha, double *x,
              const armpl_int_t *incx, double *tau);
```

Parameters

N Input parameter.

N is INTEGER

The order of the elementary reflector.

ALPHA Input and output parameter.

ALPHA is DOUBLE PRECISION

On entry, the value alpha. On exit, it is overwritten with the value beta.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension. (1+(N-2)*abs(INCX)) On entry, the vector x. On exit, it is overwritten with the vector v.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

TAU Output parameter.

TAU is DOUBLE PRECISION

The value tau.

Related Information

For this routine in other precisions, please see *clarfgp*, *slarfgp* and *zlarfgp*.

4.17.301 dlarft

dlarft forms the triangular factor T of a real block reflector H of order n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

```
H  =  I - V * T * V**T
```

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

```
H  =  I - V**T * T * V
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarft(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

C specification:

```
#include "armpl.h"

void dlarft_(const char *direct, const char *storev, const armpl_int_t *n,
             const armpl_int_t *k, const double *v, const armpl_int_t *ldv,
             const double *tau, double *t, const armpl_int_t *ldt, ... );
```

Parameters

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details): = 'C': columnwise = 'R': rowwise

N Input parameter.

N is INTEGER

The order of the block reflector H. N >= 0.

K Input parameter.

K is INTEGER

The order of the triangular factor T (= the number of elementary reflectors). K >= 1.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, N) if STOREV = 'R' The matrix V. See further details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, K). The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

Related Information

For this routine in other precisions, please see *clarft*, *slarft* and *zlarft*. It also exists with a native C interface as *LAPACKE_dlarft*.

4.17.302 dlarfx

dlarfx applies a real elementary reflector H to a real m by n matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**T
```

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix

This version uses inline code if H has order < 11.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarfx(SIDE, M, N, V, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void dlarfx_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
             const double *v, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension (M) if SIDE = 'L'. or (N) if SIDE = 'R' The vector v in the representation of H.

TAU Input parameter.

TAU is DOUBLE PRECISION

The value tau in the representation of H.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDA >= (1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R' WORK is not referenced if H has order < 11.

Related Information

For this routine in other precisions, please see *clarfx*, *slarfx* and *zlarfx*. It also exists with a native C interface as *LAPACKE_dlarfx*.

4.17.303 dlarfy

`dlarfy` applies an elementary reflector, or Householder matrix, H, to an n x n symmetric matrix C, from both the left and the right.

H is represented in the form

```
H = I - tau * v * v'
```

where tau is a scalar and v is a vector.

If tau is zero, then H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarfy(UPLO, N, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void dlarfy_(const char *uplo, const armpl_int_t *n, const double *v,
             const armpl_int_t *incv, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the upper or lower triangular part of the symmetric matrix `C` is stored. = '`U`': Upper triangle = '`L`': Lower triangle

N Input parameter.

`N` is `INTEGER`

The number of rows and columns of the matrix `C`. `N` >= 0.

V Input parameter.

`V` is `DOUBLE PRECISION`

`V` is an array, dimension. (1 + (N-1)*abs(`INCV`)) The vector v as described above.

INCV Input parameter.

`INCV` is `INTEGER`

The increment between successive elements of v. `INCV` must not be zero.

TAU Input parameter.

TAU is DOUBLE PRECISION

The value tau as described above.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the matrix C. On exit, C is overwritten by H * C * H'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

Related Information

For this routine in other precisions, please see *clarfy*, *slarfy* and *zlarfy*.

4.17.304 dlargv

dlargv generates a vector of real plane rotations, determined by elements of the real vectors x and y. For i = 1,2,...,n

```
(  c(i)  s(i) ) ( x(i) ) = ( a(i) )
( -s(i)  c(i) ) ( y(i) ) = (   0  )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlargv(N, X, INCX, Y, INCY, C, INCC)
```

C specification:

```
#include "armpl.h"

void dlargv_(const armpl_int_t *n, double *x, const armpl_int_t *incx,
             double *y, const armpl_int_t *incy, double *c,
             const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be generated.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array,. dimension (1+(N-1)*INCX) On entry, the vector x. On exit, x(i) is overwritten by a(i), for i = 1,. . . ,n.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array,. dimension (1+(N-1)*INCY) On entry, the vector y. On exit, the sines of the plane rotations.

INCY Input parameter.

INCY is INTEGER

The increment between elements of Y. INCY > 0.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C. INCC > 0.

Related Information

For this routine in other precisions, please see *clargv*, *slargv* and *zlargv*.

4.17.305 dlarnv

dlarnv returns a vector of n random real numbers from a uniform or normal distribution.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarnv(IDIST, ISEED, N, X)
```

C specification:

```
#include "armpl.h"

void dlarnv_(const armpl_int_t *idist, armpl_int_t *iseed,
             const armpl_int_t *n, double *x);
```

Parameters

IDIST Input parameter.

IDIST is INTEGER

Specifies the distribution of the random numbers: = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1)

ISEED Input and output parameter.

ISEED is INTEGER array, dimension (4)

On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and ISEED(4) must be odd. On exit, the seed is updated.

N Input parameter.

N is INTEGER

The number of random numbers to be generated.

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). The generated random numbers.

Related Information

For this routine in other precisions, please see *clarnv*, *slarnv* and *zlarnv*. It also exists with a native C interface as *LAPACKE_dlarnv*.

4.17.306 dlarra

Compute the splitting points with threshold SPLTOL. dlarra sets any "small" off-diagonal elements to zero.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarra(N, D, E, E2, SPLTOL, TNRM, NSPLIT, ISPLIT, INFO)
```

C specification:

```
#include "armpl.h"

void dlarra_(const armpl_int_t *n, const double *d, double *e, double *e2,
             const double *spltol, const double *tnrm, armpl_int_t *nsplit,
             armpl_int_t *isplit, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N > 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, the first (N-1) entries contain the subdiagonal elements of the tridiagonal matrix T; E(N) need not be set. On exit, the entries E(ISPLIT(I)), 1 <= I <= NSPLIT, are set to zero, the other entries of E are untouched.

E2 Input and output parameter.

E2 is DOUBLE PRECISION

E2 is an array, dimension (N). On entry, the first (N-1) entries contain the SQUARES of the subdiagonal elements of the tridiagonal matrix T; E2(N) need not be set. On exit, the entries E2(ISPLIT(I)), 1 <= I <= NSPLIT, have been set to zero

SPLTOL Input parameter.

SPLTOL is DOUBLE PRECISION

The threshold for splitting. Two criteria can be used: SPLTOL<0 : criterion based on absolute off-diagonal value SPLTOL>0 : criterion that preserves relative accuracy

TNRM Input parameter.

TNRM is DOUBLE PRECISION

The norm of the matrix.

NSPLIT Output parameter.

NSPLIT is INTEGER

The number of blocks T splits into. 1 <= NSPLIT <= N.

ISPLIT Output parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

Related Information

For this routine in other precisions, please see *slarra*.

4.17.307 dlarrb

Given the relatively robust representation(RRR) L D L^T, dlarrb does "limited" bisection to refine the eigenvalues of L D L^T, W(IFIRST-OFFSET) through W(ILAST-OFFSET), to more accuracy. Initial guesses for these eigenvalues are input in W, the corresponding estimate of the error in these guesses and their gaps are input in WERR and WGAP, respectively. During bisection, intervals [left, right] are maintained by storing their mid-points and semi-widths in the arrays W and WERR respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarrb(N, D, LLD, IFIRST, ILAST, RTOL1, RTOL2, OFFSET, W, WGAP,
                  WERR, WORK, IWORK, PIVMIN, SPDIAM, TWIST, INFO)
```

C specification:

```
#include "armpl.h"

void dlarrb_(const armpl_int_t *n, const double *d, const double *lld,
             const armpl_int_t *ifirst, const armpl_int_t *ilast,
             const double *rtol1, const double *rtol2,
             const armpl_int_t *offset, double *w, double *wgap, double *werr,
             double *work, armpl_int_t *iwork, const double *pivmin,
             const double *spdiam, const armpl_int_t *twist,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The N diagonal elements of the diagonal matrix D.

LLD Input parameter.

LLD is DOUBLE PRECISION

LLD is an array, dimension (N-1). The (N-1) elements L(i)*L(i)*D(i).

IFIRST Input parameter.

IFIRST is INTEGER

The index of the first eigenvalue to be computed.

ILAST Input parameter.

ILAST is INTEGER

The index of the last eigenvalue to be computed.

RTOL1 Input parameter.

RTOL1 is DOUBLE PRECISION

RTOL2 Input parameter.

RTOL2 is DOUBLE PRECISION

Tolerance for the convergence of the bisection intervals. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|)) where GAP is the (estimated) distance to the nearest eigenvalue.

OFFSET Input parameter.

OFFSET is INTEGER

Offset for the arrays W, WGAP and WERR, i.e., the IFIRST-OFFSET through ILAST-OFFSET elements of these arrays are to be used.

W Input and output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On input, W(IFIRST-OFFSET) through W(ILAST-OFFSET) are estimates of the eigenvalues of L D L^T indexed IFIRST through ILAST. On output, these estimates are refined.

WGAP Input and output parameter.

WGAP is DOUBLE PRECISION

WGAP is an array, dimension (N-1). On input, the (estimated) gaps between consecutive eigenvalues of L D L^T, i.e., WGAP(I-OFFSET) is the gap between eigenvalues I and I+1. Note that if IFIRST.EQ.ILAST then WGAP(IFIRST-OFFSET) must be set to ZERO. On output, these gaps are refined.

WERR Input and output parameter.

WERR is DOUBLE PRECISION

WERR is an array, dimension (N). On input, WERR(IFIRST-OFFSET) through WERR(ILAST-OFFSET) are the errors in the estimates of the corresponding elements in W. On output, these errors are refined.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N). Workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (2*N)

Workspace.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot in the Sturm sequence.

SPDIAM Input parameter.

SPDIAM is DOUBLE PRECISION

The spectral diameter of the matrix.

TWIST Input parameter.

TWIST is INTEGER

The twist index for the twisted factorization that is used for the negcount. TWIST = N: Compute negcount from L D L^T - LAMBDA I = L+ D+ L+^T TWIST = 1: Compute negcount from L D L^T - LAMBDA I = U- D- U-^T TWIST = R: Compute negcount from L D L^T - LAMBDA I = N(r) D(r) N(r)

INFO Output parameter.

INFO is INTEGER

Error flag.

Related Information

For this routine in other precisions, please see *slarrb*.

4.17.308 dlarrc

Find the number of eigenvalues of the symmetric tridiagonal matrix T that are in the interval (VL,VU] if JOBT = 'T', and of L D L^T if JOBT = 'L'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarrc(JOBT, N, VL, VU, D, E, PIVMIN, EIGCNT, LCNT, RCNT, INFO)
```

C specification:

```
#include "armpl.h"

void dlarrc_(const char *jobt, const armpl_int_t *n, const double *vl,
             const double *vu, const double *d, const double *e,
             const double *pivmin, armpl_int_t *eigcnt, armpl_int_t *lcnt,
             armpl_int_t *rcnt, armpl_int_t *info, ... );
```

Parameters

JOBT Input parameter.

JOBT is CHARACTER*1

= 'T': Compute Sturm count for matrix T. = 'L': Compute Sturm count for matrix L D L^T.

N Input parameter.

N is INTEGER

The order of the matrix. N > 0.

VL Input parameter.

VL is DOUBLE PRECISION

The lower bound for the eigenvalues.

VU Input parameter.

VU is DOUBLE PRECISION

The upper bound for the eigenvalues.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). JOBT = 'T': The N diagonal elements of the tridiagonal matrix T. JOBT = 'L': The N diagonal elements of the diagonal matrix D.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). JOBT = 'T': The N-1 offdiagonal elements of the matrix T. JOBT = 'L': The N-1 offdiagonal elements of the matrix L.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot in the Sturm sequence for T.

EIGCNT Output parameter.

EIGCNT is INTEGER

The number of eigenvalues of the symmetric tridiagonal matrix T that are in the interval (VL,VU]

LCNT Output parameter.

LCNT is INTEGER

RCNT Output parameter.

RCNT is INTEGER

The left and right negcounts of the interval.

INFO Output parameter.

INFO is INTEGER

Related Information

For this routine in other precisions, please see *slarrc*.

4.17.309 dlarrd

dlarrd computes the eigenvalues of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from DSTEMR. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarrd(RANGE, ORDER, N, VL, VU, IL, IU, GERS, RELTOL, D, E, E2,
                  PIVMIN, NSPLIT, ISPLIT, M, W, WERR, WL, WU, IBLOCK, INDEXW,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlarrd_(const char *range, const char *order, const armpl_int_t *n,
             const double *vl, const double *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const double *gers, const double *reltol,
             const double *d, const double *e, const double *e2,
             const double *pivmin, const armpl_int_t *nsplit,
             const armpl_int_t *isplit, armpl_int_t *m, double *w,
             double *werr, double *wl, double *wu, armpl_int_t *iblock,
             armpl_int_t *indexw, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found. = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

ORDER Input parameter.

ORDER is CHARACTER*1

= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see IBLOCK, ISPLIT) and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix T. N >= 0.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

GERS Input parameter.

GERS is DOUBLE PRECISION

GERS is an array, dimension (2*N). The N Gerschgorin intervals (the i-th Gerschgorin interval is (GERS(2*i-1), GERS(2*i)).

RELTOL Input parameter.

RELTOL is DOUBLE PRECISION

The minimum relative width of an interval. When an interval is narrower than RELTOL times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the tridiagonal matrix T.

E2 Input parameter.

E2 is DOUBLE PRECISION

E2 is an array, dimension (N-1). The (n-1) squared off-diagonal elements of the tridiagonal matrix T.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot allowed in the Sturm sequence for T.

NSPLIT Input parameter.

NSPLIT is INTEGER

The number of diagonal blocks in the matrix T. 1 <= NSPLIT <= N.

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N. (Only the first NSPLIT elements will actually be used, but since the user cannot know a priori what value NSPLIT will have, N words must be reserved for ISPLIT.)

M Output parameter.

M is INTEGER

The actual number of eigenvalues found. 0 <= M <= N. (See also the description of INFO=2,3.)

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On exit, the first M elements of W will contain the eigenvalue approximations. DLARRD computes an interval I_j = (a_j, b_j] that includes eigenvalue j. The eigenvalue approximation is given as the interval midpoint W(j)= (a_j + b_j)/2. The corresponding error is bounded by WERR(j) = abs(a_j - b_j)/2

WERR Output parameter.

WERR is DOUBLE PRECISION

WERR is an array, dimension (N). The error bound on the corresponding eigenvalue approximation in W.

WL Output parameter.

WL is DOUBLE PRECISION

WU Output parameter.

WU is DOUBLE PRECISION

The interval (WL, WU] contains all the wanted eigenvalues. If RANGE='V', then WL=VL and WU=VU. If RANGE='A', then WL and WU are the global Gerschgorin bounds on the spectrum. If RANGE='I', then WL and WU are computed by DLAEBZ from the index range specified.

IBLOCK Output parameter.

IBLOCK is INTEGER array, dimension (N)

At each row/column j where E(j) is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if INFO = 0, IBLOCK(i) specifies to which block (from 1 to the number of blocks) the eigenvalue W(i) belongs. (DLARRD may use the remaining N-M elements as workspace.)

INDEXW Output parameter.

INDEXW is INTEGER array, dimension (N)

The indices of the eigenvalues within each block (submatrix); for example, INDEXW(i)= j and IBLOCK(i)=k imply that the i-th eigenvalue W(i) is the j-th eigenvalue in block k.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (3*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: some or all of the eigenvalues failed to converge or were not computed: =1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. This is generally caused by unexpectedly inaccurate arithmetic. =2 or 3: RANGE='I' only: Not all of the eigenvalues IL:IU were found. Effect: M < IU+1-IL Cause: non-monotonic arithmetic, causing the Sturm sequence to be non-monotonic. Cure: recalculate, using RANGE='A', and pick out eigenvalues IL:IU. In some cases, increasing the PARAMETER "FUDGE" may make things work. = 4: RANGE='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed. Probable cause: your machine has sloppy floating-point arithmetic. Cure: Increase the PARAMETER "FUDGE", recompile, and try again.

Related Information

For this routine in other precisions, please see *slarrd*.

4.17.310 dlarre

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T, dlarre sets any "small" off-diagonal elements to zero, and for each unreduced block T_i, it finds (a) a suitable shift at one end of the block's spectrum, (b) the base representation, T_i - sigma_i I = L_i D_i L_i^T, and (c) eigenvalues of each L_i D_i L_i^T. The representations and eigenvalues found are then used by DSTEMR to compute the eigenvectors of T. The accuracy varies depending on whether bisection is used to find a few eigenvalues or the dqds algorithm (subroutine DLASQ2) to conpute all and then discard any unwanted one. As an added benefit, dlarre also outputs the n Gerschgorin intervals for the matrices L_i D_i L_i^T.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarre(RANGE, N, VL, VU, IL, IU, D, E, E2, RTOL1, RTOL2, SPLTOL,
                  NSPLIT, ISPLIT, M, W, WERR, WGAP, IBLOCK, INDEXW, GERS,
                  PIVMIN, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlarre_(const char *range, const armpl_int_t *n, double *vl, double *vu,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *il, const armpl_int_t *iu, double *d,
                double *e, double *e2, const double *rtol1, const double *rtol2,
                const double *spltol, armpl_int_t *nsplit, armpl_int_t *isplit,
                armpl_int_t *m, double *w, double *werr, double *wgap,
                armpl_int_t *iblock, armpl_int_t *indexw, double *gers,
                double *pivmin, double *work, armpl_int_t *iwork,
                armpl_int_t *info, ... );
```

Parameters

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found. = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N > 0.

VL Input and output parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound for the eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. If RANGE='I' or ='A', DLARRE computes bounds on the desired part of the spectrum.

VU Input and output parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound for the eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. If RANGE='I' or ='A', DLARRE computes bounds on the desired part of the spectrum.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, the N diagonal elements of the diagonal matrices D_i.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, the first (N-1) entries contain the subdiagonal elements of the tridiagonal matrix T; E(N) need not be set. On exit, E contains the subdiagonal elements of the unit bidiagonal matrices L_i. The entries E(ISPLIT(I)), 1 <= I <= NSPLIT, contain the base points sigma_i on output.

E2 Input and output parameter.

E2 is DOUBLE PRECISION

E2 is an array, dimension (N). On entry, the first (N-1) entries contain the SQUARES of the subdiagonal elements of the tridiagonal matrix T; E2(N) need not be set. On exit, the entries E2(ISPLIT(I)), 1 <= I <= NSPLIT, have been set to zero

RTOL1 Input parameter.

RTOL1 is DOUBLE PRECISION

RTOL2 Input parameter.

RTOL2 is DOUBLE PRECISION

Parameters for bisection. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|))

SPLTOL Input parameter.

SPLTOL is DOUBLE PRECISION

The threshold for splitting.

NSPLIT Output parameter.

NSPLIT is INTEGER

The number of blocks T splits into. 1 <= NSPLIT <= N.

ISPLIT Output parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.

M Output parameter.

M is INTEGER

The total number of eigenvalues (of all L_i D_i L_i^T) found.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the eigenvalues. The eigenvalues of each of the blocks, L_i D_i L_i^T, are sorted in ascending order (DLARRE may use the remaining N-M elements as workspace).

WERR Output parameter.

WERR is DOUBLE PRECISION

WERR is an array, dimension (N). The error bound on the corresponding eigenvalue in W.

WGAP Output parameter.

WGAP is DOUBLE PRECISION

WGAP is an array, dimension (N). The separation from the right neighbor eigenvalue in W. The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree. Exception: at the right end of a block we store the left gap

IBLOCK Output parameter.

IBLOCK is INTEGER array, dimension (N)

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first block from the top, =2 if W(i) belongs to the second block, etc.

INDEXW Output parameter.

INDEXW is INTEGER array, dimension (N)

The indices of the eigenvalues within each block (submatrix); for example, INDEXW(i)= 10 and IBLOCK(i)=2 imply that the i-th eigenvalue W(i) is the 10-th eigenvalue in block 2

GERS Output parameter.

GERS is DOUBLE PRECISION

GERS is an array, dimension (2*N). The N Gerschgorin intervals (the i-th Gerschgorin interval is (GERS(2*i-1), GERS(2*i)).

PIVMIN Output parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot in the Sturm sequence for T.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (6*N). Workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

Workspace.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: A problem occurred in DLARRE. < 0: One of the called subroutines signaled an internal problem. Needs inspection of the corresponding parameter IINFO for further information.

=-1: Problem in DLARRD. = 2: No base representation could be found in MAXTRY iterations. Increasing MAXTRY and recompilation might be a remedy. =-3: Problem in DLARRB when computing the refined root representation for DLASQ2. =-4: Problem in DLARRB when preforming bisection on the desired part of the spectrum. =-5: Problem in DLASQ2. =-6: Problem in DLASQ2.

Related Information

For this routine in other precisions, please see *slarre*.

4.17.311 dlarrf

Given the initial representation L D L^T and its cluster of close eigenvalues (in a relative measure), W(CLSTRT), W(CLSTRT+1), ... W(CLEND), dlarrf finds a new relatively robust representation L D L^T - SIGMA I = L(+) D(+) L(+)^T such that at least one of the eigenvalues of L(+) D(+) L(+)^T is relatively isolated.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarrf(N, D, L, LD, CLSTRT, CLEND, W, WGAP, WERR, SPDIAM, CLGAPL,
                  CLGAPR, PIVMIN, SIGMA, DPLUS, LPLUS, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlarrf_(const armpl_int_t *n, const double *d, const double *l,
             const double *ld, const armpl_int_t *clstrt,
             const armpl_int_t *clend, const double *w, double *wgap,
             const double *werr, const double *spdiam, const double *clgapl,
             double *clgapr, const double *pivmin, double *sigma,
             double *dplus, double *lplus, double *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix (subblock, if the matrix split).

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The N diagonal elements of the diagonal matrix D.

L Input parameter.

L is DOUBLE PRECISION

L is an array, dimension (N-1). The (N-1) subdiagonal elements of the unit bidiagonal matrix L.

LD Input parameter.

LD is DOUBLE PRECISION

LD is an array, dimension (N-1). The (N-1) elements L(i)*D(i).

CLSTRT Input parameter.

CLSTRT is INTEGER

The index of the first eigenvalue in the cluster.

CLEND Input parameter.

CLEND is INTEGER

The index of the last eigenvalue in the cluster.

W Input parameter.

W is DOUBLE PRECISION

W is an array, dimension. dimension is >= (CLEND-CLSTRT+1) The eigenvalue APPROXIMATIONS of L D L^T in ascending order. W(CLSTRT) through W(CLEND) form the cluster of relatively close eigenalues.

WGAP Input and output parameter.

WGAP is DOUBLE PRECISION

WGAP is an array, dimension. dimension is >= (CLEND-CLSTRT+1) The separation from the right neighbor eigenvalue in W.

WERR Input parameter.

WERR is DOUBLE PRECISION

WERR is an array, dimension. dimension is >= (CLEND-CLSTRT+1) WERR contain the semiwidth of the uncertainty interval of the corresponding eigenvalue APPROXIMATION in W

SPDIAM Input parameter.

SPDIAM is DOUBLE PRECISION

estimate of the spectral diameter obtained from the Gerschgorin intervals

CLGAPL Input parameter.

CLGAPL is DOUBLE PRECISION

CLGAPR Input parameter.

CLGAPR is DOUBLE PRECISION

absolute gap on each end of the cluster. Set by the calling routine to protect against shifts too close to eigenvalues outside the cluster.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot allowed in the Sturm sequence.

SIGMA Output parameter.

SIGMA is DOUBLE PRECISION

The shift used to form L(+) D(+) L(+)^T.

DPLUS Output parameter.

DPLUS is DOUBLE PRECISION

DPLUS is an array, dimension (N). The N diagonal elements of the diagonal matrix D(+).

LPLUS Output parameter.

LPLUS is DOUBLE PRECISION

LPLUS is an array, dimension (N-1). The first (N-1) elements of LPLUS contain the subdiagonal elements of the unit bidiagonal matrix L(+).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N). Workspace.

INFO Output parameter.

INFO is INTEGER

Signals processing OK (=0) or failure (=1)

Related Information

For this routine in other precisions, please see *slarrf*.

4.17.312 dlarrj

Given the initial eigenvalue approximations of T, dlarrj does bisection to refine the eigenvalues of T, W(IFIRST-OFFSET) through W(ILAST-OFFSET), to more accuracy. Initial guesses for these eigenvalues are input in W, the corresponding estimate of the error in these guesses in WERR. During bisection, intervals [left, right] are maintained by storing their mid-points and semi-widths in the arrays W and WERR respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarrj(N, D, E2, IFIRST, ILAST, RTOL, OFFSET, W, WERR, WORK, IWORK,
                  PIVMIN, SPDIAM, INFO)
```

C specification:

```
#include "armpl.h"

void dlarrj_(const armpl_int_t *n, const double *d, const double *e2,
             const armpl_int_t *ifirst, const armpl_int_t *ilast,
             const double *rtol, const armpl_int_t *offset, double *w,
             double *werr, double *work, armpl_int_t *iwork,
             const double *pivmin, const double *spdiam, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The N diagonal elements of T.

E2 Input parameter.

E2 is DOUBLE PRECISION

E2 is an array, dimension (N-1). The Squares of the (N-1) subdiagonal elements of T.

IFIRST Input parameter.

IFIRST is INTEGER

The index of the first eigenvalue to be computed.

ILAST Input parameter.

ILAST is INTEGER

The index of the last eigenvalue to be computed.

RTOL Input parameter.

RTOL is DOUBLE PRECISION

Tolerance for the convergence of the bisection intervals. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.RTOL*MAX(|LEFT|,|RIGHT|).

OFFSET Input parameter.

OFFSET is INTEGER

Offset for the arrays W and WERR, i.e., the IFIRST-OFFSET through ILAST-OFFSET elements of these arrays are to be used.

W Input and output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On input, W(IFIRST-OFFSET) through W(ILAST-OFFSET) are estimates of the eigenvalues of L D L^T indexed IFIRST through ILAST. On output, these estimates are refined.

WERR Input and output parameter.

WERR is DOUBLE PRECISION

WERR is an array, dimension (N). On input, WERR(IFIRST-OFFSET) through WERR(ILAST-OFFSET) are the errors in the estimates of the corresponding elements in W. On output, these errors are refined.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N). Workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (2*N)

Workspace.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot in the Sturm sequence for T.

SPDIAM Input parameter.

SPDIAM is DOUBLE PRECISION

The spectral diameter of T.

INFO Output parameter.

INFO is INTEGER

Error flag.

Related Information

For this routine in other precisions, please see *slarrj*.

4.17.313 dlarrk

dlarrk computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from DSTEMR.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan “Accurate Eigenvalues of a Symmetric Tridiagonal Matrix”, Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarrk(N, IW, GL, GU, D, E2, PIVMIN, RELTOL, W, WERR, INFO)
```

C specification:

```
#include "armpl.h"

void dlarrk_(const armpl_int_t *n, const armpl_int_t *iw, const double *gl,
             const double *gu, const double *d, const double *e2,
             const double *pivmin, const double *reltol, double *w,
             double *werr, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix T. N >= 0.

IW Input parameter.

IW is INTEGER

The index of the eigenvalues to be returned.

GL Input parameter.

GL is DOUBLE PRECISION

GU Input parameter.

GU is DOUBLE PRECISION

An upper and a lower bound on the eigenvalue.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E2 Input parameter.

E2 is DOUBLE PRECISION

E2 is an array, dimension (N-1). The (n-1) squared off-diagonal elements of the tridiagonal matrix T.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot allowed in the Sturm sequence for T.

RELTOL Input parameter.

RELTOL is DOUBLE PRECISION

The minimum relative width of an interval. When an interval is narrower than RELTOL times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.

W Output parameter.

W is DOUBLE PRECISION

WERR Output parameter.

WERR is DOUBLE PRECISION

The error bound on the corresponding eigenvalue approximation in W.

INFO Output parameter.

INFO is INTEGER

= 0: Eigenvalue converged = -1: Eigenvalue did NOT converge

Related Information

For this routine in other precisions, please see *slarrk*.

4.17.314 dlarrr

Perform tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarrr(N, D, E, INFO)
```

C specification:

```
#include "armpl.h"

void dlarrr_(const armpl_int_t *n, const double *d, double *e,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N > 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The N diagonal elements of the tridiagonal matrix T.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, the first (N-1) entries contain the subdiagonal elements of the tridiagonal matrix T; E(N) is set to ZERO.

INFO Output parameter.

INFO is INTEGER

INFO = 0(default) : the matrix warrants computations preserving relative accuracy. INFO = 1 : the matrix warrants computations guaranteeing only absolute accuracy.

Related Information

For this routine in other precisions, please see *slarrr*.

4.17.315 dlarrv

dlarrv computes the eigenvectors of the tridiagonal matrix T = L D L^T given L, D and APPROXIMATIONS to the eigenvalues of L D L^T . The input eigenvalues should have been computed by DLARRE.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarrv(N, VL, VU, D, L, PIVMIN, ISPLIT, M, DOL, DOU, MINRGP, RTOL1,
                  RTOL2, W, WERR, WGAP, IBLOCK, INDEXW, GERS, Z, LDZ, ISUPPZ,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlarrv_(const armpl_int_t *n, const double *vl, const double *vu,
             double *d, double *l, double *pivmin, const armpl_int_t *isplit,
             const armpl_int_t *m, const armpl_int_t *dol,
             const armpl_int_t *dou, const double *minrgp,
             const double *rtol1, const double *rtol2, double *w,
             double *werr, double *wgap, const armpl_int_t *iblock,
             const armpl_int_t *indexw, const double *gers, double *z,
             const armpl_int_t *ldz, armpl_int_t *isuppz, double *work,
             armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

VL Input parameter.

VL is DOUBLE PRECISION

Lower bound of the interval that contains the desired eigenvalues. VL < VU. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired RANGE.

VU Input parameter.

VU is DOUBLE PRECISION

Upper bound of the interval that contains the desired eigenvalues. VL < VU. Note: VU is currently not used by this implementation of DLARRV, VU is passed to DLARRV because it could be used compute gaps on the right end of the extremal eigenvalues. However, with not much initial accuracy in LAMBDA and VU, the formula can lead to an overestimation of the right gap and thus to inadequately early RQI 'convergence'. This is currently prevented this by forcing a small right gap. And so it turns out that VU is currently not used by this implementation of DLARRV.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the N diagonal elements of the diagonal matrix D. On exit, D may be overwritten.

L Input and output parameter.

L is DOUBLE PRECISION

L is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the unit bidiagonal matrix L are in elements 1 to N-1 of L (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by DLARRE. On exit, L is overwritten.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot allowed in the Sturm sequence.

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc.

M Input parameter.

M is INTEGER

The total number of input eigenvalues. 0 <= M <= N.

DOL Input parameter.

DOL is INTEGER

DOU Input parameter.

DOU is INTEGER

If the user wants to compute only selected eigenvectors from all the eigenvalues supplied, he can specify an index range DOL:DOU. Or else the setting DOL=1, DOU=M should be applied. Note that DOL and DOU refer to the order in which the eigenvalues are stored in W. If the user wants to compute only selected eigenpairs, then the columns DOL-1 to DOU+1 of the eigenvector space Z contain the computed eigenvectors. All other columns of Z are set to zero.

MINRGP Input parameter.

MINRGP is DOUBLE PRECISION

RTOL1 Input parameter.

RTOL1 is DOUBLE PRECISION

RTOL2 Input parameter.

RTOL2 is DOUBLE PRECISION

Parameters for bisection. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|))

W Input and output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements of W contain the APPROXIMATE eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block (The output array W from DLARRE is expected here). Furthermore, they are with respect to the shift of the corresponding root representation for their block. On exit, W holds the eigenvalues of the UNshifted matrix.

WERR Input and output parameter.

WERR is DOUBLE PRECISION

WERR is an array, dimension (N). The first M elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in W

WGAP Input and output parameter.

WGAP is DOUBLE PRECISION

WGAP is an array, dimension (N). The separation from the right neighbor eigenvalue in W.

IBLOCK Input parameter.

IBLOCK is INTEGER array, dimension (N)

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first block from the top, =2 if W(i) belongs to the second block, etc.

INDEXW Input parameter.

INDEXW is INTEGER array, dimension (N)

The indices of the eigenvalues within each block (submatrix); for example, INDEXW(i)= 10 and IBLOCK(i)=2 imply that the i-th eigenvalue W(i) is the 10-th eigenvalue in the second block.

GERS Input parameter.

GERS is DOUBLE PRECISION

GERS is an array, dimension (2*N). The N Gerschgorin intervals (the i-th Gerschgorin interval is (GERS(2*i-1), GERS(2*i)). The Gerschgorin intervals should be computed from the original UNshifted matrix.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the input eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least max(1, M) columns are supplied in the array Z.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The I-th eigenvector is nonzero only in elements ISUPPZ(2*I-1) through ISUPPZ(2*I).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (12*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (7*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

> 0: A problem occurred in DLARRV. < 0: One of the called subroutines signaled an internal problem. Needs inspection of the corresponding parameter IINFO for further information.

=-1: Problem in DLARRB when refining a child's eigenvalues. =-2: Problem in DLARRF when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter MINRGP smaller and recompile. However, as the orthogonality of the computed vectors is proportional to 1/MINRGP, the user should be aware that he might be trading in precision when he decreases MINRGP. =-3: Problem in DLARRB when refining a single eigenvalue after the Rayleigh correction was rejected. = 5: The Rayleigh Quotient Iteration failed to converge to full accuracy in MAXITR steps.

Related Information

For this routine in other precisions, please see *clarrv*, *slarrv* and *zlarrv*.

4.17.316 dlarscl2

DLARSCL2 performs a reciprocal diagonal scaling on an vector:

```
x <-- inv(D) * x
```

where the diagonal matrix D is stored as a vector.

Eventually to be replaced by BLAS_dge_diag_scale in the new BLAS standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarscl2(M, N, D, X, LDX)
```

C specification:

```
#include "armpl.h"

void dlarscl2_(const armpl_int_t *m, const armpl_int_t *n, const double *d,
               double *x, const armpl_int_t *ldx);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of D and X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of X. N >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (M). Diagonal matrix D, stored as a vector of length M.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, N). On entry, the vector X to be scaled by D. On exit, the scaled vector.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the vector X. LDX >= M.

Related Information

For this routine in other precisions, please see *clarscl2*, *slarscl2* and *zlarscl2*.

4.17.317 dlartg

`dlartg` generate a plane rotation so that

```
[  CS  SN  ]  .  [ F ]  =  [ R ]   where CS**2 + SN**2 = 1.
[ -SN  CS  ]     [ G ]     [ 0 ]
```

This is a slower, more accurate version of the BLAS1 routine DROTG, with the following other differences:

```
 F and G are unchanged on return.
If G=0, then CS=1 and SN=0.
If F=0 and (G .ne. 0), then CS=0 and SN=1 without doing any
   floating point operations (saves work in DBDSQR when
   there are zeros on the diagonal).
```

If F exceeds G in magnitude, CS will be positive.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlartg(F, G, CS, SN, R)
```

C specification:

```
#include "armpl.h"

void dlartg_(const double *f, const double *g, double *cs, double *sn,
             double *r);
```

Parameters

F Input parameter.

F is DOUBLE PRECISION

The first component of vector to be rotated.

G Input parameter.

G is DOUBLE PRECISION

The second component of vector to be rotated.

CS Output parameter.

CS is DOUBLE PRECISION

The cosine of the rotation.

SN Output parameter.

SN is DOUBLE PRECISION

The sine of the rotation.

R Output parameter.

R is DOUBLE PRECISION

The nonzero component of the rotated vector.

This version has a few statements commented out for thread safety (machine parameters are computed on each entry). 10 feb 03, SJH.

Related Information

For this routine in other precisions, please see *clartg*, *slartg* and *zlartg*.

4.17.318 dlartgp

`dlartgp` generates a plane rotation so that

```
[  CS  SN  ]  .  [ F ]  =  [ R ]   where CS**2 + SN**2 = 1.
[ -SN  CS  ]     [ G ]     [ 0 ]
```

This is a slower, more accurate version of the Level 1 BLAS routine DROTG, with the following other differences:

```
F and G are unchanged on return.
If G=0, then CS=(+/-)1 and SN=0.
If F=0 and (G .ne. 0), then CS=0 and SN=(+/-)1.
```

The sign is chosen so that R >= 0.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlartgp(F, G, CS, SN, R)
```

C specification:

```
#include "armpl.h"

void dlartgp_(const double *f, const double *g, double *cs, double *sn,
              double *r);
```

Parameters

F Input parameter.

F is DOUBLE PRECISION

The first component of vector to be rotated.

G Input parameter.

G is DOUBLE PRECISION

The second component of vector to be rotated.

CS Output parameter.

CS is DOUBLE PRECISION

The cosine of the rotation.

SN Output parameter.

SN is DOUBLE PRECISION

The sine of the rotation.

R Output parameter.

R is DOUBLE PRECISION

The nonzero component of the rotated vector.

This version has a few statements commented out for thread safety (machine parameters are computed on each entry). 10 feb 03, SJH.

Related Information

For this routine in other precisions, please see *slartgp*. It also exists with a native C interface as *LAPACKE_dlartgp*.

4.17.319 dlartgs

dlartgs generates a plane rotation designed to introduce a bulge in Golub-Reinsch-style implicit QR iteration for the bidiagonal SVD problem. X and Y are the top-row entries, and SIGMA is the shift. The computed CS and SN define a plane rotation satisfying

```
[  CS  SN  ]  .  [ X^2 - SIGMA ]  =  [ R ],
[ -SN  CS  ]     [    X * Y    ]     [ 0 ]
```

with R nonnegative. If X^2 - SIGMA and X * Y are 0, then the rotation is by PI/2.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlartgs(X, Y, SIGMA, CS, SN)
```

C specification:

```
#include "armpl.h"

void dlartgs_(const double *x, const double *y, const double *sigma,
              double *cs, double *sn);
```

Parameters

X Input parameter.

X is DOUBLE PRECISION

The (1,1) entry of an upper bidiagonal matrix.

Y Input parameter.

Y is DOUBLE PRECISION

The (1,2) entry of an upper bidiagonal matrix.

SIGMA Input parameter.

SIGMA is DOUBLE PRECISION

The shift.

CS Output parameter.

CS is DOUBLE PRECISION

The cosine of the rotation.

SN Output parameter.

SN is DOUBLE PRECISION

The sine of the rotation.

Related Information

For this routine in other precisions, please see *slartgs*. It also exists with a native C interface as *LAPACKE_dlartgs*.

4.17.320 dlartv

dlartv applies a vector of real plane rotations to elements of the real vectors x and y. For i = 1,2,...,n

```
( x(i) ) := (  c(i)  s(i) ) ( x(i) )
( y(i) )    ( -s(i)  c(i) ) ( y(i) )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlartv(N, X, INCX, Y, INCY, C, S, INCC)
```

C specification:

```
#include "armpl.h"

void dlartv_(const armpl_int_t *n, double *x, const armpl_int_t *incx,
             double *y, const armpl_int_t *incy, const double *c,
             const double *s, const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be applied.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array,. dimension (1+(N-1)*INCX) The vector x.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array,. dimension (1+(N-1)*INCY) The vector y.

INCY Input parameter.

INCY is INTEGER

The increment between elements of Y. INCY > 0.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (1+(N-1)*INCC). The sines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C and S. INCC > 0.

Related Information

For this routine in other precisions, please see *clartv*, *slartv* and *zlartv*.

4.17.321 dlaruv

dlaruv returns a vector of n random real numbers from a uniform (0,1) distribution (n <= 128).

This is an auxiliary routine called by DLARNV and ZLARNV.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaruv(ISEED, N, X)
```

C specification:

```
#include "armpl.h"

void dlaruv_(armpl_int_t *iseed, const armpl_int_t *n, double *x);
```

Parameters

ISEED Input and output parameter.

ISEED is INTEGER array, dimension (4)

On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and ISEED(4) must be odd. On exit, the seed is updated.

N Input parameter.

N is INTEGER

The number of random numbers to be generated. N <= 128.

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). The generated random numbers.

Related Information

For this routine in other precisions, please see *slaruv*.

4.17.322 dlarz

dlarz applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**T
```

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix.

H is a product of k elementary reflectors as returned by DTZRZF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarz(SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void dlarz_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *l, const double *v, const armpl_int_t *incv,
            const double *tau, double *c, const armpl_int_t *ldc,
            double *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

L Input parameter.

L is INTEGER

The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension (1+(L-1)*abs(INCV)). The vector v in the representation of H as returned by DTZRZF. V is not used if TAU = 0.

INCV Input parameter.

INCV is INTEGER

The increment between elements of v. INCV <> 0.

TAU Input parameter.

TAU is DOUBLE PRECISION

The value tau in the representation of H.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R'

Related Information

For this routine in other precisions, please see *clarz*, *slarz* and *zlarz*.

4.17.323 dlarzb

dlarzb applies a real block reflector H or its transpose H^T to a real distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarzb(SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV, T, LDT, C,
                  LDC, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void dlarzb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l, const double *v,
             const armpl_int_t *ldv, const double *t, const armpl_int_t *ldt,
             double *c, const armpl_int_t *ldc, double *work,
             const armpl_int_t *ldwork, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^T from the Left = 'R': apply H or H^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'C': apply H^T (Transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columnwise (not supported yet) = 'R': Rowwise

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

K Input parameter.

K is INTEGER

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L Input parameter.

L is INTEGER

The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV,NV).. If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= L; if STOREV = 'R', LDV >= K.

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by H* C or H^T * C or C*H or C*H^T .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LDWORK, K) .

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1, N); if SIDE = 'R', LDWORK >= max(1, M).

Related Information

For this routine in other precisions, please see *clarzb*, *slarzb* and *zlarzb*.

4.17.324 dlarzt

dlarzt forms the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

```
H  =  I - V * T * V**T
```

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

```
H  =  I - V**T * T * V
```

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlarzt(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

C specification:

```
#include "armpl.h"

void dlarzt_(const char *direct, const char *storev, const armpl_int_t *n,
             const armpl_int_t *k, double *v, const armpl_int_t *ldv,
             const double *tau, double *t, const armpl_int_t *ldt, ... );
```

Parameters

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details): = 'C': columnwise (not supported yet) = 'R': rowwise

N Input parameter.

N is INTEGER

The order of the block reflector H. N >= 0.

K Input parameter.

K is INTEGER

The order of the triangular factor T (= the number of elementary reflectors). K >= 1.

V Input and output parameter.

V is DOUBLE PRECISION

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, N) if STOREV = 'R' The matrix V. See further details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, K). The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

Related Information

For this routine in other precisions, please see *clarzt*, *slarzt* and *zlarzt*.

4.17.325 dlas2

dlas2 computes the singular values of the 2-by-2 matrix

```
[  F   G  ]
[  0   H  ].
```

On return, SSMIN is the smaller singular value and SSMAX is the larger singular value.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlas2(F, G, H, SSMIN, SSMAX)
```

C specification:

```
#include "armpl.h"

void dlas2_(const double *f, const double *g, const double *h, double *ssmin,
            double *ssmax);
```

Parameters

F Input parameter.

F is DOUBLE PRECISION

The (1,1) element of the 2-by-2 matrix.

G Input parameter.

G is DOUBLE PRECISION

The (1,2) element of the 2-by-2 matrix.

H Input parameter.

H is DOUBLE PRECISION

The (2,2) element of the 2-by-2 matrix.

SSMIN Output parameter.

SSMIN is DOUBLE PRECISION

The smaller singular value.

SSMAX Output parameter.

SSMAX is DOUBLE PRECISION

The larger singular value.

Related Information

For this routine in other precisions, please see *slas2*.

4.17.326 dlascl

dlascl multiplies the M by N real matrix A by the real scalar CTO/CFROM. This is done without over/underflow as long as the final result CTO*A(I,J)/CFROM does not over/underflow. TYPE specifies that A may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlascl(TYPE, KL, KU, CFROM, CTO, M, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dlascl_(const char *type, const armpl_int_t *kl, const armpl_int_t *ku,
             const double *cfrom, const double *cto, const armpl_int_t *m,
             const armpl_int_t *n, double *a, const armpl_int_t *lda,
             armpl_int_t *info, ... );
```

Parameters

TYPE Input parameter.

TYPE is CHARACTER*1

TYPE indices the storage type of the input matrix. = 'G': A is a full matrix. = 'L': A is a lower triangular matrix. = 'U': A is an upper triangular matrix. = 'H': A is an upper Hessenberg matrix. = 'B': A is a symmetric band matrix with lower bandwidth KL and upper bandwidth KU and with the only the lower half stored. = 'Q': A is a symmetric band matrix with lower bandwidth KL and upper bandwidth KU and with the only the upper half stored. = 'Z': A is a band matrix with lower bandwidth KL and upper bandwidth KU. See DGBTRF for storage details.

KL Input parameter.

KL is INTEGER

The lower bandwidth of A. Referenced only if TYPE = 'B', 'Q' or 'Z'.

KU Input parameter.

KU is INTEGER

The upper bandwidth of A. Referenced only if TYPE = 'B', 'Q' or 'Z'.

CFROM Input parameter.

CFROM is DOUBLE PRECISION

CTO Input parameter.

CTO is DOUBLE PRECISION

The matrix A is multiplied by CTO/CFROM. A(I,J) is computed without over/underflow if the final result CTO*A(I,J)/CFROM can be represented without over/underflow. CFROM must be nonzero.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The matrix to be multiplied by CTO/CFROM. See TYPE for the storage type.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If TYPE = 'G', 'L', 'U', 'H', LDA >= max(1, M); TYPE = 'B', LDA >= KL+1; TYPE = 'Q', LDA >= KU+1; TYPE = 'Z', LDA >= 2*KL+KU+1.

INFO Output parameter.

INFO is INTEGER

0 - successful exit <0 - if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *clascl*, *slascl* and *zlascl*. It also exists with a native C interface as *LAPACKE_dlascl*.

4.17.327 dlascl2

dlascl2 performs a diagonal scaling on a vector:

```
x <-- D * x
```

where the diagonal matrix D is stored as a vector.

Eventually to be replaced by BLAS_dge_diag_scale in the new BLAS standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlascl2(M, N, D, X, LDX)
```

C specification:

```
#include "armpl.h"

void dlascl2_(const armpl_int_t *m, const armpl_int_t *n, const double *d,
              double *x, const armpl_int_t *ldx);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of D and X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of X. N >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, length M. Diagonal matrix D, stored as a vector of length M.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, N). On entry, the vector X to be scaled by D. On exit, the scaled vector.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the vector X. LDX >= M.

Related Information

For this routine in other precisions, please see *clascl2*, *slascl2* and *zlascl2*.

4.17.328 dlasd0

Using a divide and conquer approach, dlasd0 computes the singular value decomposition (SVD) of a real upper bidiagonal N-by-M matrix B with diagonal D and offdiagonal E, where M = N + SQRE. The algorithm computes orthogonal matrices U and VT such that B = U * S * VT. The singular values S are overwritten on D.

A related subroutine, DLASDA, computes only the singular values, and optionally, the singular vectors in compact form.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasd0(N, SQRE, D, E, U, LDU, VT, LDVT, SMLSIZ, IWORK, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlasd0_(const armpl_int_t *n, const armpl_int_t *sqre, double *d,
             double *e, double *u, const armpl_int_t *ldu, double *vt,
             const armpl_int_t *ldvt, const armpl_int_t *smlsiz,
             armpl_int_t *iwork, double *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

On entry, the row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array D.

SQRE Input parameter.

SQRE is INTEGER

Specifies the column dimension of the bidiagonal matrix. = 0: The bidiagonal matrix has column dimension M = N; = 1: The bidiagonal matrix has column dimension M = N+1;

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry D contains the main diagonal of the bidiagonal matrix. On exit D, if INFO = 0, contains its singular values.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (M-1). Contains the subdiagonal entries of the bidiagonal matrix. On exit, E has been destroyed.

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, N). On exit, U contains the left singular vectors.

LDU Input parameter.

LDU is INTEGER

On entry, leading dimension of U.

VT Output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDVT, M). On exit, VT^T contains the right singular vectors.

LDVT Input parameter.

LDVT is INTEGER

On entry, leading dimension of VT.

SMLSIZ Input parameter.

SMLSIZ is INTEGER

On entry, maximum size of the subproblems at the bottom of the computation tree.

IWORK Output parameter.

IWORK is INTEGER array, dimension (8*N)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*M2+2*M)** .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *slasd0*.

4.17.329 dlasd1

dlasd1 computes the SVD of an upper bidiagonal N-by-M matrix B, where N = NL + NR + 1 and M = N + SQRE. dlasd1 is called from DLASD0.

A related subroutine DLASD7 handles the case in which the singular values (and the singular vectors in factored form) are desired.

dlasd1 computes the SVD as follows:

```
             ( D1(in)     0     0        0 )
B = U(in) * (   Z1**T     a    Z2**T     b ) * VT(in)
             (   0        0    D2(in)    0 )

  = U(out) * ( D(out) 0) * VT(out)
```

where Z^T = ($Z1^T$ a $Z2^T$ b) = u^T VT^T , and u is a vector of dimension M with ALPHA and BETA in the NL+1 and NL+2 th entries and zeros elsewhere; and the entry b is empty if SQRE = 0.

The left singular vectors of the original matrix are stored in U, and the transpose of the right singular vectors are stored in VT, and the singular values are in D. The algorithm consists of three stages:

```
 The first stage consists of deflating the size of the problem
when there are multiple singular values or when there are zeros in
the Z vector.  For each such occurrence the dimension of the
secular equation problem is reduced by one.  This stage is
performed by the routine DLASD2.

The second stage consists of calculating the updated
singular values. This is done by finding the square roots of the
roots of the secular equation via the routine DLASD4 (as called
by DLASD3). This routine also calculates the singular vectors of
the current problem.

The final stage consists of computing the updated singular vectors
directly using the updated singular values.  The singular vectors
for the current problem are multiplied with the singular vectors
from the overall problem.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasd1(NL, NR, SQRE, D, ALPHA, BETA, U, LDU, VT, LDVT, IDXQ, IWORK,
                  WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlasd1_(const armpl_int_t *nl, const armpl_int_t *nr,
             const armpl_int_t *sqre, double *d, double *alpha, double *beta,
             double *u, const armpl_int_t *ldu, double *vt,
             const armpl_int_t *ldvt, armpl_int_t *idxq, armpl_int_t *iwork,
             double *work, armpl_int_t *info);
```

Parameters

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has row dimension N = NL + NR + 1, and column dimension M = N + SQRE.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array,. dimension (N = NL+NR+1). On entry D(1:NL,1:NL) contains the singular values of the upper block; and D(NL+2:N) contains the singular values of the lower block. On exit D(1:N) contains the singular values of the modified matrix.

ALPHA Input and output parameter.

ALPHA is DOUBLE PRECISION

Contains the diagonal element associated with the added row.

BETA Input and output parameter.

BETA is DOUBLE PRECISION

Contains the off-diagonal element associated with the added row.

U Input and output parameter.

U is DOUBLE PRECISION

U is an array, dimension(LDU,N). On entry U(1:NL, 1:NL) contains the left singular vectors of the upper block; U(NL+2:N, NL+2:N) contains the left singular vectors of the lower block. On exit U contains the left singular vectors of the bidiagonal matrix.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, N).

VT Input and output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension(LDVT,M). where M = N + SQRE. On entry VT(1:NL+1, 1:NL+1)^T contains the right singular vectors of the upper block; VT(NL+2:M, NL+2:M)^T contains the right singular vectors of the lower block. On exit VT^T contains the right singular vectors of the bidiagonal matrix.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= max(1, M).

IDXQ Input and output parameter.

IDXQ is INTEGER array, dimension(N)

This contains the permutation which will reintegrate the subproblem just solved back into sorted order, i.e. D(IDXQ(I = 1, N)) will be in ascending order.

IWORK Output parameter.

IWORK is INTEGER array, dimension(4 * N)

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension(3*M2 + 2*M)** .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *slasd1*.

4.17.330 dlasd2

dlasd2 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

dlasd2 is called from DLASD1.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasd2(NL, NR, SQRE, K, D, Z, ALPHA, BETA, U, LDU, VT, LDVT,
                  DSIGMA, U2, LDU2, VT2, LDVT2, IDXP, IDX, IDXC, IDXQ, COLTYP,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dlasd2_(const armpl_int_t *nl, const armpl_int_t *nr,
             const armpl_int_t *sqre, armpl_int_t *k, double *d, double *z,
             const double *alpha, const double *beta, double *u,
             const armpl_int_t *ldu, double *vt, const armpl_int_t *ldvt,
             double *dsigma, double *u2, const armpl_int_t *ldu2, double *vt2,
             const armpl_int_t *ldvt2, armpl_int_t *idxp, armpl_int_t *idx,
             armpl_int_t *idxc, armpl_int_t *idxq, armpl_int_t *coltyp,
             armpl_int_t *info);
```

Parameters

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has N = NL + NR + 1 rows and M = N + SQRE >= N columns.

K Output parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. 1 <= K <=N.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension(N). On entry D contains the singular values of the two submatrices to be combined. On exit D contains the trailing (N-K) updated singular values (those which were deflated) sorted into increasing order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension(N). On exit Z contains the updating row vector in the secular equation.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

Contains the diagonal element associated with the added row.

BETA Input parameter.

BETA is DOUBLE PRECISION

Contains the off-diagonal element associated with the added row.

U Input and output parameter.

U is DOUBLE PRECISION

U is an array, dimension(LDU,N). On entry U contains the left singular vectors of two submatrices in the two square blocks with corners at (1,1), (NL, NL), and (NL+2, NL+2), (N,N). On exit U contains the trailing (N-K) updated left singular vectors (those which were deflated) in its last N-K columns.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= N.

VT Input and output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension(LDVT,M). On entry VT^T contains the right singular vectors of two submatrices in the two square blocks with corners at (1,1), (NL+1, NL+1), and (NL+2, NL+2), (M,M). On exit VT^T contains the trailing (N-K) updated right singular vectors (those which were deflated) in its last N-K columns. In case SQRE =1, the last row of VT spans the right null space.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= M.

DSIGMA Output parameter.

DSIGMA is DOUBLE PRECISION

DSIGMA is an array, dimension (N). Contains a copy of the diagonal elements (K-1 singular values and one zero) in the secular equation.

U2 Output parameter.

U2 is DOUBLE PRECISION

U2 is an array, dimension(LDU2,N). Contains a copy of the first K-1 left singular vectors which will be used by DLASD3 in a matrix multiply (DGEMM) to solve for the new left singular vectors. U2 is arranged into four blocks. The first block contains a column with 1 at NL+1 and zero everywhere else; the second block contains non-zero entries only at and above NL; the third contains non-zero entries only below NL+1; and the fourth is dense.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of the array U2. LDU2 >= N.

VT2 Output parameter.

VT2 is DOUBLE PRECISION

VT2 is an array, dimension(LDVT2,N). $VT2^T$ contains a copy of the first K right singular vectors which will be used by DLASD3 in a matrix multiply (DGEMM) to solve for the new right singular vectors. VT2 is arranged into three blocks. The first block contains a row that corresponds to the special 0 diagonal element in SIGMA; the second block contains non-zeros only at and before NL +1; the third block contains non-zeros only at and after NL +2.

LDVT2 Input parameter.

LDVT2 is INTEGER

The leading dimension of the array VT2. LDVT2 >= M.

IDXP Output parameter.

IDXP is INTEGER array, dimension(N)

This will contain the permutation used to place deflated values of D at the end of the array. On output IDXP(2:K) points to the nondeflated D-values and IDXP(K+1:N) points to the deflated singular values.

IDX Output parameter.

IDX is INTEGER array, dimension(N)

This will contain the permutation used to sort the contents of D into ascending order.

IDXC Output parameter.

IDXC is INTEGER array, dimension(N)

This will contain the permutation used to arrange the columns of the deflated U matrix into three groups: the first group contains non-zero entries only at and above NL, the second contains non-zero entries only below NL+2, and the third is dense.

IDXQ Input and output parameter.

IDXQ is INTEGER array, dimension(N)

This contains the permutation which separately sorts the two sub-problems in D into ascending order. Note that entries in the first hlaf of this permutation must first be moved one position backward; and entries in the second half must first have NL+1 added to their values.

COLTYP Output parameter.

COLTYP is INTEGER array, dimension(N)

As workspace, this will contain a label which will indicate which of the following types a column in the U2 matrix or a row in the VT2 matrix is: 1 : non-zero in the upper half only 2 : non-zero in the lower half only 3 : dense 4 : deflated

On exit, it is an array of dimension 4, with COLTYP(I) being the dimension of the I-th type columns.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *slasd2*.

4.17.331 dlasd3

dlasd3 finds all the square roots of the roots of the secular equation, as defined by the values in D and Z. It makes the appropriate calls to DLASD4 and then updates the singular vectors by matrix multiplication.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

dlasd3 is called from DLASD1.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasd3(NL, NR, SQRE, K, D, Q, LDQ, DSIGMA, U, LDU, U2, LDU2, VT,
                  LDVT, VT2, LDVT2, IDXC, CTOT, Z, INFO)
```

C specification:

```
#include "armpl.h"

void dlasd3_(const armpl_int_t *nl, const armpl_int_t *nr,
             const armpl_int_t *sqre, const armpl_int_t *k, double *d,
             double *q, const armpl_int_t *ldq, const double *dsigma,
             double *u, const armpl_int_t *ldu, double *u2,
             const armpl_int_t *ldu2, double *vt, const armpl_int_t *ldvt,
             double *vt2, const armpl_int_t *ldvt2, const armpl_int_t *idxc,
             const armpl_int_t *ctot, const double *z, armpl_int_t *info);
```

Parameters

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has N = NL + NR + 1 rows and M = N + SQRE >= N columns.

K Input parameter.

K is INTEGER

The size of the secular equation, 1 =< K = < N.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension(K). On exit the square roots of the roots of the secular equation, in ascending order.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, K) .

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= K.

DSIGMA Input and output parameter.

DSIGMA is DOUBLE PRECISION

DSIGMA is an array, dimension(K). The first K elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

U Output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, N). The last N - K columns of this matrix contain the deflated left singular vectors.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= N.

U2 Input parameter.

U2 is DOUBLE PRECISION

U2 is an array, dimension (LDU2, N). The first K columns of this matrix contain the non-deflated left singular vectors for the split problem.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of the array U2. LDU2 >= N.

VT Output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDVT, M). The last M - K columns of VT^T contain the deflated right singular vectors.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= N.

VT2 Input and output parameter.

VT2 is DOUBLE PRECISION

VT2 is an array, dimension (LDVT2, N). The first K columns of $VT2^T$ contain the non-deflated right singular vectors for the split problem.

LDVT2 Input parameter.

LDVT2 is INTEGER

The leading dimension of the array VT2. LDVT2 >= N.

IDXC Input parameter.

IDXC is INTEGER array, dimension (N)

The permutation used to arrange the columns of U (and rows of VT) into three groups: the first group contains non-zero entries only at and above (or before) NL +1; the second contains non-zero entries only at and below (or after) NL+2; and the third is dense. The first column of U and the row of VT are treated separately, however.

The rows of the singular vectors found by DLASD4 must be likewise permuted before the matrix multiplies can take place.

CTOT Input parameter.

CTOT is INTEGER array, dimension (4)

A count of the total number of the various types of columns in U (or rows in VT), as described in IDXC. The fourth column type is any column which has been deflated.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (K). The first K elements of this array contain the components of the deflation-adjusted updating row vector.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *slasd3*.

4.17.332 dlasd4

This subroutine computes the square root of the I-th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix whose entries are given as the squares of the corresponding entries in the array d, and that

```
0 <= D(i) < D(j)  for  i < j
```

and that RHO > 0. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

```
diag( D ) * diag( D ) +  RHO * Z * Z_transpose.
```

where we assume the Euclidean norm of Z is 1.

The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasd4(N, I, D, Z, DELTA, RHO, SIGMA, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlasd4_(const armpl_int_t *n, const armpl_int_t *i, const double *d,
             const double *z, double *delta, const double *rho, double *sigma,
             double *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The length of all arrays.

I Input parameter.

I is INTEGER

The index of the eigenvalue to be computed. 1 <= I <= N.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The original eigenvalues. It is assumed that they are in order, 0 <= D(I) < D(J) for I < J.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (N). The components of the updating vector.

DELTA Output parameter.

DELTA is DOUBLE PRECISION

DELTA is an array, dimension (N). If N .ne. 1, DELTA contains (D(j) - sigma_I) in its j-th component. If N = 1, then DELTA(1) = 1. The vector DELTA contains the information necessary to construct the (singular) eigenvectors.

RHO Input parameter.

RHO is DOUBLE PRECISION

The scalar in the symmetric updating formula.

SIGMA Output parameter.

SIGMA is DOUBLE PRECISION

The computed sigma_I, the I-th updated eigenvalue.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N). If N .ne. 1, WORK contains (D(j) + sigma_I) in its j-th component. If N = 1, then WORK(1) = 1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = 1, the updating process failed.

Related Information

For this routine in other precisions, please see *slasd4*.

4.17.333 dlasd5

This subroutine computes the square root of the I-th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix

```
diag( D ) * diag( D ) +  RHO * Z * transpose(Z) .
```

The diagonal entries in the array D are assumed to satisfy

```
0 <= D(i) < D(j)  for  i < j .
```

We also assume RHO > 0 and that the Euclidean norm of the vector Z is one.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasd5(I, D, Z, DELTA, RHO, DSIGMA, WORK)
```

C specification:

```
#include "armpl.h"

void dlasd5_(const armpl_int_t *i, const double *d, const double *z,
             double *delta, const double *rho, double *dsigma, double *work);
```

Parameters

I Input parameter.

I is INTEGER

The index of the eigenvalue to be computed. I = 1 or I = 2.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (2). The original eigenvalues. We assume 0 <= D(1) < D(2).

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (2). The components of the updating vector.

DELTA Output parameter.

DELTA is DOUBLE PRECISION

DELTA is an array, dimension (2). Contains (D(j) - sigma_I) in its j-th component. The vector DELTA contains the information necessary to construct the eigenvectors.

RHO Input parameter.

RHO is DOUBLE PRECISION

The scalar in the symmetric updating formula.

DSIGMA Output parameter.

DSIGMA is DOUBLE PRECISION

The computed sigma_I, the I-th updated eigenvalue.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2). WORK contains (D(j) + sigma_I) in its j-th component.

Related Information

For this routine in other precisions, please see *slasd5*.

4.17.334 dlasd6

dlasd6 computes the SVD of an updated upper bidiagonal matrix B obtained by merging two smaller ones by appending a row. This routine is used only for the problem which requires all singular values and optionally singular vector matrices in factored form. B is an N-by-M matrix with N = NL + NR + 1 and M = N + SQRE. A related subroutine, DLASD1, handles the case in which all singular values and singular vectors of the bidiagonal matrix are desired.

dlasd6 computes the SVD as follows:

```
              ( D1(in)     0     0        0 )
B = U(in) * (    Z1**T     a    Z2**T     b ) * VT(in)
              (    0        0    D2(in)    0 )

  = U(out) * ( D(out) 0) * VT(out)
```

where Z^T = ($Z1^T$ a $Z2^T$ b) = u^T VT^T , and u is a vector of dimension M with ALPHA and BETA in the NL+1 and NL+2 th entries and zeros elsewhere; and the entry b is empty if SQRE = 0.

The singular values of B can be computed using D1, D2, the first components of all the right singular vectors of the lower block, and the last components of all the right singular vectors of the upper block. These components are stored and updated in VF and VL, respectively, in dlasd6. Hence U and VT are not explicitly referenced.

The singular values are stored in D. The algorithm consists of two stages:

```
 The first stage consists of deflating the size of the problem
when there are multiple singular values or if there is a zero
in the Z vector. For each such occurrence the dimension of the
secular equation problem is reduced by one. This stage is
performed by the routine DLASD7.

The second stage consists of calculating the updated
singular values. This is done by finding the roots of the
secular equation via the routine DLASD4 (as called by DLASD8).
This routine also updates VF and VL and computes the distances
between the updated singular values and the old singular
values.
```

dlasd6 is called from DLASDA.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasd6(ICOMPQ, NL, NR, SQRE, D, VF, VL, ALPHA, BETA, IDXQ, PERM,
                  GIVPTR, GIVCOL, LDGCOL, GIVNUM, LDGNUM, POLES, DIFL, DIFR,
                  Z, K, C, S, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlasd6_(const armpl_int_t *icompq, const armpl_int_t *nl,
             const armpl_int_t *nr, const armpl_int_t *sqre, double *d,
             double *vf, double *vl, double *alpha, double *beta,
             armpl_int_t *idxq, armpl_int_t *perm, armpl_int_t *givptr,
             armpl_int_t *givcol, const armpl_int_t *ldgcol, double *givnum,
             const armpl_int_t *ldgnum, double *poles, double *difl,
             double *difr, double *z, armpl_int_t *k, double *c, double *s,
             double *work, armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in factored form: = 0: Compute singular values only. = 1: Compute singular vectors in factored form as well.

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has row dimension N = NL + NR + 1, and column dimension M = N + SQRE.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (NL+NR+1).. On entry D(1:NL,1:NL) contains the singular values of the upper block, and D(NL+2:N) contains the singular values of the lower block. On exit D(1:N) contains the singular values of the modified matrix.

VF Input and output parameter.

VF is DOUBLE PRECISION

VF is an array, dimension (M). On entry, VF(1:NL+1) contains the first components of all right singular vectors of the upper block; and VF(NL+2:M) contains the first components of all right singular vectors of the lower block. On exit, VF contains the first components of all right singular vectors of the bidiagonal matrix.

VL Input and output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (M). On entry, VL(1:NL+1) contains the last components of all right singular vectors of the upper block; and VL(NL+2:M) contains the last components of all right singular vectors of the lower block. On exit, VL contains the last components of all right singular vectors of the bidiagonal matrix.

ALPHA Input and output parameter.

ALPHA is DOUBLE PRECISION

Contains the diagonal element associated with the added row.

BETA Input and output parameter.

BETA is DOUBLE PRECISION

Contains the off-diagonal element associated with the added row.

IDXQ Input and output parameter.

IDXQ is INTEGER array, dimension (N)

This contains the permutation which will reintegrate the subproblem just solved back into sorted order, i.e. D(IDXQ(I = 1, N)) will be in ascending order.

PERM Output parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) to be applied to each block. Not referenced if ICOMPQ = 0.

GIVPTR Output parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem. Not referenced if ICOMPQ = 0.

GIVCOL Output parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL Input parameter.

LDGCOL is INTEGER

leading dimension of GIVCOL, must be at least N.

GIVNUM Output parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (LDGNUM, 2). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM Input parameter.

LDGNUM is INTEGER

The leading dimension of GIVNUM and POLES, must be at least N.

POLES Output parameter.

POLES is DOUBLE PRECISION

POLES is an array, dimension (LDGNUM, 2). On exit, POLES(1,*) is an array containing the new singular values obtained from solving the secular equation, and POLES(2,*) is an array containing the poles in the secular equation. Not referenced if ICOMPQ = 0.

DIFL Output parameter.

DIFL is DOUBLE PRECISION

DIFL is an array, dimension (N). On exit, DIFL(I) is the distance between I-th updated (undeflated) singular value and the I-th (undeflated) old singular value.

DIFR Output parameter.

DIFR is DOUBLE PRECISION

DIFR is an array,. dimension (LDDIFR, 2) if ICOMPQ = 1 and dimension (K) if ICOMPQ = 0. On exit, DIFR(I,1) = D(I) - DSIGMA(I+1), DIFR(K,1) is not defined and will not be referenced.

If ICOMPQ = 1, DIFR(1:K,2) is an array containing the normalizing factors for the right singular vector matrix.

See DLASD8 for details on DIFL and DIFR.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (M). The first elements of this array contain the components of the deflation-adjusted updating row vector.

K Output parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. 1 <= K <=N.

C Output parameter.

C is DOUBLE PRECISION

C contains garbage if SQRE =0 and the C-value of a Givens rotation related to the right null space if SQRE = 1.

S Output parameter.

S is DOUBLE PRECISION

S contains garbage if SQRE =0 and the S-value of a Givens rotation related to the right null space if SQRE = 1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4 * M) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (3 * N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *slasd6*.

4.17.335 dlasd7

dlasd7 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

dlasd7 is called from DLASD6.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasd7(ICOMPQ, NL, NR, SQRE, K, D, Z, ZW, VF, VFW, VL, VLW, ALPHA,
                  BETA, DSIGMA, IDX, IDXP, IDXQ, PERM, GIVPTR, GIVCOL, LDGCOL,
                  GIVNUM, LDGNUM, C, S, INFO)
```

C specification:

```
#include "armpl.h"

void dlasd7_(const armpl_int_t *icompq, const armpl_int_t *nl,
             const armpl_int_t *nr, const armpl_int_t *sqre, armpl_int_t *k,
             double *d, double *z, double *zw, double *vf, double *vfw,
             double *vl, double *vlw, const double *alpha, const double *beta,
             double *dsigma, armpl_int_t *idx, armpl_int_t *idxp,
             const armpl_int_t *idxq, armpl_int_t *perm, armpl_int_t *givptr,
             armpl_int_t *givcol, const armpl_int_t *ldgcol, double *givnum,
             const armpl_int_t *ldgnum, double *c, double *s,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in compact form, as follows: = 0: Compute singular values only. = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has N = NL + NR + 1 rows and M = N + SQRE >= N columns.

K Output parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, this is the order of the related secular equation. 1 <= K <=N.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry D contains the singular values of the two submatrices to be combined. On exit D contains the trailing (N-K) updated singular values (those which were deflated) sorted into increasing order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (M). On exit Z contains the updating row vector in the secular equation.

ZW Output parameter.

ZW is DOUBLE PRECISION

ZW is an array, dimension (M). Workspace for Z.

VF Input and output parameter.

VF is DOUBLE PRECISION

VF is an array, dimension (M). On entry, VF(1:NL+1) contains the first components of all right singular vectors of the upper block; and VF(NL+2:M) contains the first components of all right singular vectors of the lower block. On exit, VF contains the first components of all right singular vectors of the bidiagonal matrix.

VFW Output parameter.

VFW is DOUBLE PRECISION

VFW is an array, dimension (M). Workspace for VF.

VL Input and output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (M). On entry, VL(1:NL+1) contains the last components of all right singular vectors of the upper block; and VL(NL+2:M) contains the last components of all right singular vectors of the lower block. On exit, VL contains the last components of all right singular vectors of the bidiagonal matrix.

VLW Output parameter.

VLW is DOUBLE PRECISION

VLW is an array, dimension (M). Workspace for VL.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

Contains the diagonal element associated with the added row.

BETA Input parameter.

BETA is DOUBLE PRECISION

Contains the off-diagonal element associated with the added row.

DSIGMA Output parameter.

DSIGMA is DOUBLE PRECISION

DSIGMA is an array, dimension (N). Contains a copy of the diagonal elements (K-1 singular values and one zero) in the secular equation.

IDX Output parameter.

IDX is INTEGER array, dimension (N)

This will contain the permutation used to sort the contents of D into ascending order.

IDXP Output parameter.

IDXP is INTEGER array, dimension (N)

This will contain the permutation used to place deflated values of D at the end of the array. On output IDXP(2:K) points to the nondeflated D-values and IDXP(K+1:N) points to the deflated singular values.

IDXQ Input parameter.

IDXQ is INTEGER array, dimension (N)

This contains the permutation which separately sorts the two sub-problems in D into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have NL+1 added to their values.

PERM Output parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) to be applied to each singular block. Not referenced if ICOMPQ = 0.

GIVPTR Output parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem. Not referenced if ICOMPQ = 0.

GIVCOL Output parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL Input parameter.

LDGCOL is INTEGER

The leading dimension of GIVCOL, must be at least N.

GIVNUM Output parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (LDGNUM, 2). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM Input parameter.

LDGNUM is INTEGER

The leading dimension of GIVNUM, must be at least N.

C Output parameter.

C is DOUBLE PRECISION

C contains garbage if SQRE =0 and the C-value of a Givens rotation related to the right null space if SQRE = 1.

S Output parameter.

S is DOUBLE PRECISION

S contains garbage if SQRE =0 and the S-value of a Givens rotation related to the right null space if SQRE = 1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *slasd7*.

4.17.336 dlasd8

dlasd8 finds the square roots of the roots of the secular equation, as defined by the values in DSIGMA and Z. It makes the appropriate calls to DLASD4, and stores, for each element in D, the distance to its two nearest poles (elements in DSIGMA). It also updates the arrays VF and VL, the first and last components of all the right singular vectors of the original bidiagonal matrix.

dlasd8 is called from DLASD6.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasd8(ICOMPQ, K, D, Z, VF, VL, DIFL, DIFR, LDDIFR, DSIGMA, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dlasd8_(const armpl_int_t *icompq, const armpl_int_t *k, double *d,
             double *z, double *vf, double *vl, double *difl, double *difr,
             const armpl_int_t *lddifr, double *dsigma, double *work,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in factored form in the calling routine: = 0: Compute singular values only. = 1: Compute singular vectors in factored form as well.

K Input parameter.

K is INTEGER

The number of terms in the rational function to be solved by DLASD4. K >= 1.

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (K). On output, D contains the updated singular values.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (K). On entry, the first K elements of this array contain the components of the deflation-adjusted updating row vector. On exit, Z is updated.

VF Input and output parameter.

VF is DOUBLE PRECISION

VF is an array, dimension (K). On entry, VF contains information passed through DBEDE8. On exit, VF contains the first K components of the first components of all right singular vectors of the bidiagonal matrix.

VL Input and output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (K). On entry, VL contains information passed through DBEDE8. On exit, VL contains the first K components of the last components of all right singular vectors of the bidiagonal matrix.

DIFL Output parameter.

DIFL is DOUBLE PRECISION

DIFL is an array, dimension (K). On exit, DIFL(I) = D(I) - DSIGMA(I).

DIFR Output parameter.

DIFR is DOUBLE PRECISION

DIFR is an array,. dimension (LDDIFR, 2) if ICOMPQ = 1 and dimension (K) if ICOMPQ = 0. On exit, DIFR(I,1) = D(I) - DSIGMA(I+1), DIFR(K,1) is not defined and will not be referenced.

If ICOMPQ = 1, DIFR(1:K,2) is an array containing the normalizing factors for the right singular vector matrix.

LDDIFR Input parameter.

LDDIFR is INTEGER

The leading dimension of DIFR, must be at least K.

DSIGMA Input and output parameter.

DSIGMA is DOUBLE PRECISION

DSIGMA is an array, dimension (K). On entry, the first K elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation. On exit, the elements of DSIGMA may be very slightly altered in value.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*K) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *slasd8*.

4.17.337 dlasda

Using a divide and conquer approach, dlasda computes the singular value decomposition (SVD) of a real upper bidiagonal N-by-M matrix B with diagonal D and offdiagonal E, where M = N + SQRE. The algorithm computes the singular values in the SVD B = U * S * VT. The orthogonal matrices U and VT are optionally computed in compact form.

A related subroutine, DLASD0, computes the singular values and the singular vectors in explicit form.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasda(ICOMPQ, SMLSIZ, N, SQRE, D, E, U, LDU, VT, K, DIFL, DIFR, Z,
                  POLES, GIVPTR, GIVCOL, LDGCOL, PERM, GIVNUM, C, S, WORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlasda_(const armpl_int_t *icompq, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *sqre, double *d,
             const double *e, double *u, const armpl_int_t *ldu, double *vt,
             armpl_int_t *k, double *difl, double *difr, double *z,
             double *poles, armpl_int_t *givptr, armpl_int_t *givcol,
             const armpl_int_t *ldgcol, armpl_int_t *perm, double *givnum,
             double *c, double *s, double *work, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in compact form, as follows = 0: Compute singular values only. = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

SMLSIZ Input parameter.

SMLSIZ is INTEGER

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

N is INTEGER

The row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array D.

SQRE Input parameter.

SQRE is INTEGER

Specifies the column dimension of the bidiagonal matrix. = 0: The bidiagonal matrix has column dimension M = N; = 1: The bidiagonal matrix has column dimension M = N + 1.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry D contains the main diagonal of the bidiagonal matrix. On exit D, if INFO = 0, contains its singular values.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (M-1). Contains the subdiagonal entries of the bidiagonal matrix. On exit, E has been destroyed.

U Output parameter.

U is DOUBLE PRECISION

U is an array,. dimension (LDU, SMLSIZ) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, U contains the left singular vector matrices of all subproblems at the bottom level.

LDU Input parameter.

LDU is INTEGER, LDU = > N.

The leading dimension of arrays U, VT, DIFL, DIFR, POLES, GIVNUM, and Z.

VT Output parameter.

VT is DOUBLE PRECISION

VT is an array,. dimension (LDU, SMLSIZ+1) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, VT^T contains the right singular vector matrices of all subproblems at the bottom level.

K Output parameter.

K is INTEGER array,

dimension (N) if ICOMPQ = 1 and dimension 1 if ICOMPQ = 0. If ICOMPQ = 1, on exit, K(I) is the dimension of the I-th secular equation on the computation tree.

DIFL Output parameter.

DIFL is DOUBLE PRECISION

DIFL is an array, dimension (LDU, NLVL),. where NLVL = floor(log_2 (N/SMLSIZ))).

DIFR Output parameter.

DIFR is DOUBLE PRECISION

DIFR is an array,. dimension (LDU, 2 * NLVL) if ICOMPQ = 1 and dimension (N) if ICOMPQ = 0. If ICOMPQ = 1, on exit, DIFL(1:N, I) and DIFR(1:N, 2 * I - 1) record distances between singular values on the I-th level and singular values on the (I -1)-th level, and DIFR(1:N, 2 * I) contains the normalizing factors for the right singular vector matrix. See DLASD8 for details.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array,. dimension (LDU, NLVL) if ICOMPQ = 1 and dimension (N) if ICOMPQ = 0. The first K elements of Z(1, I) contain the components of the deflation-adjusted updating row vector for subproblems on the I-th level.

POLES Output parameter.

POLES is DOUBLE PRECISION

POLES is an array,. dimension (LDU, 2 * NLVL) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, POLES(1, 2*I - 1) and POLES(1, 2*I) contain the new and old singular values involved in the secular equations on the I-th level.

GIVPTR Output parameter.

GIVPTR is INTEGER array,

dimension (N) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, GIVPTR(I) records the number of Givens rotations performed on the I-th problem on the computation tree.

GIVCOL Output parameter.

GIVCOL is INTEGER array,

dimension (LDGCOL, 2 * NLVL) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I, GIVCOL(1, 2 *I - 1) and GIVCOL(1, 2 *I) record the locations of Givens rotations performed on the I-th level on the computation tree.

LDGCOL Input parameter.

LDGCOL is INTEGER, LDGCOL = > N.

The leading dimension of arrays GIVCOL and PERM.

PERM Output parameter.

PERM is INTEGER array,

dimension (LDGCOL, NLVL) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, PERM(1, I) records permutations done on the I-th level of the computation tree.

GIVNUM Output parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array,. dimension (LDU, 2 * NLVL) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I, GIVNUM(1, 2 *I - 1) and GIVNUM(1, 2 *I) record the C- and S- values of Givens rotations performed on the I-th level on the computation tree.

C Output parameter.

C is DOUBLE PRECISION

C is an array,. dimension (N) if ICOMPQ = 1, and dimension 1 if ICOMPQ = 0. If ICOMPQ = 1 and the I-th subproblem is not square, on exit, C(I) contains the C-value of a Givens rotation related to the right null space of the I-th subproblem.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N) if. ICOMPQ = 1, and dimension 1 if ICOMPQ = 0. If ICOMPQ = 1 and the I-th subproblem is not square, on exit, S(I) contains the S-value of a Givens rotation related to the right null space of the I-th subproblem.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (6 * N + (SMLSIZ + 1)*(SMLSIZ + 1)).

IWORK Output parameter.

IWORK is INTEGER array, dimension (7*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *slasda*.

4.17.338 dlasdq

dlasdq computes the singular value decomposition (SVD) of a real (upper or lower) bidiagonal matrix with diagonal D and offdiagonal E, accumulating the transformations if desired. Letting B denote the input bidiagonal matrix, the algorithm computes orthogonal matrices Q and P such that B = Q * S * P^T (P^T denotes the transpose of P). The singular values S are overwritten on D.

The input matrix U is changed to U * Q if desired. The input matrix VT is changed to P^T * VT if desired. The input matrix C is changed to Q^T * C if desired.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3, for a detailed description of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasdq(UPLO, SQRE, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU, C,
                  LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlasdq_(const char *uplo, const armpl_int_t *sqre, const armpl_int_t *n,
             const armpl_int_t *ncvt, const armpl_int_t *nru,
             const armpl_int_t *ncc, double *d, double *e, double *vt,
             const armpl_int_t *ldvt, double *u, const armpl_int_t *ldu,
             double *c, const armpl_int_t *ldc, double *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the input bidiagonal matrix is upper or lower bidiagonal, and whether it is square are not. UPLO = 'U' or 'u' B is upper bidiagonal. UPLO = 'L' or 'l' B is lower bidiagonal.

SQRE Input parameter.

SQRE is INTEGER

= 0: then the input matrix is N-by-N. = 1: then the input matrix is N-by-(N+1) if UPLU = 'U' and (N+1)-by-N if UPLU = 'L'.

The bidiagonal matrix has N = NL + NR + 1 rows and M = N + SQRE >= N columns.

N Input parameter.

N is INTEGER

On entry, N specifies the number of rows and columns in the matrix. N must be at least 0.

NCVT Input parameter.

NCVT is INTEGER

On entry, NCVT specifies the number of columns of the matrix VT. NCVT must be at least 0.

NRU Input parameter.

NRU is INTEGER

On entry, NRU specifies the number of rows of the matrix U. NRU must be at least 0.

NCC Input parameter.

NCC is INTEGER

On entry, NCC specifies the number of columns of the matrix C. NCC must be at least 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, D contains the diagonal entries of the bidiagonal matrix whose SVD is desired. On normal exit, D contains the singular values in ascending order.

E Input and output parameter.

E is DOUBLE PRECISION array.

dimension is (N-1) if SQRE = 0 and N if SQRE = 1. On entry, the entries of E contain the offdiagonal entries of the bidiagonal matrix whose SVD is desired. On normal exit, E will contain 0. If the algorithm does not converge, D and E will contain the diagonal and superdiagonal entries of a bidiagonal matrix orthogonally equivalent to the one given as input.

VT Input and output parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDVT, NCVT). On entry, contains a matrix which on exit has been premultiplied by P^T , dimension N-by-NCVT if SQRE = 0 and (N+1)-by-NCVT if SQRE = 1 (not referenced if NCVT=0).

LDVT Input parameter.

LDVT is INTEGER

On entry, LDVT specifies the leading dimension of VT as declared in the calling (sub) program. LDVT must be at least 1. If NCVT is nonzero LDVT must also be at least N.

U Input and output parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, N). On entry, contains a matrix which on exit has been postmultiplied by Q, dimension NRU-by-N if SQRE = 0 and NRU-by-(N+1) if SQRE = 1 (not referenced if NRU=0).

LDU Input parameter.

LDU is INTEGER

On entry, LDU specifies the leading dimension of U as declared in the calling (sub) program. LDU must be at least max(1, NRU) .

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, NCC). On entry, contains an N-by-NCC matrix which on exit has been premultiplied by Q^T dimension N-by-NCC if SQRE = 0 and (N+1)-by-NCC if SQRE = 1 (not referenced if NCC=0).

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the leading dimension of C as declared in the calling (sub) program. LDC must be at least 1. If NCC is nonzero, LDC must also be at least N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N). Workspace. Only referenced if one of NCVT, NRU, or NCC is nonzero, and if N is at least 2.

INFO Output parameter.

INFO is INTEGER

On exit, a value of 0 indicates a successful exit. If INFO < 0, argument number -INFO is illegal. If INFO > 0, the algorithm did not converge, and INFO specifies how many superdiagonals did not converge.

Related Information

For this routine in other precisions, please see *slasdq*.

4.17.339 dlasdt

dlasdt creates a tree of subproblems for bidiagonal divide and conquer.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasdt(N, LVL, ND, INODE, NDIML, NDIMR, MSUB)
```

C specification:

```
#include "armpl.h"

void dlasdt_(const armpl_int_t *n, armpl_int_t *lvl, armpl_int_t *nd,
             armpl_int_t *inode, armpl_int_t *ndiml, armpl_int_t *ndimr,
             const armpl_int_t *msub);
```

Parameters

N Input parameter.

N is INTEGER

On entry, the number of diagonal elements of the bidiagonal matrix.

LVL Output parameter.

LVL is INTEGER

On exit, the number of levels on the computation tree.

ND Output parameter.

ND is INTEGER

On exit, the number of nodes on the tree.

INODE Output parameter.

INODE is INTEGER array, dimension (N)

On exit, centers of subproblems.

NDIML Output parameter.

NDIML is INTEGER array, dimension (N)

On exit, row dimensions of left children.

NDIMR Output parameter.

NDIMR is INTEGER array, dimension (N)

On exit, row dimensions of right children.

MSUB Input parameter.

MSUB is INTEGER

On entry, the maximum row dimension each subproblem at the bottom of the tree can be of.

Related Information

For this routine in other precisions, please see *slasdt*.

4.17.340 dlaset

dlaset initializes an m-by-n matrix A to BETA on the diagonal and ALPHA on the offdiagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaset(UPLO, M, N, ALPHA, BETA, A, LDA)
```

C specification:

```
#include "armpl.h"

void dlaset_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const double *alpha, const double *beta, double *a,
             const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be set. = 'U': Upper triangular part is set; the strictly lower triangular part of A is not changed. = 'L': Lower triangular part is set; the strictly upper triangular part of A is not changed. Otherwise: All of the matrix A is set.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

The constant to which the offdiagonal elements are to be set.

BETA Input parameter.

BETA is DOUBLE PRECISION

The constant to which the diagonal elements are to be set.

A Output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On exit, the leading m-by-n submatrix of A is set as follows:

if UPLO = 'U', A(i,j) = ALPHA, 1<=i<=j-1, 1<=j<=n, if UPLO = 'L', A(i,j) = ALPHA, j+1<=i<=m, 1<=j<=n, otherwise, A(i,j) = ALPHA, 1<=i<=m, 1<=j<=n, i.ne.j,

and, for all UPLO, A(i,i) = BETA, 1<=i<=min(m,n).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

For this routine in other precisions, please see *claset*, *slaset* and *zlaset*. It also exists with a native C interface as *LAPACKE_dlaset*.

4.17.341 dlasq1

`dlasq1` computes the singular values of a real N-by-N bidiagonal matrix with diagonal D and off-diagonal E. The singular values are computed to high relative accuracy, in the absence of denormalization, underflow and overflow. The algorithm was first presented in

"Accurate singular values and differential qd algorithms" by K. V. Fernando and B. N. Parlett, Numer. Math., Vol-67, No. 2, pp. 191-230, 1994,

and the present implementation is described in "An implementation of the dqds Algorithm (Positive Case)", LAPACK Working Note.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasq1(N, D, E, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlasq1_(const armpl_int_t *n, double *d, double *e, double *work,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows and columns in the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, D contains the diagonal elements of the bidiagonal matrix whose SVD is desired. On normal exit, D contains the singular values in decreasing order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, elements E(1:N-1) contain the off-diagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E is overwritten.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: the algorithm failed = 1, a split was marked by a positive value in E = 2, current block of Z not diagonalized after 100*N iterations (in inner while loop) On exit D and E represent a matrix with the same singular values which the calling subroutine could use to finish the computation, or even feed back into DLASQ1 = 3, termination criterion of outer while loop not met (program created more than N unreduced blocks)

Related Information

For this routine in other precisions, please see *slasq1*.

4.17.342 dlasq2

dlasq2 computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the qd array Z to high relative accuracy are computed to high relative accuracy, in the absence of denormalization, underflow and overflow.

To see the relation of Z to the tridiagonal matrix, let L be a unit lower bidiagonal matrix with subdiagonals Z(2,4,6,,..) and let U be an upper bidiagonal matrix with 1's above and diagonal Z(1,3,5,,..). The tridiagonal is L*U or, if you prefer, the symmetric tridiagonal to which it is similar.

Note : dlasq2 defines a logical variable, IEEE, which is true on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs, and false otherwise. This variable is passed to DLASQ3.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasq2(N, Z, INFO)
```

C specification:

```
#include "armpl.h"

void dlasq2_(const armpl_int_t *n, double *z, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows and columns in the matrix. N >= 0.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (4* N). On entry Z holds the qd array. On exit, entries 1 to N hold the eigenvalues in decreasing order, Z(2*N+1) holds the trace, and Z(2*N+2) holds the sum of the eigenvalues. If N > 2, then Z(2*N+3) holds the iteration count, Z(2*N+4) holds NDIVS/NIN^2, and Z(2*N+5) holds the percentage of shifts that failed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if the i-th argument is a scalar and had an illegal value, then INFO = -i, if the i-th argument is an array and the j-entry had an illegal value, then INFO = -(i*100+j) > 0: the algorithm failed = 1, a split was marked by a positive value in E = 2, current block of Z not diagonalized after 100*N iterations (in inner while loop). On exit Z holds a qd array with the same eigenvalues as the given Z. = 3, termination criterion of outer while loop not met (program created more than N unreduced blocks)

Related Information

For this routine in other precisions, please see *slasq2*.

4.17.343 dlasq3

dlasq3 checks for deflation, computes a shift (TAU) and calls dqds. In case of failure it changes shifts, and tries again until output is positive.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasq3(I0, N0, Z, PP, DMIN, SIGMA, DESIG, QMAX, NFAIL, ITER, NDIV,
                  IEEE, TTYPE, DMIN1, DMIN2, DN, DN1, DN2, G, TAU)
```

C specification:

```
#include "armpl.h"

void dlasq3_(const armpl_int_t *i0, const armpl_int_t *n0, const double *z,
             armpl_int_t *pp, double *dmin, double *sigma, double *desig,
             const double *qmax, armpl_int_t *nfail, armpl_int_t *iter,
             armpl_int_t *ndiv, const armpl_int_t *ieee, armpl_int_t *ttype,
             double *dmin1, double *dmin2, double *dn, double *dn1,
             double *dn2, double *g, double *tau);
```

Parameters

I0 Input parameter.

I0 is INTEGER

First index.

N0 Input and output parameter.

N0 is INTEGER

Last index.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (4* N0). Z holds the qd array.

PP Input and output parameter.

PP is INTEGER

PP=0 for ping, PP=1 for pong. PP=2 indicates that flipping was applied to the Z array and that the initial tests for deflation should not be performed.

DMIN Output parameter.

DMIN is DOUBLE PRECISION

Minimum value of d.

SIGMA Output parameter.

SIGMA is DOUBLE PRECISION

Sum of shifts used in current segment.

DESIG Input and output parameter.

DESIG is DOUBLE PRECISION

Lower order part of SIGMA

QMAX Input parameter.

QMAX is DOUBLE PRECISION

Maximum value of q.

NFAIL Input and output parameter.

NFAIL is INTEGER

Increment NFAIL by 1 each time the shift was too big.

ITER Input and output parameter.

ITER is INTEGER

Increment ITER by 1 for each iteration.

NDIV Input and output parameter.

NDIV is INTEGER

Increment NDIV by 1 for each division.

IEEE Input parameter.

IEEE is LOGICAL

Flag for IEEE or non IEEE arithmetic (passed to DLASQ5).

TTYPE Input and output parameter.

TTYPE is INTEGER

Shift type.

DMIN1 Input and output parameter.

DMIN1 is DOUBLE PRECISION

DMIN2 Input and output parameter.

DMIN2 is DOUBLE PRECISION

DN Input and output parameter.

DN is DOUBLE PRECISION

DN1 Input and output parameter.

DN1 is DOUBLE PRECISION

DN2 Input and output parameter.

DN2 is DOUBLE PRECISION

G Input and output parameter.

G is DOUBLE PRECISION

TAU Input and output parameter.

TAU is DOUBLE PRECISION

These are passed as arguments in order to save their values between calls to DLASQ3.

Related Information

For this routine in other precisions, please see *slasq3*.

4.17.344 dlasq4

dlasq4 computes an approximation TAU to the smallest eigenvalue using values of d from the previous transform.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasq4(I0, N0, Z, PP, N0IN, DMIN, DMIN1, DMIN2, DN, DN1, DN2, TAU,
                  TTYPE, G)
```

C specification:

```
#include "armpl.h"

void dlasq4_(const armpl_int_t *i0, const armpl_int_t *n0, const double *z,
             const armpl_int_t *pp, armpl_int_t *n0in, const double *dmin,
             const double *dmin1, const double *dmin2, const double *dn,
             const double *dn1, const double *dn2, double *tau,
             armpl_int_t *ttype, double *g);
```

Parameters

I0 Input parameter.

I0 is INTEGER

First index.

N0 Input parameter.

N0 is INTEGER

Last index.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (4* N0). Z holds the qd array.

PP Input parameter.

PP is INTEGER

PP=0 for ping, PP=1 for pong.

N0IN Input parameter.

N0IN is INTEGER

The value of N0 at start of EIGTEST.

DMIN Input parameter.

DMIN is DOUBLE PRECISION

Minimum value of d.

DMIN1 Input parameter.

DMIN1 is DOUBLE PRECISION

Minimum value of d, excluding D(N0).

DMIN2 Input parameter.

DMIN2 is DOUBLE PRECISION

Minimum value of d, excluding D(N0) and D(N0-1).

DN Input parameter.

DN is DOUBLE PRECISION

d(N)

DN1 Input parameter.

DN1 is DOUBLE PRECISION

d(N-1)

DN2 Input parameter.

DN2 is DOUBLE PRECISION

d(N-2)

TAU Output parameter.

TAU is DOUBLE PRECISION

This is the shift.

TTYPE Output parameter.

TTYPE is INTEGER

Shift type.

G Input and output parameter.

G is DOUBLE PRECISION

G is passed as an argument in order to save its value between calls to DLASQ4.

Related Information

For this routine in other precisions, please see *slasq4*.

4.17.345 dlasq5

dlasq5 computes one dqds transform in ping-pong form, one version for IEEE machines another for non IEEE machines.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasq5(I0, N0, Z, PP, TAU, SIGMA, DMIN, DMIN1, DMIN2, DN, DNM1,
                  DNM2, IEEE, EPS)
```

C specification:

```
#include "armpl.h"

void dlasq5_(const armpl_int_t *i0, const armpl_int_t *n0, const double *z,
             const armpl_int_t *pp, const double *tau, const double *sigma,
             double *dmin, double *dmin1, double *dmin2, double *dn,
             double *dnm1, double *dnm2, const armpl_int_t *ieee,
             const double *eps);
```

Parameters

I0 Input parameter.

I0 is INTEGER

First index.

N0 Input parameter.

N0 is INTEGER

Last index.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (4*N). Z holds the qd array. EMIN is stored in Z(4*N0) to avoid an extra argument.

PP Input parameter.

PP is INTEGER

PP=0 for ping, PP=1 for pong.

TAU Input parameter.

TAU is DOUBLE PRECISION

This is the shift.

SIGMA Input parameter.

SIGMA is DOUBLE PRECISION

This is the accumulated shift up to this step.

DMIN Output parameter.

DMIN is DOUBLE PRECISION

Minimum value of d.

DMIN1 Output parameter.

DMIN1 is DOUBLE PRECISION

Minimum value of d, excluding D(N0).

DMIN2 Output parameter.

DMIN2 is DOUBLE PRECISION

Minimum value of d, excluding D(N0) and D(N0-1).

DN Output parameter.

DN is DOUBLE PRECISION

d(N0), the last value of d.

DNM1 Output parameter.

DNM1 is DOUBLE PRECISION

d(N0-1).

DNM2 Output parameter.

DNM2 is DOUBLE PRECISION

d(N0-2).

IEEE Input parameter.

IEEE is LOGICAL

Flag for IEEE or non IEEE arithmetic.

EPS Input parameter.

EPS is DOUBLE PRECISION

This is the value of epsilon used.

Related Information

For this routine in other precisions, please see *slasq5*.

4.17.346 dlasq6

dlasq6 computes one dqd (shift equal to zero) transform in ping-pong form, with protection against underflow and overflow.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasq6(I0, N0, Z, PP, DMIN, DMIN1, DMIN2, DN, DNM1, DNM2)
```

C specification:

```
#include "armpl.h"

void dlasq6_(const armpl_int_t *i0, const armpl_int_t *n0, const double *z,
             const armpl_int_t *pp, double *dmin, double *dmin1,
             double *dmin2, double *dn, double *dnm1, double *dnm2);
```

Parameters

I0 Input parameter.

I0 is INTEGER

First index.

N0 Input parameter.

N0 is INTEGER

Last index.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (4*N). Z holds the qd array. EMIN is stored in Z(4*N0) to avoid an extra argument.

PP Input parameter.

PP is INTEGER

PP=0 for ping, PP=1 for pong.

DMIN Output parameter.

DMIN is DOUBLE PRECISION

Minimum value of d.

DMIN1 Output parameter.

DMIN1 is DOUBLE PRECISION

Minimum value of d, excluding D(N0).

DMIN2 Output parameter.

DMIN2 is DOUBLE PRECISION

Minimum value of d, excluding D(N0) and D(N0-1).

DN Output parameter.

DN is DOUBLE PRECISION

d(N0), the last value of d.

DNM1 Output parameter.

DNM1 is DOUBLE PRECISION

d(N0-1).

DNM2 Output parameter.

DNM2 is DOUBLE PRECISION

d(N0-2).

Related Information

For this routine in other precisions, please see *slasq6*.

4.17.347 dlasr

`dlasr` applies a sequence of plane rotations to a real matrix A, from either the left or the right.

When SIDE = 'L', the transformation takes the form

```
A := P*A
```

and when SIDE = 'R', the transformation takes the form

```
A := A*P**T
```

where P is an orthogonal matrix consisting of a sequence of z plane rotations, with z = M when SIDE = 'L' and z = N when SIDE = 'R', and P^T is the transpose of P.

When DIRECT = 'F' (Forward sequence), then

```
P = P(z-1) * ... * P(2) * P(1)
```

and when DIRECT = 'B' (Backward sequence), then

```
P = P(1) * P(2) * ... * P(z-1)
```

where P(k) is a plane rotation matrix defined by the 2-by-2 rotation

```
R(k) = (  c(k)  s(k) )
     = ( -s(k)  c(k) ).
```

When PIVOT = 'V' (Variable pivot), the rotation is performed for the plane (k,k+1), i.e., P(k) has the form

```
P(k) = (  1                                          )
       (       ...                                   )
       (              1                              )
       (                    c(k)  s(k)               )
       (                   -s(k)  c(k)               )
       (                             1               )
       (                                  ...        )
       (                                        1    )
```

where R(k) appears as a rank-2 modification to the identity matrix in rows and columns k and k+1.

When PIVOT = 'T' (Top pivot), the rotation is performed for the plane (1,k+1), so P(k) has the form

```
P(k) = (  c(k)                    s(k)               )
       (         1                                   )
       (              ...                            )
       (                     1                       )
       ( -s(k)                    c(k)               )
       (                                 1           )
       (                                      ...    )
       (                                            1 )
```

where R(k) appears in rows and columns 1 and k+1.

Similarly, when PIVOT = 'B' (Bottom pivot), the rotation is performed for the plane (k,z), giving P(k) the form

```
P(k) = ( 1                                           )
       (       ...                                   )
       (              1                              )
       (                    c(k)               s(k)  )
       (                           1                )
       (                                ...         )
       (                                     1      )
       (                   -s(k)               c(k)  )
```

where R(k) appears in rows and columns k and z. The rotations are performed without ever forming P(k) explicitly.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasr(SIDE, PIVOT, DIRECT, M, N, C, S, A, LDA)
```

C specification:

```
#include "armpl.h"

void dlasr_(const char *side, const char *pivot, const char *direct,
            const armpl_int_t *m, const armpl_int_t *n, const double *c,
            const double *s, double *a, const armpl_int_t *lda, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

Specifies whether the plane rotation matrix P is applied to A on the left or the right. = 'L': Left, compute A := P*A = 'R': Right, compute A:= A*P^T

PIVOT Input parameter.

PIVOT is CHARACTER*1

Specifies the plane for which P(k) is a plane rotation matrix. = 'V': Variable pivot, the plane (k,k+1) = 'T': Top pivot, the plane (1,k+1) = 'B': Bottom pivot, the plane (k,z)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies whether P is a forward or backward sequence of plane rotations. = 'F': Forward, P = P(z-1)*...*P(2)*P(1) = 'B': Backward, P = P(1)*P(2)*...*P(z-1)

M Input parameter.

M is INTEGER

The number of rows of the matrix A. If m <= 1, an immediate return is effected.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. If n <= 1, an immediate return is effected.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' The cosines c(k) of the plane rotations.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' The sines s(k) of the plane rotations. The 2-by-2 plane rotation part of the matrix P(k), R(k), has the form R(k) = (c(k) s(k)) (-s(k) c(k)).

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The M-by-N matrix A. On exit, A is overwritten by P* A if SIDE = 'R' or by A*P^T if SIDE = 'L'.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

For this routine in other precisions, please see *clasr*, *slasr* and *zlasr*.

4.17.348 dlasrt

Sort the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of size <= 20. Dimension of STACK limits N to about 2**32.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasrt(ID, N, D, INFO)
```

C specification:

```
#include "armpl.h"

void dlasrt_(const char *id, const armpl_int_t *n, double *d,
             armpl_int_t *info, ... );
```

Parameters

ID Input parameter.

ID is CHARACTER*1

= 'I': sort D in increasing order; = 'D': sort D in decreasing order.

N Input parameter.

N is INTEGER

The length of the array D.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the array to be sorted. On exit, D has been sorted into increasing order (D(1) <= ... <= D(N)) or into decreasing order (D(1) >= ... >= D(N)), depending on ID.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *slasrt*. It also exists with a native C interface as *LAPACKE_dlasrt*.

4.17.349 dlassq

dlassq returns the values scl and smsq such that

```
( scl**2 )*smsq = x( 1 )**2 +...+ x( n )**2 + ( scale**2 )*sumsq,
```

where x(i) = X(1 + (i - 1)*INCX). The value of sumsq is assumed to be non-negative and scl returns the value

```
scl = max( scale, abs( x( i ) ) ).
```

scale and sumsq must be supplied in SCALE and SUMSQ and scl and smsq are overwritten on SCALE and SUMSQ respectively.

The routine makes only one pass through the vector x.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlassq(N, X, INCX, SCALE, SUMSQ)
```

C specification:

```
#include "armpl.h"

void dlassq_(const armpl_int_t *n, const double *x, const armpl_int_t *incx,
             double *scale, double *sumsq);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements to be used from the vector X.

X Input parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). The vector for which a scaled sum of squares is computed. x(i) = X(1 + (i - 1)* INCX), 1 <= i <= n.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of the vector X. INCX > 0.

SCALE Input and output parameter.

SCALE is DOUBLE PRECISION

On entry, the value scale in the equation above. On exit, SCALE is overwritten with scl , the scaling factor for the sum of squares.

SUMSQ Input and output parameter.

SUMSQ is DOUBLE PRECISION

On entry, the value sumsq in the equation above. On exit, SUMSQ is overwritten with smsq , the basic sum of squares from which scl has been factored out.

Related Information

For this routine in other precisions, please see *classq*, *slassq* and *zlassq*. It also exists with a native C interface as *LAPACKE_dlassq*.

4.17.350 dlasv2

dlasv2 computes the singular value decomposition of a 2-by-2 triangular matrix

```
[  F   G  ]
[  0   H  ].
```

On return, abs(SSMAX) is the larger singular value, abs(SSMIN) is the smaller singular value, and (CSL,SNL) and (CSR,SNR) are the left and right singular vectors for abs(SSMAX), giving the decomposition

```
[ CSL  SNL ] [  F   G  ] [ CSR -SNR ]  =  [ SSMAX   0   ]
[-SNL  CSL ] [  0   H  ] [ SNR  CSR ]     [  0    SSMIN ].
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasv2(F, G, H, SSMIN, SSMAX, SNR, CSR, SNL, CSL)
```

C specification:

```
#include "armpl.h"

void dlasv2_(const double *f, const double *g, const double *h, double *ssmin,
             double *ssmax, double *snr, double *csr, double *snl,
             double *csl);
```

Parameters

F Input parameter.

F is DOUBLE PRECISION

The (1,1) element of the 2-by-2 matrix.

G Input parameter.

G is DOUBLE PRECISION

The (1,2) element of the 2-by-2 matrix.

H Input parameter.

H is DOUBLE PRECISION

The (2,2) element of the 2-by-2 matrix.

SSMIN Output parameter.

SSMIN is DOUBLE PRECISION

abs(SSMIN) is the smaller singular value.

SSMAX Output parameter.

SSMAX is DOUBLE PRECISION

abs(SSMAX) is the larger singular value.

SNL Output parameter.

SNL is DOUBLE PRECISION

CSL Output parameter.

CSL is DOUBLE PRECISION

The vector (CSL, SNL) is a unit left singular vector for the singular value abs(SSMAX).

SNR Output parameter.

SNR is DOUBLE PRECISION

CSR Output parameter.

CSR is DOUBLE PRECISION

The vector (CSR, SNR) is a unit right singular vector for the singular value abs(SSMAX).

Related Information

For this routine in other precisions, please see *slasv2*.

4.17.351 dlaswlq

dlaswlq computes a blocked Short-Wide LQ factorization of a M-by-N matrix A, where N >= M: A = L * Q

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaswlq(M, N, MB, NB, A, LDA, T, LDT, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlaswlq_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *mb, const armpl_int_t *nb, double *a,
              const armpl_int_t *lda, double *t, const armpl_int_t *ldt,
              double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= M >= 0.

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. M >= MB >= 1

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. NB > M.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the N-by-N lower triangular matrix L; the elements above the diagonal represent Q by the rows of blocked V (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array,. dimension (LDT, N * Number_of_row_blocks) where Number_of_row_blocks = CEIL((N-M)/(NB-M)) The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details below.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

(workspace) DOUBLE PRECISION

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

The dimension of the array WORK. LWORK >= MB*M.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *claswlq*, *slaswlq* and *zlaswlq*.

4.17.352 dlaswp

`dlaswp` performs a series of row interchanges on the matrix A. One row interchange is initiated for each of rows K1 through K2 of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlaswp(N, A, LDA, K1, K2, IPIV, INCX)
```

C specification:

```
#include "armpl.h"

void dlaswp_(const armpl_int_t *n, double *a, const armpl_int_t *lda,
             const armpl_int_t *k1, const armpl_int_t *k2,
             const armpl_int_t *ipiv, const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the matrix of column dimension N to which the row interchanges will be applied. On exit, the permuted matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A.

K1 Input parameter.

K1 is INTEGER

The first element of IPIV for which a row interchange will be done.

K2 Input parameter.

K2 is INTEGER

(K2-K1+1) is the number of elements of IPIV for which a row interchange will be done.

IPIV Input parameter.

IPIV is INTEGER array, dimension (K1+(K2-K1)*abs(INCX))

The vector of pivot indices. Only the elements in positions K1 through K1+(K2-K1)*abs(INCX) of IPIV are accessed. IPIV(K1+(K-K1)*abs(INCX)) = L implies rows K and L are to be interchanged.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of IPIV. If INCX is negative, the pivots are applied in reverse order.

Related Information

For this routine in other precisions, please see *claswp*, *slaswp* and *zlaswp*. It also exists with a native C interface as *LAPACKE_dlaswp*.

4.17.353 dlasy2

`dlasy2` solves for the N1 by N2 matrix X, 1 <= N1,N2 <= 2, in

```
op(TL)*X + ISGN*X*op(TR) = SCALE*B,
```

where TL is N1 by N1, TR is N2 by N2, B is N1 by N2, and ISGN = 1 or -1. op(T) = T or T^T , where T^T denotes the transpose of T.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasy2(LTRANL, LTRANR, ISGN, N1, N2, TL, LDTL, TR, LDTR, B, LDB,
                  SCALE, X, LDX, XNORM, INFO)
```

C specification:

```
#include "armpl.h"

void dlasy2_(const armpl_int_t *ltranl, const armpl_int_t *ltranr,
             const armpl_int_t *isgn, const armpl_int_t *n1,
             const armpl_int_t *n2, const double *tl, const armpl_int_t *ldtl,
             const double *tr, const armpl_int_t *ldtr, const double *b,
             const armpl_int_t *ldb, double *scale, double *x,
             const armpl_int_t *ldx, double *xnorm, armpl_int_t *info);
```

Parameters

LTRANL Input parameter.

LTRANL is LOGICAL

On entry, LTRANL specifies the op(TL): = .FALSE., op(TL) = TL, = .TRUE., op(TL) = TL^T .

LTRANR Input parameter.

LTRANR is LOGICAL

On entry, LTRANR specifies the op(TR): = .FALSE., op(TR) = TR, = .TRUE., op(TR) = TR^T .

ISGN Input parameter.

ISGN is INTEGER

On entry, ISGN specifies the sign of the equation as described before. ISGN may only be 1 or -1.

N1 Input parameter.

N1 is INTEGER

On entry, N1 specifies the order of matrix TL. N1 may only be 0, 1 or 2.

N2 Input parameter.

N2 is INTEGER

On entry, N2 specifies the order of matrix TR. N2 may only be 0, 1 or 2.

TL Input parameter.

TL is DOUBLE PRECISION

TL is an array, dimension (LDTL,2). On entry, TL contains an N1 by N1 matrix.

LDTL Input parameter.

LDTL is INTEGER

The leading dimension of the matrix TL. LDTL >= max(1, N1).

TR Input parameter.

TR is DOUBLE PRECISION

TR is an array, dimension (LDTR,2). On entry, TR contains an N2 by N2 matrix.

LDTR Input parameter.

LDTR is INTEGER

The leading dimension of the matrix TR. LDTR >= max(1, N2).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB,2). On entry, the N1 by N2 matrix B contains the right-hand side of the equation.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the matrix B. LDB >= max(1, N1).

SCALE Output parameter.

SCALE is DOUBLE PRECISION

On exit, SCALE contains the scale factor. SCALE is chosen less than or equal to 1 to prevent the solution overflowing.

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX,2). On exit, X contains the N1 by N2 solution.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the matrix X. LDX >= max(1, N1).

XNORM Output parameter.

XNORM is DOUBLE PRECISION

On exit, XNORM is the infinity-norm of the solution.

INFO Output parameter.

INFO is INTEGER

On exit, INFO is set to 0: successful exit. 1: TL and TR have too close eigenvalues, so TL or TR is perturbed to get a nonsingular equation. NOTE: In the interests of speed, this routine does not check the inputs for errors.

Related Information

For this routine in other precisions, please see *slasy2*.

4.17.354 dlasyf

`dlasyf` computes a partial factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

`dlasyf` is an auxiliary routine called by DSYTRF. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasyf(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void dlasyf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             armpl_int_t *kb, double *a, const armpl_int_t *lda,
             armpl_int_t *ipiv, double *w, const armpl_int_t *ldw,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *clasyf*, *slasyf* and *zlasyf*.

4.17.355 dlasyf_aa

DLATRF_AA factorizes a panel of a real symmetric matrix A using the Aasen's algorithm. The panel consists of a set of NB rows of A when UPLO is U, or a set of NB columns when UPLO is L.

In order to factorize the panel, the Aasen's algorithm requires the last row, or column, of the previous panel. The first row, or column, of A is set to be the first row, or column, of an identity matrix, which is used to factorize the first panel.

The resulting J-th row of U, or J-th column of L, is stored in the (J-1)-th row, or column, of A (without the unit diagonals), while the diagonal and subdiagonal of A are overwritten by those of T.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasyf_aa(UPLO, J1, M, NB, A, LDA, IPIV, H, LDH, WORK)
```

C specification:

```
#include "armpl.h"

void dlasyf_aa_(const char *uplo, const armpl_int_t *j1, const armpl_int_t *m,
                const armpl_int_t *nb, double *a, const armpl_int_t *lda,
                armpl_int_t *ipiv, double *h, const armpl_int_t *ldh,
                double *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

J1 Input parameter.

J1 is INTEGER

The location of the first row, or column, of the panel within the submatrix of A, passed to this routine, e.g., when called by DSYTRF_AA, for the first panel, J1 is 1, while for the remaining panels, J1 is 2.

M Input parameter.

M is INTEGER

The dimension of the submatrix. M >= 0.

NB Input parameter.

NB is INTEGER

The dimension of the panel to be facotorized.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, M) for. the first panel, while dimension (LDA,M+1) for the remaining panels.

On entry, A contains the last row, or column, of the previous panel, and the trailing submatrix of A to be factorized, except for the first panel, only the panel is passed.

On exit, the leading panel is factorized.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (M)

Details of the row and column interchanges, the row and column k were interchanged with the row and column IPIV(k).

H Input and output parameter.

H is DOUBLE PRECISION workspace, dimension (LDH, NB).

LDH Input parameter.

LDH is INTEGER

The leading dimension of the workspace H. LDH >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION workspace, dimension (M).

Related Information

For this routine in other precisions, please see *clasyf_aa*, *slasyf_aa* and *zlasyf_aa*.

4.17.356 dlasyf_rook

DLASYF_ROOK computes a partial factorization of a real symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

DLASYF_ROOK is an auxiliary routine called by DSYTRF_ROOK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasyf_rook(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void dlasyf_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nb, armpl_int_t *kb, double *a,
                  const armpl_int_t *lda, armpl_int_t *ipiv, double *w,
                  const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *clasyf_rook*, *slasyf_rook* and *zlasyf_rook*.

4.17.357 dlat2s

dlat2s converts a DOUBLE PRECISION triangular matrix, SA, to a SINGLE PRECISION triangular matrix, A.

RMAX is the overflow for the SINGLE PRECISION arithmetic DLAS2S checks that all the entries of A are between -RMAX and RMAX. If not the conversion is aborted and a flag is raised.

This is an auxiliary routine so there is no argument checking.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlat2s(UPLO, N, A, LDA, SA, LDSA, INFO)
```

C specification:

```
#include "armpl.h"

void dlat2s_(const char *uplo, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, float *sa, const armpl_int_t *ldsa,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The number of rows and columns of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N triangular coefficient matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

SA Output parameter.

SA is REAL

SA is an array, dimension (LDSA, N). Only the UPLO part of SA is referenced. On exit, if INFO=0, the N-by-N coefficient matrix SA; if INFO>0, the content of the UPLO part of SA is unspecified.

LDSA Input parameter.

LDSA is INTEGER

The leading dimension of the array SA. LDSA >= max(1,M).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. = 1: an entry of the matrix A is greater than the SINGLE PRECISION overflow threshold, in this case, the content of the UPLO part of SA in exit is unspecified.

Related Information

4.17.358 dlatbs

dlatbs solves one of the triangular systems

```
A *x = s*b  or  A**T*x = s*b
```

with scaling to prevent overflow, where A is an upper or lower triangular band matrix. Here A^T denotes the transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine DTBSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlatbs(UPLO, TRANS, DIAG, NORMIN, N, KD, AB, LDAB, X, SCALE, CNORM,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dlatbs_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n, const armpl_int_t *kd,
             const double *ab, const armpl_int_t *ldab, double *x,
             double *scale, double *cnorm, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^T * x = s*b (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of subdiagonals or superdiagonals in the triangular matrix A. KD >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

The scaling factor s for the triangular system A * x = s*b or A^T * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is DOUBLE PRECISION

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than

or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatbs*, *slatbs* and *zlatbs*.

4.17.359 dlatdf

dlatdf uses the LU factorization of the n-by-n matrix Z computed by DGETC2 and computes a contribution to the reciprocal Dif-estimate by solving Z * x = b for x, and choosing the r.h.s. b such that the norm of x is as large as possible. On entry RHS = b holds the contribution from earlier solved sub-systems, and on return RHS = x.

The factorization of Z returned by DGETC2 has the form Z = P*L*U*Q, where P and Q are permutation matrices. L is lower triangular with unit diagonal elements and U is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlatdf(IJOB, N, Z, LDZ, RHS, RDSUM, RDSCAL, IPIV, JPIV)
```

C specification:

```
#include "armpl.h"

void dlatdf_(const armpl_int_t *ijob, const armpl_int_t *n, const double *z,
             const armpl_int_t *ldz, double *rhs, double *rdsum,
             double *rdscal, const armpl_int_t *ipiv,
             const armpl_int_t *jpiv);
```

Parameters

IJOB Input parameter.

IJOB is INTEGER

IJOB = 2: First compute an approximative null-vector e of Z using DGECON, e is normalized and solve for Zx = +-e - f with the sign giving the greater value of 2-norm(x). About 5 times as expensive as Default. IJOB .ne. 2: Local look ahead strategy where all entries of the r.h.s. b is chosen as either +1 or -1 (Default).

N Input parameter.

N is INTEGER

The number of columns of the matrix Z.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). On entry, the LU part of the factorization of the n-by-n matrix Z computed by DGETC2: Z = P * L * U * Q

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDA >= max(1, N).

RHS Input and output parameter.

RHS is DOUBLE PRECISION

RHS is an array, dimension (N). On entry, RHS contains contributions from other subsystems. On exit, RHS contains the solution of the subsystem with entries acoording to the value of IJOB (see above).

RDSUM Input and output parameter.

RDSUM is DOUBLE PRECISION

On entry, the sum of squares of computed contributions to the Dif-estimate under computation by DTGSYL, where the scaling factor RDSCAL (see below) has been factored out. On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If TRANS = 'T' RDSUM is not touched. NOTE: RDSUM only makes sense when DTGSY2 is called by STGSYL.

RDSCAL Input and output parameter.

RDSCAL is DOUBLE PRECISION

On entry, scaling factor used to prevent overflow in RDSUM. On exit, RDSCAL is updated w.r.t. the current contributions in RDSUM. If TRANS = 'T', RDSCAL is not touched. NOTE: RDSCAL only makes sense when DTGSY2 is called by DTGSYL.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Input parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

4.17.360 dlatps

dlatps solves one of the triangular systems

```
A *x = s*b  or  A**T*x = s*b
```

with scaling to prevent overflow, where A is an upper or lower triangular matrix stored in packed form. Here A^T denotes the transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine DTPSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlatps(UPLO, TRANS, DIAG, NORMIN, N, AP, X, SCALE, CNORM, INFO)
```

C specification:

```
#include "armpl.h"

void dlatps_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n, const double *ap,
             double *x, double *scale, double *cnorm, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^T * x = s*b (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

The scaling factor s for the triangular system A * x = s*b or A^T * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is DOUBLE PRECISION

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatps*, *slatps* and *zlatps*.

4.17.361 dlatrd

dlatrd reduces NB rows and columns of a real symmetric matrix A to symmetric tridiagonal form by an orthogonal similarity transformation Q^T * A * Q, and returns the matrices V and W which are needed to apply the transformation to the unreduced part of A.

If UPLO = 'U', dlatrd reduces the last NB rows and columns of a matrix, of which the upper triangle is supplied; if UPLO = 'L', dlatrd reduces the first NB rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by DSYTRD.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlatrd(UPLO, N, NB, A, LDA, E, TAU, W, LDW)
```

C specification:

```
#include "armpl.h"

void dlatrd_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             double *a, const armpl_int_t *lda, double *e, double *tau,
             double *w, const armpl_int_t *ldw, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A.

NB Input parameter.

NB is INTEGER

The number of rows and columns to be reduced.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit: if UPLO = 'U', the last NB columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of A; the elements above the diagonal with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the first NB columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of A; the elements below the diagonal with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= (1, N).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). If UPLO = 'U', E(n-nb:n-1) contains the superdiagonal elements of the last NB columns of the reduced matrix; if UPLO = 'L', E(1:nb) contains the subdiagonal elements of the first NB columns of the reduced matrix.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors, stored in TAU(n-nb:n-1) if UPLO = 'U', and in TAU(1:nb) if UPLO = 'L'. See Further Details.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (LDW, NB). The n-by-nb matrix W required to update the unreduced part of A.

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

Related Information

For this routine in other precisions, please see *clatrd*, *slatrd* and *zlatrd*.

4.17.362 dlatrs

`dlatrs` solves one of the triangular systems

```
A *x = s*b  or  A**T *x = s*b
```

with scaling to prevent overflow. Here A is an upper or lower triangular matrix, A^T denotes the transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine DTRSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlatrs(UPLO, TRANS, DIAG, NORMIN, N, A, LDA, X, SCALE, CNORM,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dlatrs_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, double *x, double *scale, double *cnorm,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^T * x = s*b (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max (1, N).

X Input and output parameter.

X is DOUBLE PRECISION

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

The scaling factor s for the triangular system A * x = s*b or A^T * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is DOUBLE PRECISION

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatrs*, *slatrs* and *zlatrs*.

4.17.363 dlatrz

dlatrz factors the M-by-(M+L) real upper trapezoidal matrix [A1 A2] = [A(1:M,1:M) A(1:M,N-L+1:N)] as (R 0) * Z, by means of orthogonal transformations. Z is an (M+L)-by-(M+L) orthogonal matrix and, R and A1 are M-by-M upper triangular matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlatrz(M, N, L, A, LDA, TAU, WORK)
```

C specification:

```
#include "armpl.h"

void dlatrz_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             double *a, const armpl_int_t *lda, double *tau, double *work);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder vectors. N-M >= L >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements N-L+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (M). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (M) .

Related Information

For this routine in other precisions, please see *clatrz*, *slatrz* and *zlatrz*.

4.17.364 dlatsqr

dlatsqr computes a blocked Tall-Skinny QR factorization of an M-by-N matrix A, where M >= N: A = Q * R .

Syntax

Fortran specification:

```
use armpl_library

subroutine dlatsqr(M, N, MB, NB, A, LDA, T, LDT, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dlatsqr_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *mb, const armpl_int_t *nb, double *a,
              const armpl_int_t *lda, double *t, const armpl_int_t *ldt,
              double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. M >= N >= 0.

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. MB > N.

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. N >= NB >= 1.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the N-by-N upper triangular matrix R; the elements below the diagonal represent Q by the columns of blocked V (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array,. dimension (LDT, N * Number_of_row_blocks) where Number_of_row_blocks = CEIL((M-N)/(MB-N)) The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details below.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

(workspace) DOUBLE PRECISION

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

The dimension of the array WORK. LWORK >= NB*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatsqr*, *slatsqr* and *zlatsqr*.

4.17.365 dlauu2

dlauu2 computes the product U * U^T or L^T * L, where the triangular factor U or L is stored in the upper or lower triangular part of the array A.

If UPLO = 'U' or 'u' then the upper triangle of the result is stored, overwriting the factor U in A. If UPLO = 'L' or 'l' then the lower triangle of the result is stored, overwriting the factor L in A.

This is the unblocked form of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlauu2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dlauu2_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the triangular factor stored in the array A is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the triangular factor U or L. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the triangular factor U or L. On exit, if UPLO = 'U', the upper triangle of A is overwritten with the upper triangle of the product U * U^T ; if UPLO = 'L', the lower triangle of A is overwritten with the lower triangle of the product L^T * L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clauu2*, *slauu2* and *zlauu2*.

4.17.366 dlauum

dlauum computes the product U * U^T or L^T * L, where the triangular factor U or L is stored in the upper or lower triangular part of the array A.

If UPLO = 'U' or 'u' then the upper triangle of the result is stored, overwriting the factor U in A. If UPLO = 'L' or 'l' then the lower triangle of the result is stored, overwriting the factor L in A.

This is the blocked form of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlauum(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dlauum_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the triangular factor stored in the array A is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the triangular factor U or L. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the triangular factor U or L. On exit, if UPLO = 'U', the upper triangle of A is overwritten with the upper triangle of the product U * U^T ; if UPLO = 'L', the lower triangle of A is overwritten with the lower triangle of the product L^T * L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clauum*, *slauum* and *zlauum*. It also exists with a native C interface as *LAPACKE_dlauum*.

4.17.367 dorbdb1

dorbdb1 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                        [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                        [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. Q must be no larger than P, M-P, or M-Q. Routines DORBDB2, DORBDB3, and DORBDB4 handle cases in which Q is not the minimum dimension.

The orthogonal matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are Q-by-Q bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorbdb1(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorbdb1_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, double *x11, const armpl_int_t *ldx11,
              double *x21, const armpl_int_t *ldx21, double *theta,
              double *phi, double *taup1, double *taup2, double *tauq1,
              double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= MIN(P,M-P,M-Q).

X11 Input and output parameter.

X11 is DOUBLE PRECISION

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is DOUBLE PRECISION

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is DOUBLE PRECISION

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is DOUBLE PRECISION

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is DOUBLE PRECISION

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *sorbdb1*.

4.17.368 dorbdb2

dorbdb2 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                        [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                        [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. P must be no larger than M-P, Q, or M-Q. Routines DORBDB1, DORBDB3, and DORBDB4 handle cases in which P is not the minimum dimension.

The orthogonal matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are P-by-P bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorbdb2(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorbdb2_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, double *x11, const armpl_int_t *ldx11,
              double *x21, const armpl_int_t *ldx21, double *theta,
              double *phi, double *taup1, double *taup2, double *tauq1,
              double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= min(M-P, Q,M-Q).

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is DOUBLE PRECISION

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is DOUBLE PRECISION

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is DOUBLE PRECISION

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is DOUBLE PRECISION

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is DOUBLE PRECISION

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *sorbdb2*.

4.17.369 dorbdb3

dorbdb3 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                        [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                        [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. M-P must be no larger than P, Q, or M-Q. Routines DORBDB1, DORBDB2, and DORBDB4 handle cases in which M-P is not the minimum dimension.

The orthogonal matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are (M-P)-by-(M-P) bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorbdb3(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorbdb3_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, double *x11, const armpl_int_t *ldx11,
              double *x21, const armpl_int_t *ldx21, double *theta,
              double *phi, double *taup1, double *taup2, double *tauq1,
              double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M. M-P <= min(P, Q,M-Q).

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is DOUBLE PRECISION

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is DOUBLE PRECISION

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is DOUBLE PRECISION

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is DOUBLE PRECISION

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is DOUBLE PRECISION

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *sorbdb3*.

4.17.370 dorbdb4

dorbdb4 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                         [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                         [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. M-Q must be no larger than P, M-P, or Q. Routines DORBDB1, DORBDB2, and DORBDB3 handle cases in which M-Q is not the minimum dimension.

The orthogonal matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are (M-Q)-by-(M-Q) bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorbdb4(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, PHANTOM, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorbdb4_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, double *x11, const armpl_int_t *ldx11,
              double *x21, const armpl_int_t *ldx21, double *theta,
              double *phi, double *taup1, double *taup2, double *tauq1,
              double *phantom, double *work, const armpl_int_t *lwork,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M and M-Q <= min(P,M-P, Q).

X11 Input and output parameter.

X11 is DOUBLE PRECISION

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is DOUBLE PRECISION

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is DOUBLE PRECISION

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is DOUBLE PRECISION

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is DOUBLE PRECISION

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

PHANTOM Output parameter.

PHANTOM is DOUBLE PRECISION

PHANTOM is an array, dimension (M). The routine computes an M-by-1 column vector Y that is orthogonal to the columns of [X11; X21]. PHANTOM(1:P) and PHANTOM(P+1:M) contain Householder vectors for Y(1:P) and Y(P+1:M), respectively.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *sorbdb4*.

4.17.371 dorbdb5

`dorbdb5` orthogonalizes the column vector

```
X = [ X1 ]
    [ X2 ]
```

with respect to the columns of

```
Q = [ Q1 ] .
    [ Q2 ]
```

The columns of Q must be orthonormal.

If the projection is zero according to Kahan's "twice is enough" criterion, then some other vector from the orthogonal complement is returned. This vector is chosen in an arbitrary but deterministic way.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorbdb5(M1, M2, N, X1, INCX1, X2, INCX2, Q1, LDQ1, Q2, LDQ2, WORK,
                   LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorbdb5_(const armpl_int_t *m1, const armpl_int_t *m2,
              const armpl_int_t *n, double *x1, const armpl_int_t *incx1,
              double *x2, const armpl_int_t *incx2, double *q1,
              const armpl_int_t *ldq1, double *q2, const armpl_int_t *ldq2,
              double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M1 Input parameter.

`M1` is `INTEGER`

The dimension of `X1` and the number of rows in `Q1`. 0 <= `M1`.

M2 Input parameter.

`M2` is `INTEGER`

The dimension of `X2` and the number of rows in `Q2`. 0 <= `M2`.

N Input parameter.

`N` is `INTEGER`

The number of columns in `Q1` and `Q2`. 0 <= `N`.

X1 Input and output parameter.

`X1` is `DOUBLE PRECISION`

`X1` is an array, dimension (`M1`). On entry, the top part of the vector to be orthogonalized. On exit, the top part of the projected vector.

INCX1 Input parameter.

INCX1 is INTEGER

Increment for entries of X1.

X2 Input and output parameter.

X2 is DOUBLE PRECISION

X2 is an array, dimension (M2). On entry, the bottom part of the vector to be orthogonalized. On exit, the bottom part of the projected vector.

INCX2 Input parameter.

INCX2 is INTEGER

Increment for entries of X2.

Q1 Input parameter.

Q1 is DOUBLE PRECISION

Q1 is an array, dimension (LDQ1, N). The top part of the orthonormal basis matrix.

LDQ1 Input parameter.

LDQ1 is INTEGER

The leading dimension of Q1. LDQ1 >= M1.

Q2 Input parameter.

Q2 is DOUBLE PRECISION

Q2 is an array, dimension (LDQ2, N). The bottom part of the orthonormal basis matrix.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of Q2. LDQ2 >= M2.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *sorbdb5*.

4.17.372 dorbdb6

dorbdb6 orthogonalizes the column vector

```
X = [ X1 ]
    [ X2 ]
```

with respect to the columns of

```
Q = [ Q1 ] .
    [ Q2 ]
```

The columns of Q must be orthonormal.

If the projection is zero according to Kahan's "twice is enough" criterion, then the zero vector is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorbdb6(M1, M2, N, X1, INCX1, X2, INCX2, Q1, LDQ1, Q2, LDQ2, WORK,
                   LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorbdb6_(const armpl_int_t *m1, const armpl_int_t *m2,
              const armpl_int_t *n, double *x1, const armpl_int_t *incx1,
              double *x2, const armpl_int_t *incx2, double *q1,
              const armpl_int_t *ldq1, double *q2, const armpl_int_t *ldq2,
              double *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M1 Input parameter.

M1 is INTEGER

The dimension of X1 and the number of rows in Q1. 0 <= M1.

M2 Input parameter.

M2 is INTEGER

The dimension of X2 and the number of rows in Q2. 0 <= M2.

N Input parameter.

N is INTEGER

The number of columns in Q1 and Q2. 0 <= N.

X1 Input and output parameter.

X1 is DOUBLE PRECISION

X1 is an array, dimension (M1). On entry, the top part of the vector to be orthogonalized. On exit, the top part of the projected vector.

INCX1 Input parameter.

INCX1 is INTEGER

Increment for entries of X1.

X2 Input and output parameter.

X2 is DOUBLE PRECISION

X2 is an array, dimension (M2). On entry, the bottom part of the vector to be orthogonalized. On exit, the bottom part of the projected vector.

INCX2 Input parameter.

INCX2 is INTEGER

Increment for entries of X2.

Q1 Input parameter.

Q1 is DOUBLE PRECISION

Q1 is an array, dimension (LDQ1, N). The top part of the orthonormal basis matrix.

LDQ1 Input parameter.

LDQ1 is INTEGER

The leading dimension of Q1. LDQ1 >= M1.

Q2 Input parameter.

Q2 is DOUBLE PRECISION

Q2 is an array, dimension (LDQ2, N). The bottom part of the orthonormal basis matrix.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of Q2. LDQ2 >= M2.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *sorbdb6*.

4.17.373 dorg2l

dorg2l generates an m by n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by DGEQLF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorg2l(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorg2l_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             double *a, const armpl_int_t *lda, const double *tau,
             double *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGEQLF in the last k columns of its array argument A. On exit, the m by n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEQLF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *sorg2l*.

4.17.374 dorg2r

dorg2r generates an m by n real matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by DGEQRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorg2r(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorg2r_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             double *a, const armpl_int_t *lda, const double *tau,
             double *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGEQRF in the first k columns of its array argument A. On exit, the m-by-n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEQRF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *sorg2r*.

4.17.375 dorgl2

dorgl2 generates an m by n real matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by DGELQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorgl2(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorgl2_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             double *a, const armpl_int_t *lda, const double *tau,
             double *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by DGELQF in the first k rows of its array argument A. On exit, the m-by-n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGELQF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *sorgl2*.

4.17.376 dorgr2

dorgr2 generates an m by n real matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by DGERQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorgr2(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorgr2_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             double *a, const armpl_int_t *lda, const double *tau,
             double *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGERQF in the last k rows of its array argument A. On exit, the m by n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGERQF.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *sorgr2*.

4.17.377 dorm2l

dorm2l overwrites the general real m by n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**T * C  if SIDE = 'L' and TRANS = 'T', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**T if SIDE = 'R' and TRANS = 'T',
```

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by DGEQLF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorm2l(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorm2l_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left = 'R': apply Q or Q^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'T': apply Q^T (Transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGEQLF in the last k columns of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEQLF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sorm2l*.

4.17.378 dorm2r

dorm2r overwrites the general real m by n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**T* C  if SIDE = 'L' and TRANS = 'T', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**T if SIDE = 'R' and TRANS = 'T',
```

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by DGEQRF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorm2r(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorm2r_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left = 'R': apply Q or Q^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'T': apply Q^T (Transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGEQRF in the first k columns of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEQRF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sorm2r*.

4.17.379 dorml2

dorml2 overwrites the general real m by n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**T* C  if SIDE = 'L' and TRANS = 'T', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**T if SIDE = 'R' and TRANS = 'T',
```

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by DGELQF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dorml2(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorml2_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left = 'R': apply Q or Q^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'T': apply Q^T (Transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGELQF in the first k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGELQF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sorml2*.

4.17.380 dormr2

dormr2 overwrites the general real m by n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**T* C  if SIDE = 'L' and TRANS = 'T', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**T if SIDE = 'R' and TRANS = 'T',
```

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by DGERQF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dormr2(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dormr2_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const double *a,
             const armpl_int_t *lda, const double *tau, double *c,
             const armpl_int_t *ldc, double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left = 'R': apply Q or Q^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'T': apply Q' (Transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DGERQF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGERQF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormr2*.

4.17.381 dormr3

dormr3 overwrites the general real m by n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**T* C  if SIDE = 'L' and TRANS = 'C', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**T if SIDE = 'R' and TRANS = 'C',
```

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by DTZRZF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine dormr3(SIDE, TRANS, M, N, K, L, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dormr3_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const armpl_int_t *l,
             const double *a, const armpl_int_t *lda, const double *tau,
             double *c, const armpl_int_t *ldc, double *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left = 'R': apply Q or Q^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'T': apply Q^T (Transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by DTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DTZRZF.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormr3*.

4.17.382 dpbtf2

dpbtf2 computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

```
A = U**T * U ,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix, U^T is the transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpbtf2(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void dpbtf2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             double *ab, const armpl_int_t *ldab, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpbtf2*, *spbtf2* and *zpbtf2*.

4.17.383 dpotf2

dpotf2 computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

```
A = U**T * U ,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpotf2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dpotf2_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpotf2*, *spotf2* and *zpotf2*.

4.17.384 dpstf2

dpstf2 computes the Cholesky factorization with complete pivoting of a real symmetric positive semidefinite matrix A.

The factorization has the form

```
P**T * A * P = U**T * U ,  if UPLO = 'U',
P**T * A * P = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector PIV.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpstf2(UPLO, N, A, LDA, PIV, RANK, TOL, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dpstf2_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *piv, armpl_int_t *rank,
             const double *tol, double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization as above.

PIV Output parameter.

PIV is INTEGER array, dimension (N)

PIV is such that the nonzero entries are P(PIV(K), K) = 1.

RANK Output parameter.

RANK is INTEGER

The rank of A given by the number of steps the algorithm completed.

TOL Input parameter.

TOL is DOUBLE PRECISION

User defined tolerance. If TOL < 0, then N*U*MAX(A(K,K)) will be used. The algorithm terminates at the (K-1)st step if the pivot <= TOL.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N). Work space.

INFO Output parameter.

INFO is INTEGER

< 0: If INFO = -K, the K-th argument had an illegal value, = 0: algorithm completed successfully, and > 0: the matrix A is either rank deficient with computed rank as returned in RANK, or is not positive semidefinite. See Section 7 of LAPACK Working Note #161 for further information.

Related Information

For this routine in other precisions, please see *cpstf2*, *spstf2* and *zpstf2*.

4.17.385 dptts2

dptts2 solves a tridiagonal system of the form

```
A * X = B
```

using the L*D*L^T factorization of A computed by DPTTRF. D is a diagonal matrix specified in the vector D, L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E, and X and B are N by NRHS matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine dptts2(N, NRHS, D, E, B, LDB)
```

C specification:

```
#include "armpl.h"

void dptts2_(const armpl_int_t *n, const armpl_int_t *nrhs, const double *d,
             const double *e, double *b, const armpl_int_t *ldb);
```

Parameters

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the L*D*L^T factorization of A.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization A = U^T *D*U.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Related Information

For this routine in other precisions, please see *cptts2*, *sptts2* and *zptts2*.

4.17.386 drscl

drscl multiplies an n-element real vector x by the real scalar 1/a. This is done without overflow or underflow as long as the final result x/a does not overflow or underflow.

Syntax

Fortran specification:

```
use armpl_library

subroutine drscl(N, SA, SX, INCX)
```

C specification:

```
#include "armpl.h"

void drscl_(const armpl_int_t *n, const double *sa, double *sx,
            const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of components of the vector x.

SA Input parameter.

SA is DOUBLE PRECISION

The scalar a which is used to divide each component of x. SA must be >= 0, or the subroutine will divide by zero.

SX Input and output parameter.

SX is DOUBLE PRECISION

SX is an array, dimension. (1+(N-1)*abs(INCX)) The n-element vector x.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of the vector SX. > 0: SX(1) = X(1) and SX(1+(i-1)*INCX) = x(i), 1< i<= n

Related Information

For this routine in other precisions, please see *srscl*.

4.17.387 dsfrk

Level 3 BLAS like routine for C in RFP Format.

dsfrk performs one of the symmetric rank–k operations

```
C := alpha*A*A**T + beta*C,
```

or

```
C := alpha*A**T*A + beta*C,
```

where alpha and beta are real scalars, C is an n–by–n symmetric matrix and A is an n–by–k matrix in the first case and a k–by–n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsfrk(TRANSR, UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C)
```

C specification:

```
#include "armpl.h"

void dsfrk_(const char *transr, const char *uplo, const char *trans,
            const armpl_int_t *n, const armpl_int_t *k, const double *alpha,
            const double *a, const armpl_int_t *lda, const double *beta,
            double *c, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal Form of RFP A is stored; = 'T': The Transpose Form of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*A^T + beta*C.

TRANS = 'T' or 't' C := alpha*A^T * A + beta*C.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA,ka). where KA is K when TRANS = 'N' or 'n', and is N otherwise. Before entry with TRANS = 'N' or 'n', the leading N–by–K part of the array A must contain the matrix A, otherwise the leading K–by–N part of the array A must contain the matrix A. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION

On entry, BETA specifies the scalar beta. Unchanged on exit.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (NT). NT = N*(N+1)/2. On entry, the symmetric matrix C in RFP Format. RFP Format is described by TRANSR, UPLO and N.

Related Information

For this routine in other precisions, please see *ssfrk*. It also exists with a native C interface as *LAPACKE_dsfrk*.

4.17.388 dsyconv

dsyconv convert A given by TRF into L and D and vice-versa. Get Non-diag elements of D (returned in workspace) and apply or reverse permutation done in TRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyconv(UPLO, WAY, N, A, LDA, IPIV, E, INFO)
```

C specification:

```
#include "armpl.h"

void dsyconv_(const char *uplo, const char *way, const armpl_int_t *n,
              double *a, const armpl_int_t *lda, const armpl_int_t *ipiv,
              double *e, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). E stores the supdiagonal/subdiagonal of the symmetric 1-by-1 or 2-by-2 block diagonal matrix D in LDLT.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyconv*, *ssyconv* and *zsyconv*. It also exists with a native C interface as *LAPACKE_dsyconv*.

4.17.389 dsygs2

dsygs2 reduces a real symmetric-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^T or L^T*A*L.

B must have been previously factorized as U^T*U or L*L^T by DPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsygs2(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dsygs2_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             double *a, const armpl_int_t *lda, const double *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

= 1: compute inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T); = 2 or 3: compute U*A*U^T or L^T*A*L.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored, and how B has been factorized. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). The triangular factor from the Cholesky factorization of B, as returned by DPOTRF.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *ssygs2*.

4.17.390 dsyswapr

DSYSWAPR applies an elementary permutation on the rows and the columns of a symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyswapr(UPLO, N, A, LDA, I1, I2)
```

C specification:

```
#include "armpl.h"

void dsyswapr_(const char *uplo, const armpl_int_t *n, double *a,
               const armpl_int_t *lda, const armpl_int_t *i1,
               const armpl_int_t *i2, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

I1 Input parameter.

I1 is INTEGER

Index of the first row to swap

I2 Input parameter.

I2 is INTEGER

Index of the second row to swap

Related Information

For this routine in other precisions, please see *csyswapr*, *ssyswapr* and *zsyswapr*. It also exists with a native C interface as *LAPACKE_dsyswapr*.

4.17.391 dsytd2

`dsytd2` reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^T * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytd2(UPLO, N, A, LDA, D, E, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void dsytd2_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *d, double *e, double *tau,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *ssytd2*.

4.17.392 dsytf2

dsytf2 computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^T is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytf2(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dsytf2_(const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csytf2*, *ssytf2* and *zsytf2*.

4.17.393 dsytf2_rook

DSYTF2_ROOK computes the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^T is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytf2_rook(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dsytf2_rook_(const char *uplo, const armpl_int_t *n, double *a,
                  const armpl_int_t *lda, armpl_int_t *ipiv,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csytf2_rook*, *ssytf2_rook* and *zsytf2_rook*.

4.17.394 dtfsm

Level 3 BLAS like routine for A in RFP Format.

dtfsm solves the matrix equation

```
op( A )*X = alpha*B  or  X*op( A ) = alpha*B
```

where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T.
```

A is in Rectangular Full Packed (RFP) Format.

The matrix X is overwritten on B.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtfsm(TRANSR, SIDE, UPLO, TRANS, DIAG, M, N, ALPHA, A, B, LDB)
```

C specification:

```
#include "armpl.h"

void dtfsm_(const char *transr, const char *side, const char *uplo,
            const char *trans, const char *diag, const armpl_int_t *m,
            const armpl_int_t *n, const double *alpha, const double *a,
            double *b, const armpl_int_t *ldb, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal Form of RFP A is stored; = 'T': The Transpose Form of RFP A is stored.

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l' op(A)*X = alpha*B.

SIDE = 'R' or 'r' X*op(A) = alpha*B.

Unchanged on exit.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the RFP matrix A came from an upper or lower triangular matrix as follows: UPLO = 'U' or 'u' RFP A came from an upper triangular matrix UPLO = 'L' or 'l' RFP A came from a lower triangular matrix

Unchanged on exit.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANS = 'N' or 'n' op(A) = A.

TRANS = 'T' or 't' op(A) = A'.

Unchanged on exit.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not RFP A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (NT). NT = N*(N+1)/2. On entry, the matrix A in RFP Format. RFP Format is described by TRANSR, UPLO and N as follows: If TRANSR='N' then RFP A is (0:N,0:K-1) when N is even; K=N/2. RFP A is (0:N-1,0:K) when N is odd; K=N/2. If TRANSR = 'T' then RFP is the transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the NT elements of upper packed A either in normal or transpose Format. If UPLO = 'L' the RFP A contains the NT elements of lower packed A either in normal or transpose Format. The LDA of RFP

A is (N+1)/2 when TRANSR = 'T'. When TRANSR is 'N' the LDA is N+1 when N is even and is N when is odd. See the Note below for more details. Unchanged on exit.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m). Unchanged on exit.

Related Information

For this routine in other precisions, please see *ctfsm*, *stfsm* and *ztfsm*. It also exists with a native C interface as *LAPACKE_dtfsm*.

4.17.395 dtfttp

dtfttp copies a triangular matrix A from rectangular full packed format (TF) to standard packed format (TP).

Syntax

Fortran specification:

```
use armpl_library

subroutine dtfttp(TRANSR, UPLO, N, ARF, AP, INFO)
```

C specification:

```
#include "armpl.h"

void dtfttp_(const char *transr, const char *uplo, const armpl_int_t *n,
             const double *arf, double *ap, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF is in Normal format; = 'T': ARF is in Transpose format;

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ARF Input parameter.

ARF is DOUBLE PRECISION

ARF is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

AP Output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctfttp*, *stfttp* and *ztfttp*. It also exists with a native C interface as *LAPACKE_dtfttp*.

4.17.396 dtfttr

dtfttr copies a triangular matrix A from rectangular full packed format (TF) to standard full format (TR).

Syntax

Fortran specification:

```
use armpl_library

subroutine dtfttr(TRANSR, UPLO, N, ARF, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dtfttr_(const char *transr, const char *uplo, const armpl_int_t *n,
             const double *arf, double *a, const armpl_int_t *lda,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF is in Normal format; = 'T': ARF is in Transpose format.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrices ARF and A. N >= 0.

ARF Input parameter.

ARF is DOUBLE PRECISION

ARF is an array, dimension (N*(N+1)/2).. On entry, the upper (if UPLO = 'U') or lower (if UPLO = 'L') matrix A in RFP format. See the "Notes" below for more details.

A Output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctfttr*, *stfttr* and *ztfttr*. It also exists with a native C interface as *LAPACKE_dtfttr*.

4.17.397 dtgex2

dtgex2 swaps adjacent diagonal blocks (A11, B11) and (A22, B22) of size 1-by-1 or 2-by-2 in an upper (quasi) triangular matrix pair (A, B) by an orthogonal equivalence transformation.

(A, B) must be in generalized real Schur canonical form (as returned by DGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)**T = Q(out) * A(out) * Z(out)**T
Q(in) * B(in) * Z(in)**T = Q(out) * B(out) * Z(out)**T
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dtgex2(WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, J1, N1, N2,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtgex2_(const armpl_int_t *wantq, const armpl_int_t *wantz,
             const armpl_int_t *n, double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, double *q,
             const armpl_int_t *ldq, double *z, const armpl_int_t *ldz,
             const armpl_int_t *j1, const armpl_int_t *n1,
             const armpl_int_t *n2, double *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimensions (LDA, N). On entry, the matrix A in the pair (A, B). On exit, the updated matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimensions (LDB, N). On entry, the matrix B in the pair (A, B). On exit, the updated matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. Not referenced if WANTQ = .FALSE..

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). On entry, if WANTZ =.TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. Not referenced if WANTZ = .FALSE..

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

J1 Input parameter.

J1 is INTEGER

The index to the first block (A11, B11). 1 <= J1 <= N.

N1 Input parameter.

N1 is INTEGER

The order of the first block (A11, B11). N1 = 0, 1 or 2.

N2 Input parameter.

N2 is INTEGER

The order of the second block (A22, B22). N2 = 0, 1 or 2.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(1, N*(N2+N1), (N2+N1)*(N2+N1)*2)

INFO Output parameter.

INFO is INTEGER

=0: Successful exit >0: If INFO = 1, the transformed matrix (A, B) would be too far from generalized Schur form; the blocks are not swapped and (A, B) and (Q, Z) are unchanged. The problem of swapping is too ill-conditioned. <0: If INFO = -16: LWORK is too small. Appropriate value for LWORK is returned in WORK(1).

Related Information

4.17.398 dtgsy2

dtgsy2 solves the generalized Sylvester equation:

```
A * R - L * B = scale * C                (1)
D * R - L * E = scale * F,
```

using Level 1 and 2 BLAS. where R and L are unknown M-by-N matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size M-by-M, N-by-N and M-by-N, respectively, with real entries. (A, D) and (B, E) must be in generalized Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular. The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation solving equation (1) corresponds to solve Z*x = scale*b, where Z is defined as

```
Z = [ kron(In, A)  -kron(B**T, Im) ]             (2)
    [ kron(In, D)  -kron(E**T, Im) ],
```

Ik is the identity matrix of size k and X^T is the transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y. In the process of solving (1), we solve a number of such systems where Dim(In), Dim(In) = 1 or 2.

If TRANS = 'T', solve the transposed system Z^T *y = scale*b for y, which is equivalent to solve for R and L in

```
A**T * R  + D**T * L   = scale * C           (3)
R  * B**T + L  * E**T  = scale * -F
```

This case is used to compute an estimate of Dif[(A, D), (B, E)] = sigma_min(Z) using reverse communicaton with DLACON.

dtgsy2 also (IJOB >= 1) contributes to the computation in DTGSYL of an upper bound on the separation between to matrix pairs. Then the input (A, D), (B, E) are sub-pencils of the matrix pair in DTGSYL. See DTGSYL for details.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtgsy2(TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD, E, LDE,
                  F, LDF, SCALE, RDSUM, RDSCAL, IWORK, PQ, INFO)
```

C specification:

```
#include "armpl.h"

void dtgsy2_(const char *trans, const armpl_int_t *ijob, const armpl_int_t *m,
             const armpl_int_t *n, const double *a, const armpl_int_t *lda,
             const double *b, const armpl_int_t *ldb, double *c,
             const armpl_int_t *ldc, const double *d, const armpl_int_t *ldd,
             const double *e, const armpl_int_t *lde, double *f,
             const armpl_int_t *ldf, double *scale, double *rdsum,
             double *rdscal, armpl_int_t *iwork, armpl_int_t *pq,
             armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N', solve the generalized Sylvester equation (1). = 'T': solve the 'transposed' system (3).

IJOB Input parameter.

IJOB is INTEGER

Specifies what kind of functionality to be performed. = 0: solve (1) only. = 1: A contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed. (look ahead strategy is used). = 2: A contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed. (DGECON on sub-systems is used.) Not referenced if TRANS = 'T'.

M Input parameter.

M is INTEGER

On entry, M specifies the order of A and D, and the row dimension of C, F, R and L.

N Input parameter.

N is INTEGER

On entry, N specifies the order of B and E, and the column dimension of C, F, R and L.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, M). On entry, A contains an upper quasi triangular matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the matrix A. LDA >= max(1, M).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, B contains an upper quasi triangular matrix.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the matrix B. LDB >= max(1, N).

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, C contains the right-hand-side of the first matrix equation in (1). On exit, if IJOB = 0, C has been overwritten by the solution R.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the matrix C. LDC >= max(1, M).

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (LDD, M). On entry, D contains an upper triangular matrix.

LDD Input parameter.

LDD is INTEGER

The leading dimension of the matrix D. LDD >= max(1, M).

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (LDE, N). On entry, E contains an upper triangular matrix.

LDE Input parameter.

LDE is INTEGER

The leading dimension of the matrix E. LDE >= max(1, N).

F Input and output parameter.

F is DOUBLE PRECISION

F is an array, dimension (LDF, N). On entry, F contains the right-hand-side of the second matrix equation in (1). On exit, if IJOB = 0, F has been overwritten by the solution L.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the matrix F. LDF >= max(1, M).

SCALE Output parameter.

SCALE is DOUBLE PRECISION

On exit, 0 <= SCALE <= 1. If 0 < SCALE < 1, the solutions R and L (C and F on entry) will hold the solutions to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If SCALE = 0, R and L will hold the solutions to the homogeneous system with C = F = 0. Normally, SCALE = 1.

RDSUM Input and output parameter.

RDSUM is DOUBLE PRECISION

On entry, the sum of squares of computed contributions to the Dif-estimate under computation by DTGSYL, where the scaling factor RDSCAL (see below) has been factored out. On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If TRANS = 'T' RDSUM is not touched. NOTE: RDSUM only makes sense when DTGSY2 is called by DTGSYL.

RDSCAL Input and output parameter.

RDSCAL is DOUBLE PRECISION

On entry, scaling factor used to prevent overflow in RDSUM. On exit, RDSCAL is updated w.r.t. the current contributions in RDSUM. If TRANS = 'T', RDSCAL is not touched. NOTE: RDSCAL only makes sense when DTGSY2 is called by DTGSYL.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M+N+2)

PQ Output parameter.

PQ is INTEGER

On exit, the number of subsystems (of size 2-by-2, 4-by-4 and 8-by-8) solved by this routine.

INFO Output parameter.

INFO is INTEGER

On exit, if INFO is set to =0: Successful exit <0: If INFO = -i, the i-th argument had an illegal value. >0: The matrix pairs (A, D) and (B, E) have common or very close eigenvalues.

Related Information

4.17.399 dtplqt2

dtplqt2 computes a LQ a factorization of a real "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtplqt2(M, N, L, A, LDA, B, LDB, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void dtplqt2_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *l, double *a, const armpl_int_t *lda,
              double *b, const armpl_int_t *ldb, double *t,
              const armpl_int_t *ldt, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The total number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the lower trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, M). On entry, the lower triangular M-by-M matrix A. On exit, the elements on and below the diagonal of the array contain the lower triangular matrix L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first N-L columns are rectangular, and the last L columns are lower trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, M). The N-by-N upper triangular factor T of the block reflector. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, M)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctplqt2*, *stplqt2* and *ztplqt2*.

4.17.400 dtpqrt2

dtpqrt2 computes a QR factorization of a real "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtpqrt2(M, N, L, A, LDA, B, LDB, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void dtpqrt2_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *l, double *a, const armpl_int_t *lda,
              double *b, const armpl_int_t *ldb, double *t,
              const armpl_int_t *ldt, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The total number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the upper trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the upper triangular N-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first M-L rows are rectangular, and the last L rows are upper trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). The N-by-N upper triangular factor T of the block reflector. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpqrt2*, *stpqrt2* and *ztpqrt2*. It also exists with a native C interface as *LAPACKE_dtpqrt2*.

4.17.401 dtprfb

dtprfb applies a real "triangular-pentagonal" block reflector H or its transpose H^T to a real matrix C, which is composed of two blocks A and B, either from the left or right.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtprfb(SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV, T, LDT, A,
                  LDA, B, LDB, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void dtprfb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l, const double *v,
             const armpl_int_t *ldv, const double *t, const armpl_int_t *ldt,
             double *a, const armpl_int_t *lda, double *b,
             const armpl_int_t *ldb, double *work, const armpl_int_t *ldwork,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^T from the Left = 'R': apply H or H^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'T': apply H^T (Transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columns = 'R': Rows

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The order of the matrix T, i.e. the number of elementary reflectors whose product defines the block reflector. K >= 0.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

V Input parameter.

V is DOUBLE PRECISION

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, M) if STOREV = 'R' and SIDE = 'L' (LDV, N) if STOREV = 'R' and SIDE = 'R' The pentagonal matrix V, which contains the elementary reflectors H(1), H(2), . . . , H(K). See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C' and SIDE = 'L', LDV >= max(1, M); if STOREV = 'C' and SIDE = 'R', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of H*C or H^T *C or C*H or C*H^T . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of H*C or H^T *C or C*H or C*H^T . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension. (LDWORK, N) if SIDE = 'L', (LDWORK, K) if SIDE = 'R'.

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= K; if SIDE = 'R', LDWORK >= M.

Related Information

For this routine in other precisions, please see *ctprfb*, *stprfb* and *ztprfb*. It also exists with a native C interface as *LAPACKE_dtprfb*.

4.17.402 dtpttf

dtpttf copies a triangular matrix A from standard packed format (TP) to rectangular full packed format (TF).

Syntax

Fortran specification:

```
use armpl_library

subroutine dtpttf(TRANSR, UPLO, N, AP, ARF, INFO)
```

C specification:

```
#include "armpl.h"

void dtpttf_(const char *transr, const char *uplo, const armpl_int_t *n,
             const double *ap, double *arf, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF in Normal format is wanted; = 'T': ARF in Conjugate-transpose format is wanted.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

ARF Output parameter.

ARF is DOUBLE PRECISION

ARF is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpttf*, *stpttf* and *ztpttf*. It also exists with a native C interface as *LAPACKE_dtpttf*.

4.17.403 dtpttr

dtpttr copies a triangular matrix A from standard packed format (TP) to standard full format (TR).

Syntax

Fortran specification:

```
use armpl_library

subroutine dtpttr(UPLO, N, AP, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dtpttr_(const char *uplo, const armpl_int_t *n, const double *ap,
             double *a, const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular. = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

A Output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpttr*, *stpttr* and *ztpttr*. It also exists with a native C interface as *LAPACKE_dtpttr*.

4.17.404 dtrti2

dtrti2 computes the inverse of a real upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrti2(UPLO, DIAG, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void dtrti2_(const char *uplo, const char *diag, const armpl_int_t *n,
             double *a, const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrti2*, *strti2* and *ztrti2*.

4.17.405 dtrttf

dtrttf copies a triangular matrix A from standard full format (TR) to rectangular full packed format (TF) .

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrttf(TRANSR, UPLO, N, A, LDA, ARF, INFO)
```

C specification:

```
#include "armpl.h"

void dtrttf_(const char *transr, const char *uplo, const armpl_int_t *n,
             const double *a, const armpl_int_t *lda, double *arf,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF in Normal form is wanted; = 'T': ARF in Transpose form is wanted.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N).. On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the matrix A. LDA >= max(1, N).

ARF Output parameter.

ARF is DOUBLE PRECISION

ARF is an array, dimension (NT).. NT=N*(N+1)/2. On exit, the triangular matrix A in RFP format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrttf*, *strttf* and *ztrttf*. It also exists with a native C interface as *LAPACKE_dtrttf*.

4.17.406 dtrttp

dtrttp copies a triangular matrix A from full format (TR) to standard packed format (TP).

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrttp(UPLO, N, A, LDA, AP, INFO)
```

C specification:

```
#include "armpl.h"

void dtrttp_(const char *uplo, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, double *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular. = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrices AP and A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AP Output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On exit, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrttp*, *strttp* and *ztrttp*. It also exists with a native C interface as *LAPACKE_dtrttp*.

4.17.407 dzsum1

`dzsum1` takes the sum of the absolute values of a complex vector and returns a double precision result.

Based on DZASUM from the Level 1 BLAS. The change is to use the 'genuine' absolute value.

Syntax

Fortran specification:

```
use armpl_library

double precision function dzsum1(N, CX, INCX)
```

C specification:

```
#include "armpl.h"

double dzsum1_(const armpl_int_t *n, const armpl_doublecomplex_t *cx,
               const armpl_int_t *incx);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The number of elements in the vector `CX`.

CX Input parameter.

`CX` is `COMPLEX*16`

`CX` is an array, dimension (`N`). The vector whose elements will be summed.

INCX Input parameter.

`INCX` is `INTEGER`

The spacing between successive values of `CX`. `INCX` > 0.

Related Information

4.17.408 scsum1

`scsum1` takes the sum of the absolute values of a complex vector and returns a single precision result.

Based on SCASUM from the Level 1 BLAS. The change is to use the 'genuine' absolute value.

Syntax

Fortran specification:

```
use armpl_library

real function scsum1(N, CX, INCX)
```

C specification:

```
#include "armpl.h"

float scsum1_(const armpl_int_t *n, const armpl_singlecomplex_t *cx,
              const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements in the vector CX.

CX Input parameter.

CX is COMPLEX

CX is an array, dimension (N). The vector whose elements will be summed.

INCX Input parameter.

INCX is INTEGER

The spacing between successive values of CX. INCX > 0.

Related Information

4.17.409 sgbtf2

sgbtf2 computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges. This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbtf2(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void sgbtf2_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku, float *ab,
             const armpl_int_t *ldab, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgbtf2*, *dgbtf2* and *zgbtf2*.

4.17.410 sgebd2

sgebd2 reduces a real general m by n matrix A to upper or lower bidiagonal form B by an orthogonal transformation: $Q^T * A * P = B$.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgebd2(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgebd2_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *d, float *e, float *tauq,
             float *taup, float *work, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns in the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the m by n general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is REAL

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (min(M, N)-1). The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ Output parameter.

TAUQ is REAL

TAUQ is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

TAUP Output parameter.

TAUP is REAL

TAUP is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (max(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebd2*, *dgebd2* and *zgebd2*.

4.17.411 sgehd2

sgehd2 reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: $Q^T * A * Q = H$.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgehd2(N, ILO, IHI, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgehd2_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, float *a, const armpl_int_t *lda,
             float *tau, float *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL; otherwise they should be set to 1 and N respectively. See Further Details. 1 <= ILO <= IHI <= max(1, N).

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the n by n general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgehd2*, *dgehd2* and *zgehd2*.

4.17.412 sgelq2

sgelq2 computes an LQ factorization of a real m by n matrix A: A = L * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgelq2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgelq2_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *tau, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and below the diagonal of the array contain the m by min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelq2*, *dgelq2* and *zgelq2*. It also exists with a native C interface as *LAPACKE_sgelq2*.

4.17.413 sgelqt3

DGELQT3 recursively computes a LQ factorization of a real M-by-N matrix A, using the compact WY representation of Q.
Based on the algorithm of Elmroth and Gustavson, IBM J. Res. Develop. Vol 44 No. 4 July 2000.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine sgelqt3(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void sgelqt3_(const armpl_int_t *m, const armpl_int_t *n, float *a,
              const armpl_int_t *lda, float *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M =< N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the real M-by-N matrix A. On exit, the elements on and below the diagonal contain the N-by-N lower triangular matrix L; the elements above the diagonal are the rows of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelqt3*, *dgelqt3* and *zgelqt3*.

4.17.414 sgeql2

sgeql2 computes a QL factorization of a real m by n matrix A: A = Q * L.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeql2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeql2_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *tau, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the n by n lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the m by n lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeql2*, *dgeql2* and *zgeql2*.

4.17.415 sgeqr2

sgeqr2 computes a QR factorization of a real m by n matrix A: A = Q * R.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeqr2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqr2_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *tau, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and above the diagonal of the array contain the min(m,n) by n upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqr2*, *dgeqr2* and *zgeqr2*. It also exists with a native C interface as *LAPACKE_sgeqr2*.

4.17.416 sgeqr2p

sgeqr2p computes a QR factorization of a real m by n matrix A: A = Q * R. The diagonal entries of R are nonnegative.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeqr2p(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqr2p_(const armpl_int_t *m, const armpl_int_t *n, float *a,
              const armpl_int_t *lda, float *tau, float *work,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and above the diagonal of the array contain the min(m,n) by n upper trapezoidal matrix R (R is upper triangular if m >= n). The diagonal entries of R are nonnegative; the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqr2p*, *dgeqr2p* and *zgeqr2p*.

4.17.417 sgeqrt2

`sgeqrt2` computes a QR factorization of a real M-by-N matrix A, using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeqrt2(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqrt2_(const armpl_int_t *m, const armpl_int_t *n, float *a,
              const armpl_int_t *lda, float *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= `N`.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `REAL`

`A` is an array, dimension (`LDA`, `N`). On entry, the real M-by-N matrix `A`. On exit, the elements on and above the diagonal contain the N-by-N upper triangular matrix R; the elements below the diagonal are the columns of V. See below for further details.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

T Output parameter.

`T` is `REAL`

`T` is an array, dimension (`LDT`, `N`). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

`LDT` is `INTEGER`

The leading dimension of the array `T`. `LDT` >= max(1, `N`).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrt2*, *dgeqrt2* and *zgeqrt2*. It also exists with a native C interface as *LAPACKE_sgeqrt2*.

4.17.418 sgeqrt3

sgeqrt3 recursively computes a QR factorization of a real M-by-N matrix A, using the compact WY representation of Q.

Based on the algorithm of Elmroth and Gustavson, IBM J. Res. Develop. Vol 44 No. 4 July 2000.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine sgeqrt3(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void sgeqrt3_(const armpl_int_t *m, const armpl_int_t *n, float *a,
              const armpl_int_t *lda, float *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the real M-by-N matrix A. On exit, the elements on and above the diagonal contain the N-by-N upper triangular matrix R; the elements below the diagonal are the columns of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrt3*, *dgeqrt3* and *zgeqrt3*. It also exists with a native C interface as *LAPACKE_sgeqrt3*.

4.17.419 sgerq2

sgerq2 computes an RQ factorization of a real m by n matrix A: A = R * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgerq2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgerq2_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *tau, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the m by m upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the m by n upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgerq2*, *dgerq2* and *zgerq2*.

4.17.420 sgesc2

sgesc2 solves a system of linear equations

```
A * X = scale* RHS
```

with a general N-by-N matrix A using the LU factorization with complete pivoting computed by SGETC2.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgesc2(N, A, LDA, RHS, IPIV, JPIV, SCALE)
```

C specification:

```
#include "armpl.h"

void sgesc2_(const armpl_int_t *n, const float *a, const armpl_int_t *lda,
             float *rhs, const armpl_int_t *ipiv, const armpl_int_t *jpiv,
             float *scale);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the LU part of the factorization of the n-by-n matrix A computed by SGETC2: A = P * L * U * Q

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

RHS Input and output parameter.

RHS is REAL

RHS is an array, dimension (N).. On entry, the right hand side vector b. On exit, the solution vector X.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Input parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

SCALE Output parameter.

SCALE is REAL

On exit, SCALE contains the scale factor. SCALE is chosen 0 <= SCALE <= 1 to prevent owerflow in the solution.

Related Information

For this routine in other precisions, please see *cgesc2*, *dgesc2* and *zgesc2*.

4.17.421 sgetc2

sgetc2 computes an LU factorization with complete pivoting of the n-by-n matrix A. The factorization has the form A = P * L * U * Q, where P and Q are permutation matrices, L is lower triangular with unit diagonal elements and U is upper triangular.

This is the Level 2 BLAS algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgetc2(N, A, LDA, IPIV, JPIV, INFO)
```

C specification:

```
#include "armpl.h"

void sgetc2_(const armpl_int_t *n, float *a, const armpl_int_t *lda,
             armpl_int_t *ipiv, armpl_int_t *jpiv, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the n-by-n matrix A to be factored. On exit, the factors L and U from the factorization A = P*L*U*Q; the unit diagonal elements of L are not stored. If U(k, k) appears to be less than SMIN, U(k, k) is given the value of SMIN, i.e., giving a nonsingular perturbed system.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension(N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Output parameter.

JPIV is INTEGER array, dimension(N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, U(k, k) is likely to produce owerflow if we try to solve for x in Ax = b. So U is perturbed to avoid the overflow.

Related Information

For this routine in other precisions, please see *cgetc2*, *dgetc2* and *zgetc2*.

4.17.422 sgetf2

sgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 2 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgetf2(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void sgetf2_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgetf2*, *dgetf2* and *zgetf2*. It also exists with a native C interface as *LAPACKE_sgetf2*.

4.17.423 sgsvj0

sgsvj0 is called from SGESVJ as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as SGESVJ does, but it does not check convergence (stopping criterion). Few tuning parameters (marked by [TP]) are available for the implementer.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgsvj0(JOBV, M, N, A, LDA, D, SVA, MV, V, LDV, EPS, SFMIN, TOL,
                  NSWEEP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgsvj0_(const char *jobv, const armpl_int_t *m, const armpl_int_t *n,
             float *a, const armpl_int_t *lda, float *d, float *sva,
             const armpl_int_t *mv, float *v, const armpl_int_t *ldv,
             const float *eps, const float *sfmin, const float *tol,
             const armpl_int_t *nsweep, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether the output from this procedure is used to compute the matrix V: = 'V': the product of the Jacobi rotations is accumulated by postmulyiplying the N-by-N array V. (See the description of V.) = 'A': the product of the Jacobi rotations is accumulated by postmulyiplying the MV-by-N array V. (See the descriptions of MV and V.) = 'N': the Jacobi rotations are not accumulated.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, M-by-N matrix A, such that A*diag(D) represents the input matrix. On exit, A_onexit * D_onexit represents the input matrix A*diag(D) post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of D, TOL and NSWEEP.)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Input and output parameter.

D is REAL

D is an array, dimension (N). The array D accumulates the scaling factors from the fast scaled Jacobi rotations. On entry, A*diag(D) represents the input matrix. On exit, A_onexit*diag(D_onexit) represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of A, TOL and NSWEEP.)

SVA Input and output parameter.

SVA is REAL

SVA is an array, dimension (N). On entry, SVA contains the Euclidean norms of the columns of the matrix A*diag(D). On exit, SVA contains the Euclidean norms of the columns of the matrix onexit*diag(D_onexit).

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then MV is not referenced.

V Input and output parameter.

V is REAL

V is an array, dimension (LDV, N). If JOBV .EQ. 'V' then N rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV .EQ. 'A' then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V', LDV .GE. N. If JOBV = 'A', LDV .GE. MV.

EPS Input parameter.

EPS is REAL

EPS = SLAMCH('Epsilon')

SFMIN Input parameter.

SFMIN is REAL

SFMIN = SLAMCH('Safe Minimum')

TOL Input parameter.

TOL is REAL

TOL is the threshold for Jacobi rotations. For a pair A(:,p), A(:,q) of pivot columns, the Jacobi rotation is applied only if ABS(COS(angle(A(:,p),A(:,q)))) .GT. TOL.

NSWEEP Input parameter.

NSWEEP is INTEGER

NSWEEP is the number of sweeps of Jacobi rotations to be performed.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

LWORK is the dimension of WORK. LWORK .GE. M.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgsvj0*, *dgsvj0* and *zgsvj0*.

4.17.424 sgsvj1

`sgsvj1` is called from SGESVJ as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as SGESVJ does, but it targets only particular pivots and it does not check convergence (stopping criterion). Few tunning parameters (marked by [TP]) are available for the implementer.

Further Details

`sgsvj1` applies few sweeps of Jacobi rotations in the column space of the input M-by-N matrix A. The pivot pairs are taken from the (1,2) off-diagonal block in the corresponding N-by-N Gram matrix A^T * A. The block-entries (tiles) of the (1,2) off-diagonal block are marked by the [x]'s in the following scheme:

```
| *  *  * [x] [x] [x]|
| *  *  * [x] [x] [x]|    Row-cycling in the nblr-by-nblc [x] blocks.
| *  *  * [x] [x] [x]|    Row-cyclic pivoting inside each [x] block.
|[x] [x] [x] *  *  * |
|[x] [x] [x] *  *  * |
|[x] [x] [x] *  *  * |
```

In terms of the columns of A, the first N1 columns are rotated 'against' the remaining N-N1 columns, trying to increase the angle between the corresponding subspaces. The off-diagonal block is N1-by(N-N1) and it is tiled using quadratic tiles of side KBL. Here, KBL is a tunning parmeter. The number of sweeps is given in NSWEEP and the orthogonality threshold is given in TOL.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgsvj1(JOBV, M, N, N1, A, LDA, D, SVA, MV, V, LDV, EPS, SFMIN, TOL,
                  NSWEEP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgsvj1_(const char *jobv, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *n1, float *a, const armpl_int_t *lda,
             float *d, float *sva, const armpl_int_t *mv, float *v,
             const armpl_int_t *ldv, const float *eps, const float *sfmin,
             const float *tol, const armpl_int_t *nsweep, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether the output from this procedure is used to compute the matrix V: = 'V': the product of the Jacobi rotations is accumulated by postmulyiplying the N-by-N array V. (See the description of V.) =

'A': the product of the Jacobi rotations is accumulated by postmulyiplying the MV-by-N array V. (See the descriptions of MV and V.) = 'N': the Jacobi rotations are not accumulated.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

N1 Input parameter.

N1 is INTEGER

N1 specifies the 2 x 2 block partition, the first N1 columns are rotated 'against' the remaining N-N1 columns of A.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, M-by-N matrix A, such that A*diag(D) represents the input matrix. On exit, A_onexit * D_onexit represents the input matrix A*diag(D) post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of N1, D, TOL and NSWEEP.)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Input and output parameter.

D is REAL

D is an array, dimension (N). The array D accumulates the scaling factors from the fast scaled Jacobi rotations. On entry, A*diag(D) represents the input matrix. On exit, A_onexit*diag(D_onexit) represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of N1, A, TOL and NSWEEP.)

SVA Input and output parameter.

SVA is REAL

SVA is an array, dimension (N). On entry, SVA contains the Euclidean norms of the columns of the matrix A*diag(D). On exit, SVA contains the Euclidean norms of the columns of the matrix onexit*diag(D_onexit).

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then MV is not referenced.

V Input and output parameter.

V is REAL

V is an array, dimension (LDV, N). If JOBV .EQ. 'V' then N rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV .EQ. 'A' then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V', LDV .GE. N. If JOBV = 'A', LDV .GE. MV.

EPS Input parameter.

EPS is REAL

EPS = SLAMCH('Epsilon')

SFMIN Input parameter.

SFMIN is REAL

SFMIN = SLAMCH('Safe Minimum')

TOL Input parameter.

TOL is REAL

TOL is the threshold for Jacobi rotations. For a pair A(:,p), A(:,q) of pivot columns, the Jacobi rotation is applied only if ABS(COS(angle(A(:,p),A(:,q)))) .GT. TOL.

NSWEEP Input parameter.

NSWEEP is INTEGER

NSWEEP is the number of sweeps of Jacobi rotations to be performed.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

LWORK is the dimension of WORK. LWORK .GE. M.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgsvj1*, *dgsvj1* and *zgsvj1*.

4.17.425 sgtts2

sgtts2 solves one of the systems of equations

```
A*X = B  or  A**T*X = B,
```

with a tridiagonal matrix A using the LU factorization computed by SGTTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgtts2(ITRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB)
```

C specification:

```
#include "armpl.h"

void sgtts2_(const armpl_int_t *itrans, const armpl_int_t *n,
             const armpl_int_t *nrhs, const float *dl, const float *d,
             const float *du, const float *du2, const armpl_int_t *ipiv,
             float *b, const armpl_int_t *ldb);
```

Parameters

ITRANS Input parameter.

ITRANS is INTEGER

Specifies the form of the system of equations. = 0: A * X = B (No transpose) = 1: A^T * X = B (Transpose) = 2: A^T * X = B (Conjugate transpose = Transpose)

N Input parameter.

N is INTEGER

The order of the matrix A.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is REAL

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is REAL

DU is an array, dimension (N-1). The (n-1) elements of the first super-diagonal of U.

DU2 Input parameter.

DU2 is REAL

DU2 is an array, dimension (N-2). The (n-2) elements of the second super-diagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Related Information

For this routine in other precisions, please see *cgtts2*, *dgtts2* and *zgtts2*.

4.17.426 sisnan

sisnan returns .TRUE. if its argument is NaN, and .FALSE. otherwise. To be replaced by the Fortran 2003 intrinsic in the future.

Syntax

Fortran specification:

```
use armpl_library

logical function sisnan(SIN)
```

C specification:

```
#include "armpl.h"

armpl_int_t sisnan_(const float *sin);
```

Parameters

SIN Input parameter.

SIN is REAL

Input to test for NaN.

Related Information

For this routine in other precisions, please see *disnan*.

4.17.427 sla_gbamv

SLA_GBAMV performs one of the matrix-vector operations

```
      y := alpha*abs(A)*abs(x) + beta*abs(y),
or    y := alpha*abs(A)**T*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, “symbolically” zero components are not perturbed. A zero entry is considered “symbolic” if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine sla_gbamv(TRANS, M, N, KL, KU, ALPHA, AB, LDAB, X, INCX, BETA, Y,
                     INCY)
```

C specification:

```
#include "armpl.h"

void sla_gbamv_(const armpl_int_t *trans, const armpl_int_t *m,
                const armpl_int_t *n, const armpl_int_t *kl,
                const armpl_int_t *ku, const float *alpha, const float *ab,
                const armpl_int_t *ldab, const float *x,
                const armpl_int_t *incx, const float *beta, float *y,
                const armpl_int_t *incy);
```

Parameters

TRANS Input parameter.

TRANS is INTEGER

On entry, TRANS specifies the operation to be performed as follows:

BLAS_NO_TRANS y := alpha*abs(A)*abs(x) + beta*abs(y) BLAS_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y) BLAS_CONJ_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y)

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, n). Before entry, the leading m by n part of the array AB must contain the matrix of coefficients. Unchanged on exit.

LDAB Input parameter.

LDAB is INTEGER

On entry, LDA specifies the first dimension of AB as declared in the calling (sub) program. LDAB must be at least max(1, m). Unchanged on exit.

X Input parameter.

X is REAL

X is an array, dimension. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is REAL

Y is an array, dimension. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Level 2 Blas routine.

Related Information

For this routine in other precisions, please see *cla_gbamv*, *dla_gbamv* and *zla_gbamv*.

4.17.428 sla_gbrcond

```
SLA_GBRCOND Estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number  cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.
```

Syntax

Fortran specification:

```
use armpl_library

real function sla_gbrcond(TRANS, N, KL, KU, AB, LDAB, AFB, LDAFB, IPIV, CMODE,
                          C, INFO, WORK, IWORK)
```

C specification:

```
#include "armpl.h"

float sla_gbrcond_(const char *trans, const armpl_int_t *n,
                   const armpl_int_t *kl, const armpl_int_t *ku,
                   const float *ab, const armpl_int_t *ldab, const float *afb,
                   const armpl_int_t *ldafb, const armpl_int_t *ipiv,
                   const armpl_int_t *cmode, const float *c,
                   armpl_int_t *info, float *work, armpl_int_t *iwork, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is REAL

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by SGBTRF; row i of the matrix was interchanged with row IPIV(i).

CMODE Input parameter.

CMODE is INTEGER

Determines op2(C) in the formula op(A) * op2(C) as follows: CMODE = 1 op2(C) = C CMODE = 0 op2(C) = I CMODE = -1 op2(C) = inv(C)

C Input parameter.

C is REAL

C is an array, dimension (N). The vector C in the formula op(A) * op2(C).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is REAL

WORK is an array, dimension (5*N).. Workspace.

IWORK Input parameter.

IWORK is INTEGER array, dimension (N).

Workspace.

Related Information

For this routine in other precisions, please see *dla_gbrcond*.

4.17.429 sla_gbrfsx_extended

sla_gbrfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by SGBRFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine sla_gbrfsx_extended(PREC_TYPE, TRANS_TYPE, N, KL, KU, NRHS, AB,
                               LDAB, AFB, LDAFB, IPIV, COLEQU, C, B, LDB, Y,
                               LDY, BERR_OUT, N_NORMS, ERR_BNDS_NORM,
                               ERR_BNDS_COMP, RES, AYB, DY, Y_TAIL, RCOND,
                               ITHRESH, RTHRESH, DZ_UB, IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void sla_gbrfsx_extended_(const armpl_int_t *prec_type,
                          const armpl_int_t *trans_type, const armpl_int_t *n,
                          const armpl_int_t *kl, const armpl_int_t *ku,
                          const armpl_int_t *nrhs, const float *ab,
                          const armpl_int_t *ldab, const float *afb,
                          const armpl_int_t *ldafb, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const float *c,
                          const float *b, const armpl_int_t *ldb, float *y,
                          const armpl_int_t *ldy, float *berr_out,
                          const armpl_int_t *n_norms, float *err_bnds_norm,
                          float *err_bnds_comp, float *res, float *ayb,
                          float *dy, float *y_tail, const float *rcond,
                          const armpl_int_t *ithresh, const float *rthresh,
                          const float *dz_ub, const armpl_int_t *ignore_cwise,
                          armpl_int_t *info);
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

TRANS_TYPE Input parameter.

TRANS_TYPE is INTEGER

Specifies the transposition operation on A. The value is defined by ILATRANS(T) where T is a CHARACTER and T = 'N': No transpose = 'T': Transpose = 'C': Conjugate transpose

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the N-by-N matrix AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= max(1, N).

AFB Input parameter.

AFB is REAL

AFB is an array, dimension (LDAFB, N). The factors L and U from the factorization A = P*L*U as computed by SGBTRF.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AF. LDAFB >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by SGBTRF; row i of the matrix was interchanged with row IPIV(i).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is REAL

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by SGBTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is REAL

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by SLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix

Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is REAL

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N). Workspace. This can be the same workspace passed for Y_TAIL.

DY Input parameter.

DY is REAL

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is REAL

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is REAL

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is REAL

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to SGBTRS had an illegal value

Related Information

For this routine in other precisions, please see *cla_gbrfsx_extended*, *dla_gbrfsx_extended* and *zla_gbrfsx_extended*.

4.17.430 sla_gbrpvgrw

SLA_GBRPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

real function sla_gbrpvgrw(N, KL, KU, NCOLS, AB, LDAB, AFB, LDAFB)
```

C specification:

```
#include "armpl.h"

float sla_gbrpvgrw_(const armpl_int_t *n, const armpl_int_t *kl,
                    const armpl_int_t *ku, const armpl_int_t *ncols,
                    const float *ab, const armpl_int_t *ldab,
                    const float *afb, const armpl_int_t *ldafb);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is REAL

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

Related Information

For this routine in other precisions, please see *cla_gbrpvgrw*, *dla_gbrpvgrw* and *zla_gbrpvgrw*.

4.17.431 sla_geamv

SLA_GEAMV performs one of the matrix-vector operations

```
     y := alpha*abs(A)*abs(x) + beta*abs(y),
or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine sla_geamv(TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void sla_geamv_(const armpl_int_t *trans, const armpl_int_t *m,
                const armpl_int_t *n, const float *alpha, const float *a,
                const armpl_int_t *lda, const float *x,
                const armpl_int_t *incx, const float *beta, float *y,
                const armpl_int_t *incy);
```

Parameters

TRANS Input parameter.

TRANS is INTEGER

On entry, TRANS specifies the operation to be performed as follows:

BLAS_NO_TRANS y := alpha*abs(A)*abs(x) + beta*abs(y) BLAS_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y) BLAS_CONJ_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y)

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is REAL

A is an array, dimension (LDA, n). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m). Unchanged on exit.

X Input parameter.

X is REAL

X is an array, dimension. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is REAL

Y is an array,. dimension at least (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Level 2 Blas routine.

Related Information

For this routine in other precisions, please see *cla_geamv*, *dla_geamv* and *zla_geamv*.

4.17.432 sla_gercond

```
SLA_GERCOND estimates the Skeel condition number of op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.
```

Syntax

Fortran specification:

```
use armpl_library

real function sla_gercond(TRANS, N, A, LDA, AF, LDAF, IPIV, CMODE, C, INFO,
                          WORK, IWORK)
```

C specification:

```
#include "armpl.h"

float sla_gercond_(const char *trans, const armpl_int_t *n, const float *a,
                   const armpl_int_t *lda, const float *af,
                   const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                   const armpl_int_t *cmode, const float *c,
                   armpl_int_t *info, float *work, armpl_int_t *iwork, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by SGETRF; row i of the matrix was interchanged with row IPIV(i).

CMODE Input parameter.

CMODE is INTEGER

Determines op2(C) in the formula op(A) * op2(C) as follows: CMODE = 1 op2(C) = C CMODE = 0 op2(C) = I CMODE = -1 op2(C) = inv(C)

C Input parameter.

C is REAL

C is an array, dimension (N). The vector C in the formula op(A) * op2(C).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is REAL

WORK is an array, dimension (3*N).. Workspace.

IWORK Input parameter.

IWORK is INTEGER array, dimension (N).

Workspace.2

Related Information

For this routine in other precisions, please see *dla_gercond*.

4.17.433 sla_gerfsx_extended

`sla_gerfsx_extended` improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by SGERFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERRS_N and ERRS_C for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERRS_N and ERRS_C.

Syntax

Fortran specification:

```
use armpl_library

subroutine sla_gerfsx_extended(PREC_TYPE, TRANS_TYPE, N, NRHS, A, LDA, AF,
                               LDAF, IPIV, COLEQU, C, B, LDB, Y, LDY,
                               BERR_OUT, N_NORMS, ERRS_N, ERRS_C, RES, AYB,
                               DY, Y_TAIL, RCOND, ITHRESH, RTHRESH, DZ_UB,
                               IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void sla_gerfsx_extended_(const armpl_int_t *prec_type,
                          const armpl_int_t *trans_type, const armpl_int_t *n,
                          const armpl_int_t *nrhs, const float *a,
                          const armpl_int_t *lda, const float *af,
                          const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const float *c,
                          const float *b, const armpl_int_t *ldb, float *y,
                          const armpl_int_t *ldy, float *berr_out,
                          const armpl_int_t *n_norms, float *errs_n,
                          float *errs_c, float *res, float *ayb, float *dy,
                          float *y_tail, const float *rcond,
                          const armpl_int_t *ithresh, const float *rthresh,
                          const float *dz_ub, const armpl_int_t *ignore_cwise,
                          armpl_int_t *info);
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = ‘S’: Single = ‘D’: Double = ‘I’: Indigenous = ‘X’, ‘E’: Extra

TRANS_TYPE Input parameter.

TRANS_TYPE is INTEGER

Specifies the transposition operation on A. The value is defined by ILATRANS(T) where T is a CHARACTER and T = ‘N’: No transpose = ‘T’: Transpose = ‘C’: Conjugate transpose

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by SGETRF; row i of the matrix was interchanged with row IPIV(i).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is REAL

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is REAL

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by SLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERRS_N and ERRS_C). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERRS_N Input and output parameter.

ERRS_N is REAL

ERRS_N is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERRS_N(i,:) corresponds to the ith right-hand side.

The second index in ERRS_N(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERRS_C Input and output parameter.

ERRS_C is REAL

ERRS_C is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERRS_C is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERRS_C(i,:) corresponds to the ith right-hand side.

The second index in ERRS_C(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is REAL

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N). Workspace. This can be the same workspace passed for Y_TAIL.

DY Input parameter.

DY is REAL

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is REAL

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For ‘aggressive’ set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERRS_N and ERRS_C may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is REAL

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For ‘aggressive’ set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is REAL

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each

component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to SGETRS had an illegal value

For this routine in other precisions, please see *cla_gerfsx_extended*, *dla_gerfsx_extended* and *zla_gerfsx_extended*.

4.17.434 sla_gerpvgrw

SLA_GERPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

real function sla_gerpvgrw(N, NCOLS, A, LDA, AF, LDAF)
```

C specification:

```
#include "armpl.h"

float sla_gerpvgrw_(const armpl_int_t *n, const armpl_int_t *ncols,
                    const float *a, const armpl_int_t *lda, const float *af,
                    const armpl_int_t *ldaf);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

Related Information

For this routine in other precisions, please see *cla_gerpvgrw*, *dla_gerpvgrw* and *zla_gerpvgrw*.

4.17.435 sla_lin_berr

```
SLA_LIN_BERR computes componentwise relative backward error from
   the formula
       max(i) ( abs(R(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
   where abs(Z) is the componentwise absolute value of the matrix
   or vector Z.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sla_lin_berr(N, NZ, NRHS, RES, AYB, BERR)
```

C specification:

```
#include "armpl.h"

void sla_lin_berr_(const armpl_int_t *n, const armpl_int_t *nz,
                   const armpl_int_t *nrhs, const float *res,
                   const float *ayb, float *berr);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NZ Input parameter.

NZ is INTEGER

We add (NZ+1)*SLAMCH('Safe minimum') to R(i) in the numerator to guard against spuriously zero residuals. Default value is N.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices AYB, RES, and BERR. NRHS >= 0.

RES Input parameter.

RES is REAL

RES is an array, dimension (N, NRHS). The residual matrix, i.e., the matrix R in the relative backward error formula above.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N, NRHS). The denominator in the relative backward error formula above, i.e., the matrix abs(op(A_s))*abs(Y) + abs(B_s). The matrices A, Y, and B are from iterative refinement (see sla_gerfsx_extended.f).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error from the formula above.

Related Information

For this routine in other precisions, please see *cla_lin_berr*, *dla_lin_berr* and *zla_lin_berr*.

4.17.436 sla_porcond

```
SLA_PORCOND Estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number  cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.
```

Syntax

Fortran specification:

```
use armpl_library

real function sla_porcond(UPLO, N, A, LDA, AF, LDAF, CMODE, C, INFO, WORK,
                          IWORK)
```

C specification:

```
#include "armpl.h"

float sla_porcond_(const char *uplo, const armpl_int_t *n, const float *a,
                   const armpl_int_t *lda, const float *af,
                   const armpl_int_t *ldaf, const armpl_int_t *cmode,
                   const float *c, armpl_int_t *info, float *work,
                   armpl_int_t *iwork, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

CMODE Input parameter.

CMODE is INTEGER

Determines op2(C) in the formula op(A) * op2(C) as follows: CMODE = 1 op2(C) = C CMODE = 0 op2(C) = I CMODE = -1 op2(C) = inv(C)

C Input parameter.

C is REAL

C is an array, dimension (N). The vector C in the formula op(A) * op2(C).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is REAL

WORK is an array, dimension (3*N).. Workspace.

IWORK Input parameter.

IWORK is INTEGER array, dimension (N).

Workspace.

Related Information

For this routine in other precisions, please see *dla_porcond*.

4.17.437 sla_porfsx_extended

sla_porfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by SPORFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine sla_porfsx_extended(PREC_TYPE, UPLO, N, NRHS, A, LDA, AF, LDAF,
                               COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS,
                               ERR_BNDS_NORM, ERR_BNDS_COMP, RES, AYB, DY,
                               Y_TAIL, RCOND, ITHRESH, RTHRESH, DZ_UB,
                               IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void sla_porfsx_extended_(const armpl_int_t *prec_type, const char *uplo,
                          const armpl_int_t *n, const armpl_int_t *nrhs,
                          const float *a, const armpl_int_t *lda,
                          const float *af, const armpl_int_t *ldaf,
                          const armpl_int_t *colequ, const float *c,
                          const float *b, const armpl_int_t *ldb, float *y,
                          const armpl_int_t *ldy, float *berr_out,
                          const armpl_int_t *n_norms, float *err_bnds_norm,
                          float *err_bnds_comp, float *res, float *ayb,
                          float *dy, float *y_tail, const float *rcond,
                          const armpl_int_t *ithresh, const float *rthresh,
                          const float *dz_ub, const armpl_int_t *ignore_cwise,
                          armpl_int_t *info, ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is REAL

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by SPOTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is REAL

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s)

)(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by SLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is REAL

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N). Workspace. This can be the same workspace passed for Y_TAIL.

DY Input parameter.

DY is REAL

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is REAL

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is REAL

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is REAL

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to SPOTRS had an illegal value

4.17.438 sla_porpvgrw

SLA_PORPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

real function sla_porpvgrw(UPLO, NCOLS, A, LDA, AF, LDAF, WORK)
```

C specification:

```
#include "armpl.h"

float sla_porpvgrw_(const char *uplo, const armpl_int_t *ncols,
                    const float *a, const armpl_int_t *lda, const float *af,
                    const armpl_int_t *ldaf, float *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA,N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1,N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF,N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1,N).

WORK Input parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *cla_porpvgrw*, *dla_porpvgrw* and *zla_porpvgrw*.

4.17.439 sla_syamv

SLA_SYAMV performs the matrix-vector operation

```
y := alpha*abs(A)*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an n by n symmetric matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine sla_syamv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void sla_syamv_(const armpl_int_t *uplo, const armpl_int_t *n,
                const float *alpha, const float *a, const armpl_int_t *lda,
                const float *x, const armpl_int_t *incx, const float *beta,
                float *y, const armpl_int_t *incy);
```

Parameters

UPLO Input parameter.

UPLO is INTEGER

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = BLAS_UPPER Only the upper triangular part of A is to be referenced.

UPLO = BLAS_LOWER Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is REAL .

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is REAL

A is an array, dimension (LDA, n).. Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n). Unchanged on exit.

X Input parameter.

X is REAL

X is an array, dimension. (1 + (n - 1)*abs(INCX)) Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is REAL .

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is REAL

Y is an array, dimension. (1 + (n - 1)*abs(INCY)) Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Related Information

For this routine in other precisions, please see *cla_syamv*, *dla_syamv* and *zla_syamv*.

4.17.440 sla_syrcond

```
SLA_SYRCOND estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.
```

Syntax

Fortran specification:

```
use armpl_library

real function sla_syrcond(UPLO, N, A, LDA, AF, LDAF, IPIV, CMODE, C, INFO,
                          WORK, IWORK)
```

C specification:

```
#include "armpl.h"

float sla_syrcond_(const char *uplo, const armpl_int_t *n, const float *a,
                   const armpl_int_t *lda, const float *af,
                   const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                   const armpl_int_t *cmode, const float *c,
                   armpl_int_t *info, float *work, armpl_int_t *iwork, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

CMODE Input parameter.

CMODE is INTEGER

Determines op2(C) in the formula op(A) * op2(C) as follows: CMODE = 1 op2(C) = C CMODE = 0 op2(C) = I CMODE = -1 op2(C) = inv(C)

C Input parameter.

C is REAL

C is an array, dimension (N). The vector C in the formula op(A) * op2(C).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is REAL

WORK is an array, dimension (3*N).. Workspace.

IWORK Input parameter.

IWORK is INTEGER array, dimension (N).

Workspace.

For this routine in other precisions, please see *dla_syrcond*.

4.17.441 sla_syrfsx_extended

sla_syrfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by SSYRFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine sla_syrfsx_extended(PREC_TYPE, UPLO, N, NRHS, A, LDA, AF, LDAF,
                               IPIV, COLEQU, C, B, LDB, Y, LDY, BERR_OUT,
                               N_NORMS, ERR_BNDS_NORM, ERR_BNDS_COMP, RES,
```

(continues on next page)

(continued from previous page)

```
                                AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
                                DZ_UB, IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void sla_syrfsx_extended_(const armpl_int_t *prec_type, const char *uplo,
                          const armpl_int_t *n, const armpl_int_t *nrhs,
                          const float *a, const armpl_int_t *lda,
                          const float *af, const armpl_int_t *ldaf,
                          const armpl_int_t *ipiv, const armpl_int_t *colequ,
                          const float *c, const float *b,
                          const armpl_int_t *ldb, float *y,
                          const armpl_int_t *ldy, float *berr_out,
                          const armpl_int_t *n_norms, float *err_bnds_norm,
                          float *err_bnds_comp, float *res, float *ayb,
                          float *dy, float *y_tail, const float *rcond,
                          const armpl_int_t *ithresh, const float *rthresh,
                          const float *dz_ub, const armpl_int_t *ignore_cwise,
                          armpl_int_t *info, ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is REAL

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by SSYTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is REAL

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by SLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is REAL

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N). Workspace. This can be the same workspace passed for Y_TAIL.

DY Input parameter.

DY is REAL

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is REAL

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is REAL

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is REAL

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to SLA_SYRFSX_EXTENDED had an illegal value

Related Information

For this routine in other precisions, please see *cla_syrfsx_extended*, *dla_syrfsx_extended* and *zla_syrfsx_extended*.

4.17.442 sla_syrpvgrw

SLA_SYRPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The “max absolute element” norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

real function sla_syrpvgrw(UPLO, N, INFO, A, LDA, AF, LDAF, IPIV, WORK)
```

C specification:

```
#include "armpl.h"

float sla_syrpvgrw_(const char *uplo, const armpl_int_t *n,
                    const armpl_int_t *info, const float *a,
                    const armpl_int_t *lda, const float *af,
                    const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                    float *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= ‘U’: Upper triangle of A is stored; = ‘L’: Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

INFO Input parameter.

INFO is INTEGER

The value of INFO returned from SSYTRF, .i.e., the pivot in column INFO is exactly 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is REAL

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

WORK Input parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *cla_syrpvgrw*, *dla_syrpvgrw* and *zla_syrpvgrw*.

4.17.443 sla_wwaddw

```
SLA_WWADDW adds a vector W into a doubled-single vector (X, Y).

   This works for all extant IBM's hex and binary floating point
   arithmetics, but not for decimal.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sla_wwaddw(N, X, Y, W)
```

C specification:

```
#include "armpl.h"

void sla_wwaddw_(const armpl_int_t *n, float *x, float *y, const float *w);
```

Parameters

N Input parameter.

N is INTEGER

The length of vectors X, Y, and W.

X Input and output parameter.

X is REAL

X is an array, dimension (N). The first part of the doubled-single accumulation vector.

Y Input and output parameter.

Y is REAL

Y is an array, dimension (N). The second part of the doubled-single accumulation vector.

W Input parameter.

W is REAL

W is an array, dimension (N). The vector to be added.

Related Information

For this routine in other precisions, please see *cla_wwaddw*, *dla_wwaddw* and *zla_wwaddw*.

4.17.444 slabrd

`slabrd` reduces the first NB rows and columns of a real general m by n matrix A to upper or lower bidiagonal form by an orthogonal transformation Q^T * A * P, and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A.

If m >= n, A is reduced to upper bidiagonal form; if m < n, to lower bidiagonal form.

This is an auxiliary routine called by SGEBRD

Syntax

Fortran specification:

```
use armpl_library

subroutine slabrd(M, N, NB, A, LDA, D, E, TAUQ, TAUP, X, LDX, Y, LDY)
```

C specification:

```
#include "armpl.h"

void slabrd_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nb, float *a, const armpl_int_t *lda,
             float *d, float *e, float *tauq, float *taup, float *x,
             const armpl_int_t *ldx, float *y, const armpl_int_t *ldy);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A.

N Input parameter.

N is INTEGER

The number of columns in the matrix A.

NB Input parameter.

NB is INTEGER

The number of leading rows and columns of A to be reduced.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the m by n general matrix to be reduced. On exit, the first NB rows and columns of the matrix are overwritten; the rest of the array is unchanged. If m >= n, elements on and below the diagonal in the first NB columns, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors; and elements above the diagonal in the first NB rows, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. If m < n, elements below the diagonal in the first NB columns, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first NB rows, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is REAL

D is an array, dimension (NB). The diagonal elements of the first NB rows and columns of the reduced matrix. D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (NB). The off-diagonal elements of the first NB rows and columns of the reduced matrix.

TAUQ Output parameter.

TAUQ is REAL

TAUQ is an array, dimension (NB). The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

TAUP Output parameter.

TAUP is REAL

TAUP is an array, dimension (NB). The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

X Output parameter.

X is REAL

X is an array, dimension (LDX, NB). The m-by-nb matrix X required to update the unreduced part of A.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, M).

Y Output parameter.

Y is REAL

Y is an array, dimension (LDY, NB). The n-by-nb matrix Y required to update the unreduced part of A.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

Related Information

For this routine in other precisions, please see *clabrd*, *dlabrd* and *zlabrd*.

4.17.445 slacn2

slacn2 estimates the 1-norm of a square, real matrix A. Reverse communication is used for evaluating matrix-vector products.

Syntax

Fortran specification:

```
use armpl_library

subroutine slacn2(N, V, X, ISGN, EST, KASE, ISAVE)
```

C specification:

```
#include "armpl.h"

void slacn2_(const armpl_int_t *n, float *v, float *x, armpl_int_t *isgn,
             float *est, armpl_int_t *kase, armpl_int_t *isave);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 1.

V Output parameter.

V is REAL

V is an array, dimension (N). On the final return, V = A*W, where EST = norm(V)/norm(W) (W is not returned).

X Input and output parameter.

X is REAL

X is an array, dimension (N). On an intermediate return, X should be overwritten by A * X, if KASE=1, A^T * X, if KASE=2, and SLACN2 must be re-called with all the other parameters unchanged.

ISGN Output parameter.

ISGN is INTEGER array, dimension (N)

EST Input and output parameter.

EST is REAL

On entry with KASE = 1 or 2 and ISAVE(1) = 3, EST should be unchanged from the previous call to SLACN2. On exit, EST is an estimate (a lower bound) for norm(A).

KASE Input and output parameter.

KASE is INTEGER

On the initial call to SLACN2, KASE should be 0. On an intermediate return, KASE will be 1 or 2, indicating whether X should be overwritten by A * X or A^T * X. On the final return from SLACN2, KASE will again be 0.

ISAVE Input and output parameter.

ISAVE is INTEGER array, dimension (3)

ISAVE is used to save variables between calls to SLACN2

Related Information

For this routine in other precisions, please see *clacn2*, *dlacn2* and *zlacn2*. It also exists with a native C interface as *LAPACKE_slacn2*.

4.17.446 slacon

`slacon` estimates the 1-norm of a square, real matrix A. Reverse communication is used for evaluating matrix-vector products.

Syntax

Fortran specification:

```
use armpl_library

subroutine slacon(N, V, X, ISGN, EST, KASE)
```

C specification:

```
#include "armpl.h"

void slacon_(const armpl_int_t *n, float *v, float *x, armpl_int_t *isgn,
             float *est, armpl_int_t *kase);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 1.

V Output parameter.

V is REAL

V is an array, dimension (N). On the final return, V = A*W, where EST = norm(V)/norm(W) (W is not returned).

X Input and output parameter.

X is REAL

X is an array, dimension (N). On an intermediate return, X should be overwritten by A * X, if KASE=1, A^T * X, if KASE=2, and SLACON must be re-called with all the other parameters unchanged.

ISGN Output parameter.

ISGN is INTEGER array, dimension (N)

EST Input and output parameter.

EST is REAL

On entry with KASE = 1 or 2 and JUMP = 3, EST should be unchanged from the previous call to SLACON. On exit, EST is an estimate (a lower bound) for norm(A).

KASE Input and output parameter.

KASE is INTEGER

On the initial call to SLACON, KASE should be 0. On an intermediate return, KASE will be 1 or 2, indicating whether X should be overwritten by A * X or A^T * X. On the final return from SLACON, KASE will again be 0.

Related Information

4.17.447 slacpy

`slacpy` copies all or part of a two-dimensional matrix A to another matrix B.

Syntax

Fortran specification:

```
use armpl_library

subroutine slacpy(UPLO, M, N, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void slacpy_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be copied to B. = 'U': Upper triangular part = 'L': Lower triangular part Otherwise: All of the matrix A

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The m by n matrix A. If UPLO = 'U', only the upper triangle or trapezoid is accessed; if UPLO = 'L', only the lower triangle or trapezoid is accessed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Output parameter.

B is REAL

B is an array, dimension (LDB, N). On exit, B = A in the locations specified by UPLO.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

Related Information

For this routine in other precisions, please see *clacpy*, *dlacpy* and *zlacpy*. It also exists with a native C interface as *LAPACKE_slacpy*.

4.17.448 sladiv

`sladiv` performs complex division in real arithmetic

```
            a + i*b
p + i*q = ---------
            c + i*d
```

The algorithm is due to Michael Baudin and Robert L. Smith and can be found in the paper "A Robust Complex Division in Scilab"

Syntax

Fortran specification:

```
use armpl_library

subroutine sladiv(A, B, C, D, P, Q)
```

C specification:

```
#include "armpl.h"

void sladiv_(const float *a, const float *b, const float *c, const float *d,
             float *p, float *q);
```

Parameters

A Input parameter.

A is REAL

B Input parameter.

B is REAL

C Input parameter.

C is REAL

D Input parameter.

D is REAL

The scalars a, b, c, and d in the above expression.

P Output parameter.

P is REAL

Q Output parameter.

Q is REAL

The scalars p and q in the above expression.

Related Information

For this routine in other precisions, please see *cladiv*, *dladiv* and *zladiv*.

4.17.449 slae2

`slae2` computes the eigenvalues of a 2-by-2 symmetric matrix

```
[  A   B  ]
[  B   C  ].
```

On return, RT1 is the eigenvalue of larger absolute value, and RT2 is the eigenvalue of smaller absolute value.

Syntax

Fortran specification:

```
use armpl_library

subroutine slae2(A, B, C, RT1, RT2)
```

C specification:

```
#include "armpl.h"

void slae2_(const float *a, const float *b, const float *c, float *rt1,
            float *rt2);
```

Parameters

A Input parameter.

A is REAL

The (1,1) element of the 2-by-2 matrix.

B Input parameter.

B is REAL

The (1,2) and (2,1) elements of the 2-by-2 matrix.

C Input parameter.

C is REAL

The (2,2) element of the 2-by-2 matrix.

RT1 Output parameter.

RT1 is REAL

The eigenvalue of larger absolute value.

RT2 Output parameter.

RT2 is REAL

The eigenvalue of smaller absolute value.

Related Information

For this routine in other precisions, please see *dlae2*.

4.17.450 slaebz

`slaebz` contains the iteration loops which compute and use the function N(w), which is the count of eigenvalues of a symmetric tridiagonal matrix T less than or equal to its argument w. It performs a choice of two types of loops:

IJOB=1, followed by IJOB=2: It takes as input a list of intervals and returns a list of

```
sufficiently small intervals whose union contains the same
eigenvalues as the union of the original intervals.
The input intervals are (AB(j,1),AB(j,2)], j=1,...,MINP.
The output interval (AB(j,1),AB(j,2)] will contain
eigenvalues NAB(j,1)+1,...,NAB(j,2), where 1 <= j <= MOUT.
```

IJOB=3: It performs a binary search in each input interval

```
(AB(j,1),AB(j,2)] for a point  w(j)  such that
N(w(j))=NVAL(j), and uses  C(j)  as the starting point of
the search.  If such a w(j) is found, then on output
AB(j,1)=AB(j,2)=w.  If no such w(j) is found, then on output
(AB(j,1),AB(j,2)] will be a small interval containing the
point where N(w) jumps through NVAL(j), unless that point
lies outside the initial interval.
```

Note that the intervals are in all cases half-open intervals, i.e., of the form (a,b] , which includes b but not a .

To avoid underflow, the matrix should be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value. To assure the most accurate computation of small eigenvalues, the matrix should be scaled to be not much smaller than that, either.

See W. Kahan “Accurate Eigenvalues of a Symmetric Tridiagonal Matrix”, Report CS41, Computer Science Dept., Stanford University, July 21, 1966

Note: the arguments are, in general, *not* checked for unreasonable values.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaebz(IJOB, NITMAX, N, MMAX, MINP, NBMIN, ABSTOL, RELTOL, PIVMIN,
                  D, E, E2, NVAL, AB, C, MOUT, NAB, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slaebz_(const armpl_int_t *ijob, const armpl_int_t *nitmax,
             const armpl_int_t *n, const armpl_int_t *mmax,
             const armpl_int_t *minp, const armpl_int_t *nbmin,
             const float *abstol, const float *reltol, const float *pivmin,
             const float *d, const float *e, const float *e2,
             armpl_int_t *nval, float *ab, float *c, armpl_int_t *mout,
             armpl_int_t *nab, float *work, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

IJOB Input parameter.

IJOB is INTEGER

Specifies what is to be done: = 1: Compute NAB for the initial intervals. = 2: Perform bisection iteration to find eigenvalues of T. = 3: Perform bisection iteration to invert N(w), i.e., to find a point which has a specified number of eigenvalues of T to its left. Other values will cause SLAEBZ to return with INFO=-1.

NITMAX Input parameter.

NITMAX is INTEGER

The maximum number of "levels" of bisection to be performed, i.e., an interval of width W will not be made smaller than 2^(-NITMAX) * W. If not all intervals have converged after NITMAX iterations, then INFO is set to the number of non-converged intervals.

N Input parameter.

N is INTEGER

The dimension n of the tridiagonal matrix T. It must be at least 1.

MMAX Input parameter.

MMAX is INTEGER

The maximum number of intervals. If more than MMAX intervals are generated, then SLAEBZ will quit with INFO=MMAX+1.

MINP Input parameter.

MINP is INTEGER

The initial number of intervals. It may not be greater than MMAX.

NBMIN Input parameter.

NBMIN is INTEGER

The smallest number of intervals that should be processed using a vector loop. If zero, then only the scalar loop will be used.

ABSTOL Input parameter.

ABSTOL is REAL

The minimum (absolute) width of an interval. When an interval is narrower than ABSTOL, or than RELTOL times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. This must be at least zero.

RELTOL Input parameter.

RELTOL is REAL

The minimum relative width of an interval. When an interval is narrower than ABSTOL, or than RELTOL times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum absolute value of a "pivot" in the Sturm sequence loop. This must be at least max |e(j)**2|*safe_min and at least safe_min, where safe_min is at least the smallest number that can divide one without overflow.

D Input parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is REAL

E is an array, dimension (N). The offdiagonal elements of the tridiagonal matrix T in positions 1 through N-1. E(N) is arbitrary.

E2 Input parameter.

E2 is REAL

E2 is an array, dimension (N). The squares of the offdiagonal elements of the tridiagonal matrix T. E2(N) is ignored.

NVAL Input and output parameter.

NVAL is INTEGER array, dimension (MINP)

If IJOB=1 or 2, not referenced. If IJOB=3, the desired values of N(w). The elements of NVAL will be reordered to correspond with the intervals in AB. Thus, NVAL(j) on output will not, in general be the same as NVAL(j) on input, but it will correspond with the interval (AB(j,1),AB(j,2)] on output.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (MMAX,2). The endpoints of the intervals. AB(j,1) is a(j), the left endpoint of the j-th interval, and AB(j,2) is b(j), the right endpoint of the j-th interval. The input intervals will, in general, be modified, split, and reordered by the calculation.

C Input and output parameter.

C is REAL

C is an array, dimension (MMAX). If IJOB=1, ignored. If IJOB=2, workspace. If IJOB=3, then on input C(j) should be initialized to the first search point in the binary search.

MOUT Output parameter.

MOUT is INTEGER

If IJOB=1, the number of eigenvalues in the intervals. If IJOB=2 or 3, the number of intervals output. If IJOB=3, MOUT will equal MINP.

NAB Input and output parameter.

NAB is INTEGER array, dimension (MMAX,2)

If IJOB=1, then on output NAB(i,j) will be set to N(AB(i,j)). If IJOB=2, then on input, NAB(i,j) should be set. It must satisfy the condition: N(AB(i,1)) <= NAB(i,1) <= NAB(i,2) <= N(AB(i,2)), which means that in interval i only eigenvalues NAB(i,1)+1,...,NAB(i,2) will be considered. Usually, NAB(i,j)=N(AB(i,j)), from a previous call to SLAEBZ with IJOB=1. On output, NAB(i,j) will contain max(na(k),min(nb(k),N(AB(i,j)))), where k is the index of the input interval that the output interval (AB(j,1),AB(j,2)] came from, and na(k) and nb(k) are the the input values of NAB(k,1) and NAB(k,2). If IJOB=3, then on output, NAB(i,j) contains N(AB(i,j)), unless N(w) > NVAL(i) for all search points w , in which case NAB(i,1) will not be modified, i.e., the output value will be the same as the input value (modulo reorderings – see NVAL and AB), or unless N(w) < NVAL(i) for all search points w , in which case NAB(i,2) will not be modified. Normally, NAB should be set to some distinctive value(s) before SLAEBZ is called.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MMAX). Workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MMAX)

Workspace.

INFO Output parameter.

INFO is INTEGER

= 0: All intervals converged. = 1–MMAX: The last INFO intervals did not converge. = MMAX+1: More than MMAX intervals were generated.

Related Information

For this routine in other precisions, please see *dlaebz*.

4.17.451 slaed0

slaed0 computes all eigenvalues and corresponding eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed0(ICOMPQ, QSIZ, N, D, E, Q, LDQ, QSTORE, LDQS, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void slaed0_(const armpl_int_t *icompq, const armpl_int_t *qsiz,
             const armpl_int_t *n, float *d, const float *e, float *q,
             const armpl_int_t *ldq, float *qstore, const armpl_int_t *ldqs,
             float *work, armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

= 0: Compute eigenvalues only. = 1: Compute eigenvectors of original dense symmetric matrix also. On entry, Q contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 2: Compute eigenvalues and eigenvectors of tridiagonal matrix.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the orthogonal matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the main diagonal of the tridiagonal matrix. On exit, its eigenvalues.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, Q must contain an N-by-N orthogonal matrix. If ICOMPQ = 0 Q is not referenced. If ICOMPQ = 1 On entry, Q is a subset of the columns of the orthogonal matrix used to reduce the full matrix to tridiagonal form corresponding to the subset of the full matrix which is being decomposed at this time. If ICOMPQ = 2 On entry, Q will be the identity matrix. On exit, Q contains the eigenvectors of the tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If eigenvectors are desired, then LDQ >= max(1, N). In any case, LDQ >= 1.

QSTORE Output parameter.

QSTORE is REAL

QSTORE is an array, dimension (LDQS, N). Referenced only when ICOMPQ = 1. Used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

LDQS Input parameter.

LDQS is INTEGER

The leading dimension of the array QSTORE. If ICOMPQ = 1, then LDQS >= max(1, N). In any case, LDQS >= 1.

WORK Output parameter.

WORK is REAL

WORK is an array,. If ICOMPQ = 0 or 1, the dimension of WORK must be at least 1 + 3* N + 2*N*lg N + 3*N**2 (lg(N) = smallest integer k such that 2^k >= N) If ICOMPQ = 2, the dimension of WORK must be at least 4* N + N**2.

IWORK Output parameter.

IWORK is INTEGER array,

If ICOMPQ = 0 or 1, the dimension of IWORK must be at least 6 + 6* N + 5*N*lg N. (lg(N) = smallest integer k such that 2^k >= N) If ICOMPQ = 2, the dimension of IWORK must be at least 3 + 5*N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *claed0*, *dlaed0* and *zlaed0*.

4.17.452 slaed1

slaed1 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and eigenvectors of a tridiagonal matrix. SLAED7 handles the case in which eigenvalues only or eigenvalues and eigenvectors of a full symmetric matrix (which was reduced to tridiagonal form) are desired.

```
T = Q(in) ( D(in) + RHO * Z*Z**T ) Q**T(in) = Q(out) * D(out) * Q**T(out)

where Z = Q**T*u, u is a vector of length N with ones in the
CUTPNT and CUTPNT + 1 th elements and zeros elsewhere.

The eigenvectors of the original matrix are stored in Q, and the
eigenvalues are in D.  The algorithm consists of three stages:

   The first stage consists of deflating the size of the problem
   when there are multiple eigenvalues or if there is a zero in
   the Z vector.  For each such occurrence the dimension of the
   secular equation problem is reduced by one.  This stage is
   performed by the routine SLAED2.

   The second stage consists of calculating the updated
   eigenvalues. This is done by finding the roots of the secular
   equation via the routine SLAED4 (as called by SLAED3).
   This routine also calculates the eigenvectors of the current
   problem.

   The final stage consists of computing the updated eigenvectors
   directly using the updated eigenvalues.  The eigenvectors for
   the current problem are multiplied with the eigenvectors from
   the overall problem.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed1(N, D, Q, LDQ, INDXQ, RHO, CUTPNT, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slaed1_(const armpl_int_t *n, float *d, float *q, const armpl_int_t *ldq,
             armpl_int_t *indxq, const float *rho, const armpl_int_t *cutpnt,
             float *work, armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the eigenvalues of the rank-1-perturbed matrix. On exit, the eigenvalues of the repaired matrix.

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, the eigenvectors of the rank-1-perturbed matrix. On exit, the eigenvectors of the repaired tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

INDXQ Input and output parameter.

INDXQ is INTEGER array, dimension (N)

On entry, the permutation which separately sorts the two subproblems in D into ascending order. On exit, the permutation which will reintegrate the subproblems back into sorted order, i.e. D(INDXQ(I = 1, N)) will be in ascending order.

RHO Input parameter.

RHO is REAL

The subdiagonal entry used to create the rank-1 modification.

CUTPNT Input parameter.

CUTPNT is INTEGER

The location of the last eigenvalue in the leading sub-matrix. min(1, N) <= CUTPNT <= N/2.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4* N + N2)** .

IWORK Output parameter.

IWORK is INTEGER array, dimension (4*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *dlaed1*.

4.17.453 slaed2

slaed2 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed2(K, N, N1, D, Q, LDQ, INDXQ, RHO, Z, DLAMDA, W, Q2, INDX,
                  INDXC, INDXP, COLTYP, INFO)
```

C specification:

```
#include "armpl.h"

void slaed2_(armpl_int_t *k, const armpl_int_t *n, const armpl_int_t *n1,
             float *d, float *q, const armpl_int_t *ldq, armpl_int_t *indxq,
             float *rho, const float *z, float *dlamda, float *w, float *q2,
             armpl_int_t *indx, armpl_int_t *indxc, armpl_int_t *indxp,
             armpl_int_t *coltyp, armpl_int_t *info);
```

Parameters

K Output parameter.

K is INTEGER

The number of non-deflated eigenvalues, and the order of the related secular equation. 0 <= K <=N.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

N1 Input parameter.

N1 is INTEGER

The location of the last eigenvalue in the leading sub-matrix. min(1, N) <= N1 <= N/2.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, D contains the eigenvalues of the two submatrices to be combined. On exit, D contains the trailing (N-K) updated eigenvalues (those which were deflated) sorted into increasing order.

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, Q contains the eigenvectors of two submatrices in the two square blocks with corners at (1,1), (N1, N1) and (N1+1, N1+1), (N, N). On exit, Q contains the trailing (N-K) updated eigenvectors (those which were deflated) in its last N-K columns.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

INDXQ Input and output parameter.

INDXQ is INTEGER array, dimension (N)

The permutation which separately sorts the two sub-problems in D into ascending order. Note that elements in the second half of this permutation must first have N1 added to their values. Destroyed on exit.

RHO Input and output parameter.

RHO is REAL

On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined. On exit, RHO has been modified to the value required by SLAED3.

Z Input parameter.

Z is REAL

Z is an array, dimension (N). On entry, Z contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). On exit, the contents of Z have been destroyed by the updating process.

DLAMDA Output parameter.

DLAMDA is REAL

DLAMDA is an array, dimension (N). A copy of the first K eigenvalues which will be used by SLAED3 to form the secular equation.

W Output parameter.

W is REAL

W is an array, dimension (N). The first k values of the final deflation-altered z-vector which will be passed to SLAED3.

Q2 Output parameter.

Q2 is REAL

Q2 is an array, dimension (N1**2+(N-N1)**2). A copy of the first K eigenvectors which will be used by SLAED3 in a matrix multiply (SGEMM) to solve for the new eigenvectors.

INDX Output parameter.

INDX is INTEGER array, dimension (N)

The permutation used to sort the contents of DLAMDA into ascending order.

INDXC Output parameter.

INDXC is INTEGER array, dimension (N)

The permutation used to arrange the columns of the deflated Q matrix into three groups: the first group contains non-zero elements only at and above N1, the second contains non-zero elements only below N1, and the third is dense.

INDXP Output parameter.

INDXP is INTEGER array, dimension (N)

The permutation used to place deflated values of D at the end of the array. INDXP(1:K) points to the nondeflated D-values and INDXP(K+1:N) points to the deflated eigenvalues.

COLTYP Output parameter.

COLTYP is INTEGER array, dimension (N)

During execution, a label which will indicate which of the following types a column in the Q2 matrix is: 1 : non-zero in the upper half only; 2 : dense; 3 : non-zero in the lower half only; 4 : deflated. On exit, COLTYP(i) is the number of columns of type i, for i=1 to 4 only.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dlaed2*.

4.17.454 slaed3

`slaed3` finds the roots of the secular equation, as defined by the values in D, W, and RHO, between 1 and K. It makes the appropriate calls to SLAED4 and then updates the eigenvectors by multiplying the matrix of eigenvectors of the pair of eigensystems being combined by the matrix of eigenvectors of the K-by-K system which is solved here.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed3(K, N, N1, D, Q, LDQ, RHO, DLAMDA, Q2, INDX, CTOT, W, S,
                  INFO)
```

C specification:

```
#include "armpl.h"

void slaed3_(const armpl_int_t *k, const armpl_int_t *n,
             const armpl_int_t *n1, float *d, float *q,
             const armpl_int_t *ldq, const float *rho, float *dlamda,
             const float *q2, const armpl_int_t *indx,
             const armpl_int_t *ctot, float *w, float *s, armpl_int_t *info);
```

Parameters

K Input parameter.

`K` is `INTEGER`

The number of terms in the rational function to be solved by SLAED4. `K` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of rows and columns in the `Q` matrix. `N` >= `K` (deflation may result in N>K).

N1 Input parameter.

`N1` is `INTEGER`

The location of the last eigenvalue in the leading submatrix. min(1, `N`) <= `N1` <= N/2.

D Output parameter.

`D` is `REAL`

`D` is an array, dimension (`N`). D(I) contains the updated eigenvalues for 1 <= I <= `K`.

Q Output parameter.

`Q` is `REAL`

`Q` is an array, dimension (`LDQ`, `N`). Initially the first `K` columns are used as workspace. On output the columns 1 to `K` contain the updated eigenvectors.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

RHO Input parameter.

RHO is REAL

The value of the parameter in the rank one update equation. RHO >= 0 required.

DLAMDA Input and output parameter.

DLAMDA is REAL

DLAMDA is an array, dimension (K). The first K elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation. May be changed on output by having lowest order bit set to zero on Cray X-MP, Cray Y-MP, Cray-2, or Cray C-90, as described above.

Q2 Input parameter.

Q2 is REAL

Q2 is an array, dimension (LDQ2*N). The first K columns of this matrix contain the non-deflated eigenvectors for the split problem.

INDX Input parameter.

INDX is INTEGER array, dimension (N)

The permutation used to arrange the columns of the deflated Q matrix into three groups (see SLAED2). The rows of the eigenvectors found by SLAED4 must be likewise permuted before the matrix multiply can take place.

CTOT Input parameter.

CTOT is INTEGER array, dimension (4)

A count of the total number of the various types of columns in Q, as described in INDX. The fourth column type is any column which has been deflated.

W Input and output parameter.

W is REAL

W is an array, dimension (K). The first K elements of this array contain the components of the deflation-adjusted updating vector. Destroyed on output.

S Output parameter.

S is REAL

S is an array, dimension (N1 + 1)*K. Will contain the eigenvectors of the repaired matrix which will be multiplied by the previously accumulated eigenvectors to update the system.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *dlaed3*.

4.17.455 slaed4

This subroutine computes the I-th updated eigenvalue of a symmetric rank-one modification to a diagonal matrix whose elements are given in the array d, and that

```
D(i) < D(j)  for  i < j
```

and that RHO > 0. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

```
diag( D )  +  RHO * Z * Z_transpose.
```

where we assume the Euclidean norm of Z is 1.

The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed4(N, I, D, Z, DELTA, RHO, DLAM, INFO)
```

C specification:

```
#include "armpl.h"

void slaed4_(const armpl_int_t *n, const armpl_int_t *i, const float *d,
             const float *z, float *delta, const float *rho, float *dlam,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The length of all arrays.

I Input parameter.

I is INTEGER

The index of the eigenvalue to be computed. 1 <= I <= N.

D Input parameter.

D is REAL

D is an array, dimension (N). The original eigenvalues. It is assumed that they are in order, D(I) < D(J) for I < J.

Z Input parameter.

Z is REAL

Z is an array, dimension (N). The components of the updating vector.

DELTA Output parameter.

DELTA is REAL

DELTA is an array, dimension (N). If N .GT. 2, DELTA contains (D(j) - lambda_I) in its j-th component. If N = 1, then DELTA(1) = 1. If N = 2, see SLAED5 for detail. The vector DELTA contains the information necessary to construct the eigenvectors by SLAED3 and SLAED9.

RHO Input parameter.

RHO is REAL

The scalar in the symmetric updating formula.

DLAM Output parameter.

DLAM is REAL

The computed lambda_I, the I-th updated eigenvalue.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = 1, the updating process failed.

Related Information

For this routine in other precisions, please see *dlaed4*.

4.17.456 slaed5

This subroutine computes the I-th eigenvalue of a symmetric rank-one modification of a 2-by-2 diagonal matrix

```
diag( D )  +  RHO * Z * transpose(Z) .
```

The diagonal elements in the array D are assumed to satisfy

```
D(i) < D(j)  for  i < j .
```

We also assume RHO > 0 and that the Euclidean norm of the vector Z is one.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed5(I, D, Z, DELTA, RHO, DLAM)
```

C specification:

```
#include "armpl.h"

void slaed5_(const armpl_int_t *i, const float *d, const float *z,
             float *delta, const float *rho, float *dlam);
```

Parameters

I Input parameter.

I is INTEGER

The index of the eigenvalue to be computed. I = 1 or I = 2.

D Input parameter.

D is REAL

D is an array, dimension (2). The original eigenvalues. We assume D(1) < D(2).

Z Input parameter.

Z is REAL

Z is an array, dimension (2). The components of the updating vector.

DELTA Output parameter.

DELTA is REAL

DELTA is an array, dimension (2). The vector DELTA contains the information necessary to construct the eigenvectors.

RHO Input parameter.

RHO is REAL

The scalar in the symmetric updating formula.

DLAM Output parameter.

DLAM is REAL

The computed lambda_I, the I-th updated eigenvalue.

Related Information

For this routine in other precisions, please see *dlaed5*.

4.17.457 slaed6

slaed6 computes the positive or negative root (closest to the origin) of

```
z(1)        z(2)        z(3)
```

f(x) = rho + ——— + ———- + ———

```
d(1)-x      d(2)-x      d(3)-x
```

It is assumed that

```
 if ORGATI = .true. the root is between d(2) and d(3);
otherwise it is between d(1) and d(2)
```

This routine will be called by SLAED4 when necessary. In most cases, the root sought is the smallest in magnitude, though it might not be in some extremely rare situations.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed6(KNITER, ORGATI, RHO, D, Z, FINIT, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void slaed6_(const armpl_int_t *kniter, const armpl_int_t *orgati,
             const float *rho, const float *d, const float *z,
             const float *finit, float *tau, armpl_int_t *info);
```

Parameters

KNITER Input parameter.

KNITER is INTEGER

Refer to SLAED4 for its significance.

ORGATI Input parameter.

ORGATI is LOGICAL

If ORGATI is true, the needed root is between d(2) and d(3); otherwise it is between d(1) and d(2). See SLAED4 for further details.

RHO Input parameter.

RHO is REAL

Refer to the equation f(x) above.

D Input parameter.

D is REAL

D is an array, dimension (3). D satisfies d(1) < d(2) < d(3).

Z Input parameter.

Z is REAL

Z is an array, dimension (3). Each of the elements in z must be positive.

FINIT Input parameter.

FINIT is REAL

The value of f at 0. It is more accurate than the one evaluated inside this routine (if someone wants to do so).

TAU Output parameter.

TAU is REAL

The root of the equation f(x).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = 1, failure to converge

Related Information

For this routine in other precisions, please see *dlaed6*.

4.17.458 slaed7

slaed7 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and optionally eigenvectors of a dense symmetric matrix that has been reduced to tridiagonal form. SLAED1 handles the case in which all eigenvalues and eigenvectors of a symmetric tridiagonal matrix are desired.

```
T = Q(in) ( D(in) + RHO * Z*Z**T ) Q**T(in) = Q(out) * D(out) * Q**T(out)

where Z = Q**Tu, u is a vector of length N with ones in the
CUTPNT and CUTPNT + 1 th elements and zeros elsewhere.

The eigenvectors of the original matrix are stored in Q, and the
eigenvalues are in D.  The algorithm consists of three stages:

   The first stage consists of deflating the size of the problem
   when there are multiple eigenvalues or if there is a zero in
   the Z vector.  For each such occurrence the dimension of the
   secular equation problem is reduced by one.  This stage is
   performed by the routine SLAED8.

   The second stage consists of calculating the updated
   eigenvalues. This is done by finding the roots of the secular
   equation via the routine SLAED4 (as called by SLAED9).
   This routine also calculates the eigenvectors of the current
   problem.

   The final stage consists of computing the updated eigenvectors
   directly using the updated eigenvalues.  The eigenvectors for
   the current problem are multiplied with the eigenvectors from
   the overall problem.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed7(ICOMPQ, N, QSIZ, TLVLS, CURLVL, CURPBM, D, Q, LDQ, INDXQ,
                  RHO, CUTPNT, QSTORE, QPTR, PRMPTR, PERM, GIVPTR, GIVCOL,
                  GIVNUM, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slaed7_(const armpl_int_t *icompq, const armpl_int_t *n,
             const armpl_int_t *qsiz, const armpl_int_t *tlvls,
             const armpl_int_t *curlvl, const armpl_int_t *curpbm, float *d,
             float *q, const armpl_int_t *ldq, armpl_int_t *indxq,
             const float *rho, const armpl_int_t *cutpnt, float *qstore,
             armpl_int_t *qptr, const armpl_int_t *prmptr,
             const armpl_int_t *perm, const armpl_int_t *givptr,
             const armpl_int_t *givcol, const float *givnum, float *work,
             armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

= 0: Compute eigenvalues only. = 1: Compute eigenvectors of original dense symmetric matrix also. On entry, Q contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the orthogonal matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

TLVLS Input parameter.

TLVLS is INTEGER

The total number of merging levels in the overall divide and conquer tree.

CURLVL Input parameter.

CURLVL is INTEGER

The current level in the overall merge routine, 0 <= CURLVL <= TLVLS.

CURPBM Input parameter.

CURPBM is INTEGER

The current problem in the current level in the overall merge routine (counting from upper left to lower right).

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the eigenvalues of the rank-1-perturbed matrix. On exit, the eigenvalues of the repaired matrix.

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, the eigenvectors of the rank-1-perturbed matrix. On exit, the eigenvectors of the repaired tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

INDXQ Output parameter.

INDXQ is INTEGER array, dimension (N)

The permutation which will reintegrate the subproblem just solved back into sorted order, i.e., D(INDXQ(I = 1, N)) will be in ascending order.

RHO Input parameter.

RHO is REAL

The subdiagonal element used to create the rank-1 modification.

CUTPNT Input parameter.

CUTPNT is INTEGER

Contains the location of the last eigenvalue in the leading sub-matrix. min(1, N) <= CUTPNT <= N.

QSTORE Input and output parameter.

QSTORE is REAL

QSTORE is an array, dimension (N**2+1). Stores eigenvectors of submatrices encountered during divide and conquer, packed together. QPTR points to beginning of the submatrices.

QPTR Input and output parameter.

QPTR is INTEGER array, dimension (N+2)

List of indices pointing to beginning of submatrices stored in QSTORE. The submatrices are numbered starting at the bottom left of the divide and conquer tree, from left to right and bottom to top.

PRMPTR Input parameter.

PRMPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in PERM a level's permutation is stored. PRMPTR(i+1) - PRMPTR(i) indicates the size of the permutation and also the size of the full, non-deflated problem.

PERM Input parameter.

PERM is INTEGER array, dimension (N lg N)

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in GIVCOL a level's Givens rotations are stored. GIVPTR(i+1) - GIVPTR(i) indicates the number of Givens rotations.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (2, N lg N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Input parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (2, N lg N). Each number indicates the S value to be used in the corresponding Givens rotation.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N+2*QSIZ*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (4*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *claed7*, *dlaed7* and *zlaed7*.

4.17.459 slaed8

slaed8 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny element in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed8(ICOMPQ, K, N, QSIZ, D, Q, LDQ, INDXQ, RHO, CUTPNT, Z,
                  DLAMDA, Q2, LDQ2, W, PERM, GIVPTR, GIVCOL, GIVNUM, INDXP,
                  INDX, INFO)
```

C specification:

```
#include "armpl.h"

void slaed8_(const armpl_int_t *icompq, armpl_int_t *k, const armpl_int_t *n,
             const armpl_int_t *qsiz, float *d, float *q,
             const armpl_int_t *ldq, const armpl_int_t *indxq, float *rho,
             const armpl_int_t *cutpnt, const float *z, float *dlamda,
             float *q2, const armpl_int_t *ldq2, float *w, armpl_int_t *perm,
             armpl_int_t *givptr, armpl_int_t *givcol, float *givnum,
             armpl_int_t *indxp, armpl_int_t *indx, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

= 0: Compute eigenvalues only. = 1: Compute eigenvectors of original dense symmetric matrix also. On entry, Q contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

K Output parameter.

K is INTEGER

The number of non-deflated eigenvalues, and the order of the related secular equation.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the orthogonal matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the eigenvalues of the two submatrices to be combined. On exit, the trailing (N-K) updated eigenvalues (those which were deflated) sorted into increasing order.

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). If ICOMPQ = 0, Q is not referenced. Otherwise, on entry, Q contains the eigenvectors of the partially solved system which has been previously updated in matrix multiplies with other partially solved eigensystems. On exit, Q contains the trailing (N-K) updated eigenvectors (those which were deflated) in its last N-K columns.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

INDXQ Input parameter.

INDXQ is INTEGER array, dimension (N)

The permutation which separately sorts the two sub-problems in D into ascending order. Note that elements in the second half of this permutation must first have CUTPNT added to their values in order to be accurate.

RHO Input and output parameter.

RHO is REAL

On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined. On exit, RHO has been modified to the value required by SLAED3.

CUTPNT Input parameter.

CUTPNT is INTEGER

The location of the last eigenvalue in the leading sub-matrix. min(1, N) <= CUTPNT <= N.

Z Input parameter.

Z is REAL

Z is an array, dimension (N). On entry, Z contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). On exit, the contents of Z are destroyed by the updating process.

DLAMDA Output parameter.

DLAMDA is REAL

DLAMDA is an array, dimension (N). A copy of the first K eigenvalues which will be used by SLAED3 to form the secular equation.

Q2 Output parameter.

Q2 is REAL

Q2 is an array, dimension (LDQ2, N). If ICOMPQ = 0, Q2 is not referenced. Otherwise, a copy of the first K eigenvectors which will be used by SLAED7 in a matrix multiply (SGEMM) to update the new eigenvectors.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of the array Q2. LDQ2 >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). The first k values of the final deflation-altered z-vector and will be passed to SLAED3.

PERM Output parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Output parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem.

GIVCOL Output parameter.

GIVCOL is INTEGER array, dimension (2, N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Output parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (2, N). Each number indicates the S value to be used in the corresponding Givens rotation.

INDXP Output parameter.

INDXP is INTEGER array, dimension (N)

The permutation used to place deflated values of D at the end of the array. INDXP(1:K) points to the nondeflated D-values and INDXP(K+1:N) points to the deflated eigenvalues.

INDX Output parameter.

INDX is INTEGER array, dimension (N)

The permutation used to sort the contents of D into ascending order.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *claed8*, *dlaed8* and *zlaed8*.

4.17.460 slaed9

slaed9 finds the roots of the secular equation, as defined by the values in D, Z, and RHO, between KSTART and KSTOP. It makes the appropriate calls to SLAED4 and then stores the new matrix of eigenvectors for use in calculating the next level of Z vectors.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaed9(K, KSTART, KSTOP, N, D, Q, LDQ, RHO, DLAMDA, W, S, LDS,
                  INFO)
```

C specification:

```
#include "armpl.h"

void slaed9_(const armpl_int_t *k, const armpl_int_t *kstart,
             const armpl_int_t *kstop, const armpl_int_t *n, float *d,
             float *q, const armpl_int_t *ldq, const float *rho,
             const float *dlamda, const float *w, float *s,
             const armpl_int_t *lds, armpl_int_t *info);
```

Parameters

K Input parameter.

K is INTEGER

The number of terms in the rational function to be solved by SLAED4. K >= 0.

KSTART Input parameter.

KSTART is INTEGER

KSTOP Input parameter.

KSTOP is INTEGER

The updated eigenvalues Lambda(I), KSTART <= I <= KSTOP are to be computed. 1 <= KSTART <= KSTOP <= K.

N Input parameter.

N is INTEGER

The number of rows and columns in the Q matrix. N >= K (delation may result in N > K).

D Output parameter.

D is REAL

D is an array, dimension (N). D(I) contains the updated eigenvalues for KSTART <= I <= KSTOP.

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ, N) .

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

RHO Input parameter.

RHO is REAL

The value of the parameter in the rank one update equation. RHO >= 0 required.

DLAMDA Input parameter.

DLAMDA is REAL

DLAMDA is an array, dimension (K). The first K elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

W Input parameter.

W is REAL

W is an array, dimension (K). The first K elements of this array contain the components of the deflation-adjusted updating vector.

S Output parameter.

S is REAL

S is an array, dimension (LDS, K). Will contain the eigenvectors of the repaired matrix which will be stored for subsequent Z vector calculation and multiplied by the previously accumulated eigenvectors to update the system.

LDS Input parameter.

LDS is INTEGER

The leading dimension of S. LDS >= max(1, K).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *dlaed9*.

4.17.461 slaeda

slaeda computes the Z vector corresponding to the merge step in the CURLVLth step of the merge process with TLVLS steps for the CURPBMth problem.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaeda(N, TLVLS, CURLVL, CURPBM, PRMPTR, PERM, GIVPTR, GIVCOL,
                  GIVNUM, Q, QPTR, Z, ZTEMP, INFO)
```

C specification:

```
#include "armpl.h"

void slaeda_(const armpl_int_t *n, const armpl_int_t *tlvls,
             const armpl_int_t *curlvl, const armpl_int_t *curpbm,
             const armpl_int_t *prmptr, const armpl_int_t *perm,
             const armpl_int_t *givptr, const armpl_int_t *givcol,
             const float *givnum, const float *q, const armpl_int_t *qptr,
             float *z, float *ztemp, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

TLVLS Input parameter.

TLVLS is INTEGER

The total number of merging levels in the overall divide and conquer tree.

CURLVL Input parameter.

CURLVL is INTEGER

The current level in the overall merge routine, 0 <= curlvl <= tlvls.

CURPBM Input parameter.

CURPBM is INTEGER

The current problem in the current level in the overall merge routine (counting from upper left to lower right).

PRMPTR Input parameter.

PRMPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in PERM a level's permutation is stored. PRMPTR(i+1) - PRMPTR(i) indicates the size of the permutation and incidentally the size of the full, non-deflated problem.

PERM Input parameter.

PERM is INTEGER array, dimension (N lg N)

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in GIVCOL a level's Givens rotations are stored. GIVPTR(i+1) - GIVPTR(i) indicates the number of Givens rotations.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (2, N lg N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Input parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (2, N lg N). Each number indicates the S value to be used in the corresponding Givens rotation.

Q Input parameter.

Q is REAL

Q is an array, dimension (N**2). Contains the square eigenblocks from previous levels, the starting positions for blocks are given by QPTR.

QPTR Input parameter.

QPTR is INTEGER array, dimension (N+2)

Contains a list of pointers which indicate where in Q an eigenblock is stored. SQRT(QPTR(i+1) - QPTR(i)) indicates the size of the block.

Z Output parameter.

Z is REAL

Z is an array, dimension (N). On output this vector contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix).

ZTEMP Output parameter.

ZTEMP is REAL

ZTEMP is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dlaeda*.

4.17.462 slaein

`slaein` uses inverse iteration to find a right or left eigenvector corresponding to the eigenvalue (WR,WI) of a real upper Hessenberg matrix H.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaein(RIGHTV, NOINIT, N, H, LDH, WR, WI, VR, VI, B, LDB, WORK,
                  EPS3, SMLNUM, BIGNUM, INFO)
```

C specification:

```
#include "armpl.h"

void slaein_(const armpl_int_t *rightv, const armpl_int_t *noinit,
             const armpl_int_t *n, const float *h, const armpl_int_t *ldh,
             const float *wr, const float *wi, float *vr, float *vi, float *b,
             const armpl_int_t *ldb, float *work, const float *eps3,
             const float *smlnum, const float *bignum, armpl_int_t *info);
```

Parameters

RIGHTV Input parameter.

RIGHTV is LOGICAL

= .TRUE. : compute right eigenvector; = .FALSE.: compute left eigenvector.

NOINIT Input parameter.

NOINIT is LOGICAL

= .TRUE. : no initial vector supplied in (VR, VI). = .FALSE.: initial vector supplied in (VR, VI).

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

H Input parameter.

H is REAL

H is an array, dimension (LDH, N). The upper Hessenberg matrix H.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

WR Input parameter.

WR is REAL

WI Input parameter.

WI is REAL

The real and imaginary parts of the eigenvalue of H whose corresponding right or left eigenvector is to be computed.

VR Input and output parameter.

VR is REAL

VR is an array, dimension (N) .

VI Input and output parameter.

VI is REAL

VI is an array, dimension (N). On entry, if NOINIT = .FALSE. and WI = 0.0, VR must contain a real starting vector for inverse iteration using the real eigenvalue WR; if NOINIT = .FALSE. and WI.ne.0.0, VR and VI must contain the real and imaginary parts of a complex starting vector for inverse iteration using the complex eigenvalue (WR, WI); otherwise VR and VI need not be set. On exit, if WI = 0.0 (real eigenvalue), VR contains the computed real eigenvector; if WI.ne.0.0 (complex eigenvalue), VR and VI contain the real and imaginary parts of the computed complex eigenvector. The eigenvector is normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x| + |y|. VI is not referenced if WI = 0.0.

B Output parameter.

B is REAL

B is an array, dimension (LDB, N) .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= N+1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

EPS3 Input parameter.

EPS3 is REAL

A small machine-dependent value which is used to perturb close eigenvalues, and to replace zero pivots.

SMLNUM Input parameter.

SMLNUM is REAL

A machine-dependent value close to the underflow threshold.

BIGNUM Input parameter.

BIGNUM is REAL

A machine-dependent value close to the overflow threshold.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit = 1: inverse iteration did not converge; VR is set to the last iterate, and so is VI if WI.ne.0.0.

4.17.463 slaev2

slaev2 computes the eigendecomposition of a 2-by-2 symmetric matrix

```
[  A   B  ]
[  B   C  ].
```

On return, RT1 is the eigenvalue of larger absolute value, RT2 is the eigenvalue of smaller absolute value, and (CS1,SN1) is the unit right eigenvector for RT1, giving the decomposition

```
[ CS1  SN1 ] [  A   B  ] [ CS1 -SN1 ]  =  [ RT1  0  ]
[-SN1  CS1 ] [  B   C  ] [ SN1  CS1 ]     [  0  RT2 ].
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slaev2(A, B, C, RT1, RT2, CS1, SN1)
```

C specification:

```
#include "armpl.h"

void slaev2_(const float *a, const float *b, const float *c, float *rt1,
             float *rt2, float *cs1, float *sn1);
```

Parameters

A Input parameter.

A is REAL

The (1,1) element of the 2-by-2 matrix.

B Input parameter.

B is REAL

The (1,2) element and the conjugate of the (2,1) element of the 2-by-2 matrix.

C Input parameter.

C is REAL

The (2,2) element of the 2-by-2 matrix.

RT1 Output parameter.

RT1 is REAL

The eigenvalue of larger absolute value.

RT2 Output parameter.

RT2 is REAL

The eigenvalue of smaller absolute value.

CS1 Output parameter.

CS1 is REAL

SN1 Output parameter.

SN1 is REAL

The vector (CS1, SN1) is a unit right eigenvector for RT1.

Related Information

For this routine in other precisions, please see *claev2*, *dlaev2* and *zlaev2*.

4.17.464 slaexc

slaexc swaps adjacent diagonal blocks T11 and T22 of order 1 or 2 in an upper quasi-triangular matrix T by an orthogonal similarity transformation.

T must be in Schur canonical form, that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elemnts equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaexc(WANTQ, N, T, LDT, Q, LDQ, J1, N1, N2, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void slaexc_(const armpl_int_t *wantq, const armpl_int_t *n, float *t,
             const armpl_int_t *ldt, float *q, const armpl_int_t *ldq,
             const armpl_int_t *j1, const armpl_int_t *n1,
             const armpl_int_t *n2, float *work, armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

WANTQ is LOGICAL

= .TRUE. : accumulate the transformation in the matrix Q; = .FALSE.: do not accumulate the transformation.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is REAL

T is an array, dimension (LDT, N). On entry, the upper quasi-triangular matrix T, in Schur canonical form. On exit, the updated matrix T, again in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if WANTQ is .TRUE., the orthogonal matrix Q. On exit, if WANTQ is .TRUE., the updated matrix Q. If WANTQ is .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; and if WANTQ is .TRUE., LDQ >= N.

J1 Input parameter.

J1 is INTEGER

The index of the first row of the first block T11.

N1 Input parameter.

N1 is INTEGER

The order of the first block T11. N1 = 0, 1 or 2.

N2 Input parameter.

N2 is INTEGER

The order of the second block T22. N2 = 0, 1 or 2.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit = 1: the transformed matrix T would be too far from Schur form; the blocks are not swapped and T and Q are unchanged.

Related Information

For this routine in other precisions, please see *dlaexc*.

4.17.465 slag2

slag2 computes the eigenvalues of a 2 x 2 generalized eigenvalue problem A - w B, with scaling as necessary to avoid over-/underflow.

The scaling factor "s" results in a modified eigenvalue equation

```
s A - w B
```

where s is a non-negative scaling factor chosen so that w, w B, and s A do not overflow and, if possible, do not underflow, either.

Syntax

Fortran specification:

```
use armpl_library

subroutine slag2(A, LDA, B, LDB, SAFMIN, SCALE1, SCALE2, WR1, WR2, WI)
```

C specification:

```
#include "armpl.h"

void slag2_(const float *a, const armpl_int_t *lda, const float *b,
            const armpl_int_t *ldb, const float *safmin, float *scale1,
            float *scale2, float *wr1, float *wr2, float *wi);
```

Parameters

A Input parameter.

A is REAL

A is an array, dimension (LDA, 2). On entry, the 2 x 2 matrix A. It is assumed that its 1-norm is less than 1/SAFMIN. Entries less than sqrt(SAFMIN)*norm(A) are subject to being treated as zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= 2.

B Input parameter.

B is REAL

B is an array, dimension (LDB, 2). On entry, the 2 x 2 upper triangular matrix B. It is assumed that the one-norm of B is less than 1/SAFMIN. The diagonals should be at least sqrt(SAFMIN) times the largest element of B (in absolute value); if a diagonal is smaller than that, then +/- sqrt(SAFMIN) will be used instead of that diagonal.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= 2.

SAFMIN Input parameter.

SAFMIN is REAL

The smallest positive number s.t. 1/SAFMIN does not overflow. (This should always be SLAMCH('S') – it is an argument in order to avoid having to call SLAMCH frequently.)

SCALE1 Output parameter.

SCALE1 is REAL

A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the first eigenvalue. If the eigenvalues are complex, then the eigenvalues are (WR1 +/- WI i) / SCALE1 (which may lie outside the exponent range of the machine), SCALE1=SCALE2, and SCALE1 will always be positive. If the eigenvalues are real, then the first (real) eigenvalue is WR1 / SCALE1 , but this may overflow or underflow, and in fact, SCALE1 may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

SCALE2 Output parameter.

SCALE2 is REAL

A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the second eigenvalue. If the eigenvalues are complex, then SCALE2=SCALE1. If the eigenvalues are real, then the second (real) eigenvalue is WR2 / SCALE2 , but this may overflow or underflow, and in fact, SCALE2 may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

WR1 Output parameter.

WR1 is REAL

If the eigenvalue is real, then WR1 is SCALE1 times the eigenvalue closest to the (2,2) element of A B**(-1). If the eigenvalue is complex, then WR1=WR2 is SCALE1 times the real part of the eigenvalues.

WR2 Output parameter.

WR2 is REAL

If the eigenvalue is real, then WR2 is SCALE2 times the other eigenvalue. If the eigenvalue is complex, then WR1=WR2 is SCALE1 times the real part of the eigenvalues.

WI Output parameter.

WI is REAL

If the eigenvalue is real, then WI is zero. If the eigenvalue is complex, then WI is SCALE1 times the imaginary part of the eigenvalues. WI will always be non-negative.

Related Information

For this routine in other precisions, please see *dlag2*.

4.17.466 slag2d

slag2d converts a SINGLE PRECISION matrix, SA, to a DOUBLE PRECISION matrix, A.

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is an auxiliary routine so there is no argument checking.

Syntax

Fortran specification:

```
use armpl_library

subroutine slag2d(M, N, SA, LDSA, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void slag2d_(const armpl_int_t *m, const armpl_int_t *n, const float *sa,
             const armpl_int_t *ldsa, double *a, const armpl_int_t *lda,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of lines of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

SA Input parameter.

SA is REAL

SA is an array, dimension (LDSA, N). On entry, the M-by-N coefficient matrix SA.

LDSA Input parameter.

LDSA is INTEGER

The leading dimension of the array SA. LDSA >= max(1, M).

A Output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On exit, the M-by-N coefficient matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

Related Information

It also exists with a native C interface as *LAPACKE_slag2d*.

4.17.467 slags2

slags2 computes 2-by-2 orthogonal matrices U, V and Q, such that if (UPPER) then

```
U**T *A*Q = U**T *( A1 A2 )*Q = ( x  0  )
                  ( 0  A3 )     ( x  x  )
```

and

```
V**T*B*Q = V**T *( B1 B2 )*Q = ( x  0  )
                 ( 0  B3 )     ( x  x  )
```

or if (.NOT.UPPER) then

```
U**T *A*Q = U**T *( A1 0  )*Q = ( x  x  )
                  ( A2 A3 )     ( 0  x  )
```

and

```
V**T*B*Q = V**T*( B1 0  )*Q = ( x  x  )
                ( B2 B3 )     ( 0  x  )
```

The rows of the transformed A and B are parallel, where

```
U = (  CSU  SNU ), V = (  CSV SNV ), Q = (  CSQ   SNQ )
   ( -SNU  CSU )       ( -SNV CSV )       ( -SNQ   CSQ )
```

Z^T denotes the transpose of Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine slags2(UPPER, A1, A2, A3, B1, B2, B3, CSU, SNU, CSV, SNV, CSQ,
                  SNQ)
```

C specification:

```
#include "armpl.h"

void slags2_(const armpl_int_t *upper, const float *a1, const float *a2,
             const float *a3, const float *b1, const float *b2,
             const float *b3, float *csu, float *snu, float *csv, float *snv,
             float *csq, float *snq);
```

Parameters

UPPER Input parameter.

UPPER is LOGICAL

= .TRUE.: the input matrices A and B are upper triangular. = .FALSE.: the input matrices A and B are lower triangular.

A1 Input parameter.

A1 is REAL

A2 Input parameter.

A2 is REAL

A3 Input parameter.

A3 is REAL

On entry, A1, A2 and A3 are elements of the input 2-by-2 upper (lower) triangular matrix A.

B1 Input parameter.

B1 is REAL

B2 Input parameter.

B2 is REAL

B3 Input parameter.

B3 is REAL

On entry, B1, B2 and B3 are elements of the input 2-by-2 upper (lower) triangular matrix B.

CSU Output parameter.

CSU is REAL

SNU Output parameter.

SNU is REAL

The desired orthogonal matrix U.

CSV Output parameter.

CSV is REAL

SNV Output parameter.

SNV is REAL

The desired orthogonal matrix V.

CSQ Output parameter.

CSQ is REAL

SNQ Output parameter.

SNQ is REAL

The desired orthogonal matrix Q.

Related Information

For this routine in other precisions, please see *clags2*, *dlags2* and *zlags2*.

4.17.468 slagtf

slagtf factorizes the matrix (T - lambda*I), where T is an n by n tridiagonal matrix and lambda is a scalar, as

```
T - lambda*I = PLU,
```

where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column.

The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling.

The parameter LAMBDA is included in the routine so that slagtf may be used, in conjunction with SLAGTS, to obtain eigenvectors of T by inverse iteration.

Syntax

Fortran specification:

```
use armpl_library

subroutine slagtf(N, A, LAMBDA, B, C, TOL, D, IN, INFO)
```

C specification:

```
#include "armpl.h"

void slagtf_(const armpl_int_t *n, float *a, const float *lambda, float *b,
             float *c, const float *tol, float *d, armpl_int_t *in,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix T.

A Input and output parameter.

A is REAL

A is an array, dimension (N). On entry, A must contain the diagonal elements of T.

On exit, A is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T.

LAMBDA Input parameter.

LAMBDA is REAL

On entry, the scalar lambda.

B Input and output parameter.

B is REAL

B is an array, dimension (N-1). On entry, B must contain the (n-1) super-diagonal elements of T.

On exit, B is overwritten by the (n-1) super-diagonal elements of the matrix U of the factorization of T.

C Input and output parameter.

C is REAL

C is an array, dimension (N-1). On entry, C must contain the (n-1) sub-diagonal elements of T.

On exit, C is overwritten by the (n-1) sub-diagonal elements of the matrix L of the factorization of T.

TOL Input parameter.

TOL is REAL

On entry, a relative tolerance used to indicate whether or not the matrix (T - lambda*I) is nearly singular. TOL should normally be chose as approximately the largest relative error in the elements of T. For example, if the elements of T are correct to about 4 significant figures, then TOL should be set to about 5*10**(-4). If TOL is supplied as less than eps, where eps is the relative machine precision, then the value eps is used in place of TOL.

D Output parameter.

D is REAL

D is an array, dimension (N-2). On exit, D is overwritten by the (n-2) second super-diagonal elements of the matrix U of the factorization of T.

IN Output parameter.

IN is INTEGER array, dimension (N)

On exit, IN contains details of the permutation matrix P. If an interchange occurred at the kth step of the elimination, then IN(k) = 1, otherwise IN(k) = 0. The element IN(n) returns the smallest positive integer j such that

abs(u(j,j)).le. norm((T - lambda*I)(j))*TOL,

where norm(A(j)) denotes the sum of the absolute values of the jth row of the matrix A. If no such j exists then IN(n) is returned as zero. If IN(n) is returned as positive, then a diagonal element of U is small, indicating that (T - lambda*I) is singular or nearly singular,

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit .lt. 0: if INFO = -k, the kth argument had an illegal value

Related Information

For this routine in other precisions, please see *dlagtf*.

4.17.469 slagtm

slagtm performs a matrix-vector product of the form

```
B := alpha * A * X + beta * B
```

where A is a tridiagonal matrix of order N, B and X are N by NRHS matrices, and alpha and beta are real scalars, each of which may be 0., 1., or -1.

Syntax

Fortran specification:

```
use armpl_library

subroutine slagtm(TRANS, N, NRHS, ALPHA, DL, D, DU, X, LDX, BETA, B, LDB)
```

C specification:

```
#include "armpl.h"

void slagtm_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *alpha, const float *dl, const float *d,
             const float *du, const float *x, const armpl_int_t *ldx,
             const float *beta, float *b, const armpl_int_t *ldb, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': No transpose, B := alpha * A * X + beta * B = 'T': Transpose, B := alpha * A'* X + beta * B = 'C': Conjugate transpose = Transpose

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices X and B.

ALPHA Input parameter.

ALPHA is REAL

The scalar alpha. ALPHA must be 0., 1., or -1.; otherwise, it is assumed to be 0.

DL Input parameter.

DL is REAL

DL is an array, dimension (N-1). The (n-1) sub-diagonal elements of T.

D Input parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of T.

DU Input parameter.

DU is REAL

DU is an array, dimension (N-1). The (n-1) super-diagonal elements of T.

X Input parameter.

X is REAL

X is an array, dimension (LDX, NRHS). The N by NRHS matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(N,1).

BETA Input parameter.

BETA is REAL

The scalar beta. BETA must be 0., 1., or -1.; otherwise, it is assumed to be 1.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the N by NRHS matrix B. On exit, B is overwritten by the matrix expression B := alpha * A * X + beta * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(N,1).

Related Information

For this routine in other precisions, please see *clagtm*, *dlagtm* and *zlagtm*.

4.17.470 slagts

slagts may be used to solve one of the systems of equations

```
(T - lambda*I)*x = y   or   (T - lambda*I)**T*x = y,
```

where T is an n by n tridiagonal matrix, for x, following the factorization of (T - lambda*I) as

```
(T - lambda*I) = P*L*U ,
```

by routine SLAGTF. The choice of equation to be solved is controlled by the argument JOB, and in each case there is an option to perturb zero or very small diagonal elements of U, this option being intended for use in applications such as inverse iteration.

Syntax

Fortran specification:

```
use armpl_library

subroutine slagts(JOB, N, A, B, C, D, IN, Y, TOL, INFO)
```

C specification:

```
#include "armpl.h"

void slagts_(const armpl_int_t *job, const armpl_int_t *n, const float *a,
             const float *b, const float *c, const float *d,
             const armpl_int_t *in, float *y, float *tol, armpl_int_t *info);
```

Parameters

JOB Input parameter.

JOB is INTEGER

Specifies the job to be performed by SLAGTS as follows: = 1: The equations (T - lambda*I)x = y are to be solved, but diagonal elements of U are not to be perturbed. = -1: The equations (T - lambda*I)x = y are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument TOL below. = 2: The equations $(T - lambda*I)^T$ x = y are to be solved, but diagonal elements of U are not to be perturbed. = -2: The equations $(T - lambda*I)^T$ x = y are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument TOL below.

N Input parameter.

N is INTEGER

The order of the matrix T.

A Input parameter.

A is REAL

A is an array, dimension (N). On entry, A must contain the diagonal elements of U as returned from SLAGTF.

B Input parameter.

B is REAL

B is an array, dimension (N-1). On entry, B must contain the first super-diagonal elements of U as returned from SLAGTF.

C Input parameter.

C is REAL

C is an array, dimension (N-1). On entry, C must contain the sub-diagonal elements of L as returned from SLAGTF.

D Input parameter.

D is REAL

D is an array, dimension (N-2). On entry, D must contain the second super-diagonal elements of U as returned from SLAGTF.

IN Input parameter.

IN is INTEGER array, dimension (N)

On entry, IN must contain details of the matrix P as returned from SLAGTF.

Y Input and output parameter.

Y is REAL

Y is an array, dimension (N). On entry, the right hand side vector y. On exit, Y is overwritten by the solution vector x.

TOL Input and output parameter.

TOL is REAL

On entry, with JOB .lt. 0, TOL should be the minimum perturbation to be made to very small diagonal elements of U. TOL should normally be chosen as about eps*norm(U), where eps is the relative machine precision, but if TOL is supplied as non-positive, then it is reset to eps*max(abs(u(i,j))). If JOB .gt. 0 then TOL is not referenced.

On exit, TOL is changed as described above, only if TOL is non-positive on entry. Otherwise TOL is unchanged.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit .lt. 0: if INFO = -i, the i-th argument had an illegal value .gt. 0: overflow would occur when computing the INFO(th) element of the solution vector x. This can only occur when JOB is supplied as positive and either means that a diagonal element of U is very small, or that the elements of the right-hand side vector y are very large.

Related Information

For this routine in other precisions, please see *dlagts*.

4.17.471 slagv2

slagv2 computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A,B) where B is upper triangular. This routine computes orthogonal (rotation) matrices given by CSL, SNL and CSR, SNR such that

1) if the pencil (A,B) has two real eigenvalues (include 0/0 or 1/0

```
 types), then

[ a11 a12 ] := [  CSL  SNL ] [ a11 a12 ] [  CSR -SNR ]
[  0  a22 ]    [ -SNL  CSL ] [ a21 a22 ] [  SNR  CSR ]

[ b11 b12 ] := [  CSL  SNL ] [ b11 b12 ] [  CSR -SNR ]
[  0  b22 ]    [ -SNL  CSL ] [  0  b22 ] [  SNR  CSR ],
```

2) if the pencil (A,B) has a pair of complex conjugate eigenvalues,

```
 then

[ a11 a12 ] := [  CSL  SNL ] [ a11 a12 ] [  CSR -SNR ]
[ a21 a22 ]    [ -SNL  CSL ] [ a21 a22 ] [  SNR  CSR ]

[ b11  0  ] := [  CSL  SNL ] [ b11 b12 ] [  CSR -SNR ]
[  0  b22 ]    [ -SNL  CSL ] [  0  b22 ] [  SNR  CSR ]

where b11 >= b22 > 0.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slagv2(A, LDA, B, LDB, ALPHAR, ALPHAI, BETA, CSL, SNL, CSR, SNR)
```

C specification:

```
#include "armpl.h"

void slagv2_(float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, float *alphar, float *alphai,
             float *beta, float *csl, float *snl, float *csr, float *snr);
```

Parameters

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, 2). On entry, the 2 x 2 matrix A. On exit, A is overwritten by the ''A-part" of the generalized Schur form.

LDA Input parameter.

LDA is INTEGER

THe leading dimension of the array A. LDA >= 2.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, 2). On entry, the upper triangular 2 x 2 matrix B. On exit, B is overwritten by the ''B-part" of the generalized Schur form.

LDB Input parameter.

LDB is INTEGER

THe leading dimension of the array B. LDB >= 2.

ALPHAR Output parameter.

ALPHAR is REAL

ALPHAR is an array, dimension (2) .

ALPHAI Output parameter.

ALPHAI is REAL

ALPHAI is an array, dimension (2) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (2). (ALPHAR(k)+i*ALPHAI(k))/BETA(k) are the eigenvalues of the pencil (A, B), k=1,2, i = sqrt(-1). Note that BETA(k) may be zero.

CSL Output parameter.

CSL is REAL

The cosine of the left rotation matrix.

SNL Output parameter.

SNL is REAL

The sine of the left rotation matrix.

CSR Output parameter.

CSR is REAL

The cosine of the right rotation matrix.

SNR Output parameter.

SNR is REAL

The sine of the right rotation matrix.

Related Information

4.17.472 slahqr

```
SLAHQR is an auxiliary routine called by SHSEQR to update the
   eigenvalues and Schur decomposition already computed by SHSEQR, by
   dealing with the Hessenberg submatrix in rows and columns ILO to
   IHI.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slahqr(WANTT, WANTZ, N, ILO, IHI, H, LDH, WR, WI, ILOZ, IHIZ, Z,
                  LDZ, INFO)
```

C specification:

```
#include "armpl.h"

void slahqr_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, float *h, const armpl_int_t *ldh,
             float *wr, float *wi, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, float *z, const armpl_int_t *ldz,
             armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper quasi-triangular in rows and columns IHI+1:N, and that H(ILO,ILO-1) = 0 (unless ILO = 1). SLAHQR works primarily with the Hessenberg submatrix in rows and columns ILO to IHI, but applies transformations to all of H if WANTT is .TRUE.. 1 <= ILO <= max(1, IHI); IHI <= N.

H Input and output parameter.

H is REAL

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO is zero and if WANTT is .TRUE., H is upper quasi-triangular in rows and columns ILO:IHI, with any 2-by-2 diagonal blocks in standard form. If INFO is zero and WANTT is .FALSE., the contents of H are unspecified on exit. The output state of H if INFO is nonzero is given below under the description of INFO.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

WR Output parameter.

WR is REAL

WR is an array, dimension (N) .

WI Output parameter.

WI is REAL

WI is an array, dimension (N). The real and imaginary parts, respectively, of the computed eigenvalues ILO to IHI are stored in the corresponding elements of WR and WI. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with WI(i) > 0 and WI(i+1) < 0. If WANTT is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with WR(i) = H(i,i), and, if H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) = sqrt(H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 <= ILOZ <= ILO; IHI <= IHIZ <= N.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If WANTZ is .TRUE., on entry Z must contain the current matrix Z of transformations accumulated by SHSEQR, and on exit Z has been updated; transformations are applied only to the submatrix Z(ILOZ:IHIZ,ILO:IHI). If WANTZ is .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: If INFO = i, SLAHQR failed to compute all the eigenvalues ILO to IHI in a total of 30 iterations per eigenvalue; elements i+1:ihi of WR and WI contain those eigenvalues which have been successfully computed.

If INFO .GT. 0 and WANTT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO thorugh INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit (*) (initial value of H)*U = U*(final value of H) where U is an orthognal matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit (final value of Z) = (initial value of Z)*U where U is the orthogonal matrix in (*) (regardless of the value of WANTT.)

Related Information

4.17.473 slahr2

slahr2 reduces the first NB columns of A real general n-BY-(n-k+1) matrix A so that elements below the k-th subdiagonal are zero. The reduction is performed by an orthogonal similarity transformation Q^T * A * Q. The routine returns the matrices V and T which determine Q as a block reflector I - V*T*V^T , and also the matrix Y = A * V * T.

This is an auxiliary routine called by SGEHRD.

Syntax

Fortran specification:

```
use armpl_library

subroutine slahr2(N, K, NB, A, LDA, TAU, T, LDT, Y, LDY)
```

C specification:

```
#include "armpl.h"

void slahr2_(const armpl_int_t *n, const armpl_int_t *k,
             const armpl_int_t *nb, float *a, const armpl_int_t *lda,
             float *tau, float *t, const armpl_int_t *ldt, float *y,
             const armpl_int_t *ldy);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A.

K Input parameter.

K is INTEGER

The offset for the reduction. Elements below the k-th subdiagonal in the first NB columns are reduced to zero. K < N.

NB Input parameter.

NB is INTEGER

The number of columns to be reduced.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA,N-K+1). On entry, the n-by-(n-k+1) general matrix A. On exit, the elements on and above the k-th subdiagonal in the first NB columns are overwritten with the corresponding elements of the reduced matrix; the elements below the k-th subdiagonal, with the array TAU, represent the matrix Q as a product of elementary reflectors. The other columns of A are unchanged. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (NB). The scalar factors of the elementary reflectors. See Further Details.

T Output parameter.

T is REAL

T is an array, dimension (LDT, NB). The upper triangular matrix T.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

Y Output parameter.

Y is REAL

Y is an array, dimension (LDY, NB). The n-by-nb matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= N.

Related Information

4.17.474 slaic1

slaic1 applies one step of incremental condition estimation in its simplest version:

Let x, twonorm(x) = 1, be an approximate singular vector of an j-by-j lower triangular matrix L, such that

```
twonorm(L*x) = sest
```

Then slaic1 computes sestpr, s, c such that the vector

```
       [ s*x ]
xhat = [  c  ]
```

is an approximate singular vector of

```
       [ L       0    ]
Lhat = [ w**T gamma ]
```

in the sense that

```
twonorm(Lhat*xhat) = sestpr.
```

Depending on JOB, an estimate for the largest or smallest singular value is computed.

Note that [s c]^T and sestpr**2 is an eigenpair of the system

```
diag(sest*sest, 0) + [alpha  gamma] * [ alpha ]
                                      [ gamma ]
```

where alpha = x^T *w.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaic1(JOB, J, X, SEST, W, GAMMA, SESTPR, S, C)
```

C specification:

```
#include "armpl.h"

void slaic1_(const armpl_int_t *job, const armpl_int_t *j, const float *x,
             const float *sest, const float *w, const float *gamma,
             float *sestpr, float *s, float *c);
```

Parameters

JOB Input parameter.

JOB is INTEGER

= 1: an estimate for the largest singular value is computed. = 2: an estimate for the smallest singular value is computed.

J Input parameter.

J is INTEGER

Length of X and W

X Input parameter.

X is REAL

X is an array, dimension (J). The j-vector x.

SEST Input parameter.

SEST is REAL

Estimated singular value of j by j matrix L

W Input parameter.

W is REAL

W is an array, dimension (J). The j-vector w.

GAMMA Input parameter.

GAMMA is REAL

The diagonal element gamma.

SESTPR Output parameter.

SESTPR is REAL

Estimated singular value of (j+1) by (j+1) matrix Lhat.

S Output parameter.

S is REAL

Sine needed in forming xhat.

C Output parameter.

C is REAL

Cosine needed in forming xhat.

Related Information

For this routine in other precisions, please see *claic1*, *dlaic1* and *zlaic1*.

4.17.475 slaisnan

This routine is not for general use. It exists solely to avoid over-optimization in SISNAN.

SLAISNAN checks for NaNs by comparing its two arguments for inequality. NaN is the only floating-point value where NaN != NaN returns .TRUE. To check for NaNs, pass the same variable as both arguments.

A compiler must assume that the two arguments are not the same variable, and the test will not be optimized away. Interprocedural or whole-program optimization may delete this test. The ISNAN functions will be replaced by the correct Fortran 03 intrinsic once the intrinsic is widely available.

Syntax

Fortran specification:

```
use armpl_library

logical function slaisnan(SIN1, SIN2)
```

C specification:

```
#include "armpl.h"

armpl_int_t slaisnan_(const float *sin1, const float *sin2);
```

Parameters

SIN1 Input parameter.

SIN1 is REAL

SIN2 Input parameter.

SIN2 is REAL

Two numbers to compare for inequality.

Related Information

For this routine in other precisions, please see *dlaisnan*.

4.17.476 slaln2

`slaln2` solves a system of the form (ca A - w D) X = s B or (ca A^T - w D) X = s B with possible scaling ("s") and perturbation of A. (A^T means A-transpose.)

A is an NA x NA real matrix, ca is a real scalar, D is an NA x NA real diagonal matrix, w is a real or complex value, and X and B are NA x 1 matrices – real if w is real, complex if w is complex. NA may be 1 or 2.

If w is complex, X and B are represented as NA x 2 matrices, the first column of each being the real part and the second being the imaginary part.

"s" is a scaling factor (.LE. 1), computed by `slaln2`, which is so chosen that X can be computed without overflow. X is further scaled if necessary to assure that norm(ca A - w D)*norm(X) is less than overflow.

If both singular values of (ca A - w D) are less than SMIN, SMIN*identity will be used instead of (ca A - w D). If only one singular value is less than SMIN, one element of (ca A - w D) will be perturbed enough to make the smallest singular value roughly SMIN. If both singular values are at least SMIN, (ca A - w D) will not be perturbed. In any case, the perturbation will be at most some small multiple of max(SMIN, ulp*norm(ca A - w D)). The singular values are computed by infinity-norm approximations, and thus will only be correct to a factor of 2 or so.

Note: all input quantities are assumed to be smaller than overflow by a reasonable factor. (See BIGNUM.)

Syntax

Fortran specification:

```
use armpl_library

subroutine slaln2(LTRANS, NA, NW, SMIN, CA, A, LDA, D1, D2, B, LDB, WR, WI, X,
                  LDX, SCALE, XNORM, INFO)
```

C specification:

```
#include "armpl.h"

void slaln2_(const armpl_int_t *ltrans, const armpl_int_t *na,
             const armpl_int_t *nw, const float *smin, const float *ca,
             const float *a, const armpl_int_t *lda, const float *d1,
             const float *d2, const float *b, const armpl_int_t *ldb,
             const float *wr, const float *wi, float *x,
             const armpl_int_t *ldx, float *scale, float *xnorm,
             armpl_int_t *info);
```

Parameters

LTRANS Input parameter.

LTRANS is LOGICAL

=.TRUE.: A-transpose will be used. =.FALSE.: A will be used (not transposed.)

NA Input parameter.

NA is INTEGER

The size of the matrix A. It may (only) be 1 or 2.

NW Input parameter.

NW is INTEGER

1 if "w" is real, 2 if "w" is complex. It may only be 1 or 2.

SMIN Input parameter.

SMIN is REAL

The desired lower bound on the singular values of A. This should be a safe distance away from underflow or overflow, say, between (underflow/machine precision) and (machine precision * overflow). (See BIGNUM and ULP.)

CA Input parameter.

CA is REAL

The coefficient c, which A is multiplied by.

A Input parameter.

A is REAL

A is an array, dimension (LDA, NA). The NA x NA matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. It must be at least NA.

D1 Input parameter.

D1 is REAL

The 1,1 element in the diagonal matrix D.

D2 Input parameter.

D2 is REAL

The 2,2 element in the diagonal matrix D. Not used if NA=1.

B Input parameter.

B is REAL

B is an array, dimension (LDB, NW). The NA x NW matrix B (right-hand side). If NW=2 (“w” is complex), column 1 contains the real part of B and column 2 contains the imaginary part.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. It must be at least NA.

WR Input parameter.

WR is REAL

The real part of the scalar “w”.

WI Input parameter.

WI is REAL

The imaginary part of the scalar “w”. Not used if NW=1.

X Output parameter.

X is REAL

X is an array, dimension (LDX, NW). The NA x NW matrix X (unknowns), as computed by SLALN2. If NW=2 (“w” is complex), on exit, column 1 will contain the real part of X and column 2 will contain the imaginary part.

LDX Input parameter.

LDX is INTEGER

The leading dimension of X. It must be at least NA.

SCALE Output parameter.

SCALE is REAL

The scale factor that B must be multiplied by to insure that overflow does not occur when computing X. Thus, (ca A - w D) X will be SCALE*B, not B (ignoring perturbations of A.) It will be at most 1.

XNORM Output parameter.

XNORM is REAL

The infinity-norm of X, when X is regarded as an NA x NW real matrix.

INFO Output parameter.

INFO is INTEGER

An error flag. It will be set to zero if no error occurs, a negative number if an argument is in error, or a positive number if ca A - w D had to be perturbed. The possible values are: = 0: No error occurred, and (ca A - w D) did not have to be perturbed. = 1: (ca A - w D) had to be perturbed to make its smallest (or only) singular value greater than SMIN. NOTE: In the interests of speed, this routine does not check the inputs for errors.

Related Information

For this routine in other precisions, please see *dlaln2*.

4.17.477 slals0

slals0 applies back the multiplying factors of either the left or the right singular vector matrix of a diagonal matrix appended by a row to the right hand side matrix B in solving the least squares problem using the divide-and-conquer SVD approach.

For the left singular vector matrix, three types of orthogonal matrices are involved:

(1L) Givens rotations: the number of such rotations is GIVPTR; the

```
pairs of columns/rows they were applied to are stored in GIVCOL;
and the C- and S-values of these rotations are stored in GIVNUM.
```

(2L) Permutation. The (NL+1)-st row of B is to be moved to the first

```
row, and for J=2:N, PERM(J)-th row of B is to be moved to the
J-th row.
```

(3L) The left singular vector matrix of the remaining matrix.

For the right singular vector matrix, four types of orthogonal matrices are involved:

(1R) The right singular vector matrix of the remaining matrix.

(2R) If SQRE = 1, one extra Givens rotation to generate the right

```
null space.
```

(3R) The inverse transformation of (2L).

(4R) The inverse transformation of (1L).

Syntax

Fortran specification:

```
use armpl_library

subroutine slals0(ICOMPQ, NL, NR, SQRE, NRHS, B, LDB, BX, LDBX, PERM, GIVPTR,
                  GIVCOL, LDGCOL, GIVNUM, LDGNUM, POLES, DIFL, DIFR, Z, K, C,
                  S, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void slals0_(const armpl_int_t *icompq, const armpl_int_t *nl,
             const armpl_int_t *nr, const armpl_int_t *sqre,
             const armpl_int_t *nrhs, const float *b, const armpl_int_t *ldb,
             float *bx, const armpl_int_t *ldbx, const armpl_int_t *perm,
             const armpl_int_t *givptr, const armpl_int_t *givcol,
             const armpl_int_t *ldgcol, const float *givnum,
             const armpl_int_t *ldgnum, const float *poles, const float *difl,
             const float *difr, const float *z, const armpl_int_t *k,
             const float *c, const float *s, float *work, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in factored form: = 0: Left singular vector matrix. = 1: Right singular vector matrix.

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has row dimension N = NL + NR + 1, and column dimension M = N + SQRE.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B and BX. NRHS must be at least 1.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem in rows 1 through M. On output, B contains the solution X in rows 1 through N.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB must be at least max(1,MAX(M, N)).

BX Output parameter.

BX is REAL

BX is an array, dimension (LDBX, NRHS) .

LDBX Input parameter.

LDBX is INTEGER

The leading dimension of BX.

PERM Input parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) applied to the two blocks.

GIVPTR Input parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2)

Each pair of numbers indicates a pair of rows/columns involved in a Givens rotation.

LDGCOL Input parameter.

LDGCOL is INTEGER

The leading dimension of GIVCOL, must be at least N.

GIVNUM Input parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (LDGNUM, 2). Each number indicates the C or S value used in the corresponding Givens rotation.

LDGNUM Input parameter.

LDGNUM is INTEGER

The leading dimension of arrays DIFR, POLES and GIVNUM, must be at least K.

POLES Input parameter.

POLES is REAL

POLES is an array, dimension (LDGNUM, 2). On entry, POLES(1:K, 1) contains the new singular values obtained from solving the secular equation, and POLES(1:K, 2) is an array containing the poles in the secular equation.

DIFL Input parameter.

DIFL is REAL

DIFL is an array, dimension (K).. On entry, DIFL(I) is the distance between I-th updated (undeflated) singular value and the I-th (undeflated) old singular value.

DIFR Input parameter.

DIFR is REAL

DIFR is an array, dimension (LDGNUM, 2).. On entry, DIFR(I, 1) contains the distances between I-th updated (undeflated) singular value and the I+1-th (undeflated) old singular value. And DIFR(I, 2) is the normalizing factor for the I-th right singular vector.

Z Input parameter.

Z is REAL

Z is an array, dimension (K). Contain the components of the deflation-adjusted updating row vector.

K Input parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. 1 <= K <=N.

C Input parameter.

C is REAL

C contains garbage if SQRE =0 and the C-value of a Givens rotation related to the right null space if SQRE = 1.

S Input parameter.

S is REAL

S contains garbage if SQRE =0 and the S-value of a Givens rotation related to the right null space if SQRE = 1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (K) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *clals0*, *dlals0* and *zlals0*.

4.17.478 slalsa

slalsa is an itermediate step in solving the least squares problem by computing the SVD of the coefficient matrix in compact form (The singular vectors are computed as products of simple orthorgonal matrices.).

If ICOMPQ = 0, slalsa applies the inverse of the left singular vector matrix of an upper bidiagonal matrix to the right hand side; and if ICOMPQ = 1, slalsa applies the right singular vector matrix to the right hand side. The singular vector matrices were generated in compact form by slalsa.

Syntax

Fortran specification:

```
use armpl_library

subroutine slalsa(ICOMPQ, SMLSIZ, N, NRHS, B, LDB, BX, LDBX, U, LDU, VT, K,
                  DIFL, DIFR, Z, POLES, GIVPTR, GIVCOL, LDGCOL, PERM, GIVNUM,
                  C, S, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slalsa_(const armpl_int_t *icompq, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *nrhs, float *b,
             const armpl_int_t *ldb, float *bx, const armpl_int_t *ldbx,
             const float *u, const armpl_int_t *ldu, const float *vt,
             const armpl_int_t *k, const float *difl, const float *difr,
             const float *z, const float *poles, const armpl_int_t *givptr,
             const armpl_int_t *givcol, const armpl_int_t *ldgcol,
             const armpl_int_t *perm, const float *givnum, const float *c,
             const float *s, float *work, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether the left or the right singular vector matrix is involved. = 0: Left singular vector matrix = 1: Right singular vector matrix

SMLSIZ Input parameter.

SMLSIZ is INTEGER

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

N is INTEGER

The row and column dimensions of the upper bidiagonal matrix.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B and BX. NRHS must be at least 1.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem in rows 1 through M. On output, B contains the solution X in rows 1 through N.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B in the calling subprogram. LDB must be at least max(1,MAX(M, N)).

BX Output parameter.

BX is REAL

BX is an array, dimension (LDBX, NRHS). On exit, the result of applying the left or right singular vector matrix to B.

LDBX Input parameter.

LDBX is INTEGER

The leading dimension of BX.

U Input parameter.

U is REAL

U is an array, dimension (LDU, SMLSIZ).. On entry, U contains the left singular vector matrices of all subproblems at the bottom level.

LDU Input parameter.

LDU is INTEGER, LDU = > N.

The leading dimension of arrays U, VT, DIFL, DIFR, POLES, GIVNUM, and Z.

VT Input parameter.

VT is REAL

VT is an array, dimension (LDU, SMLSIZ+1).. On entry, VT^T contains the right singular vector matrices of all subproblems at the bottom level.

K Input parameter.

K is INTEGER array, dimension (N).

DIFL Input parameter.

DIFL is REAL

DIFL is an array, dimension (LDU, NLVL).. where NLVL = INT(log_2 (N/(SMLSIZ+1))) + 1.

DIFR Input parameter.

DIFR is REAL

DIFR is an array, dimension (LDU, 2 * NLVL).. On entry, DIFL(*, I) and DIFR(*, 2 * I -1) record distances between singular values on the I-th level and singular values on the (I -1)-th level, and DIFR(*, 2 * I) record the normalizing factors of the right singular vectors matrices of subproblems on I-th level.

Z Input parameter.

Z is REAL

Z is an array, dimension (LDU, NLVL).. On entry, Z(1, I) contains the components of the deflation- adjusted updating row vector for subproblems on the I-th level.

POLES Input parameter.

POLES is REAL

POLES is an array, dimension (LDU, 2 * NLVL).. On entry, POLES(*, 2 * I -1: 2 * I) contains the new and old singular values involved in the secular equations on the I-th level.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N).

On entry, GIVPTR(I) records the number of Givens rotations performed on the I-th problem on the computation tree.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2 * NLVL).

On entry, for each I, GIVCOL(*, 2 * I - 1: 2 * I) records the locations of Givens rotations performed on the I-th level on the computation tree.

LDGCOL Input parameter.

LDGCOL is INTEGER, LDGCOL = > N.

The leading dimension of arrays GIVCOL and PERM.

PERM Input parameter.

PERM is INTEGER array, dimension (LDGCOL, NLVL).

On entry, PERM(*, I) records permutations done on the I-th level of the computation tree.

GIVNUM Input parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (LDU, 2 * NLVL).. On entry, GIVNUM(*, 2 *I -1 : 2 * I) records the C- and S- values of Givens rotations performed on the I-th level on the computation tree.

C Input parameter.

C is REAL

C is an array, dimension (N).. On entry, if the I-th subproblem is not square, C(I) contains the C-value of a Givens rotation related to the right null space of the I-th subproblem.

S Input parameter.

S is REAL

S is an array, dimension (N).. On entry, if the I-th subproblem is not square, S(I) contains the S-value of a Givens rotation related to the right null space of the I-th subproblem.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (3*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

4.17.479 slalsd

slalsd uses the singular value decomposition of A to solve the least squares problem of finding X to minimize the Euclidean norm of each column of A*X-B, where A is N-by-N upper bidiagonal, and X and B are N-by-NRHS. The solution X overwrites B.

The singular values of A smaller than RCOND times the largest singular value are treated as zero in solving the least squares problem; in this case a minimum norm solution is returned. The actual singular values are returned in D in ascending order.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine slalsd(UPLO, SMLSIZ, N, NRHS, D, E, B, LDB, RCOND, RANK, WORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slalsd_(const char *uplo, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *nrhs, float *d,
             float *e, float *b, const armpl_int_t *ldb, const float *rcond,
             armpl_int_t *rank, float *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': D and E define an upper bidiagonal matrix. = 'L': D and E define a lower bidiagonal matrix.

SMLSIZ Input parameter.

SMLSIZ is INTEGER

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

N is INTEGER

The dimension of the bidiagonal matrix. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B. NRHS must be at least 1.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry D contains the main diagonal of the bidiagonal matrix. On exit, if INFO = 0, D contains its singular values.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). Contains the super-diagonal entries of the bidiagonal matrix. On exit, E has been destroyed.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem. On output, B contains the solution X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B in the calling subprogram. LDB must be at least max(1, N).

RCOND Input parameter.

RCOND is REAL

The singular values of A less than or equal to RCOND times the largest singular value are treated as zero in solving the least squares problem. If RCOND is negative, machine precision is used instead. For example, if diag(S)*X=B were the least squares problem, where diag(S) is a diagonal matrix of singular values, the

solution would be X(i) = B(i) / S(i) if S(i) is greater than RCOND*max(S), and X(i) = 0 if S(i) is less than or equal to RCOND*max(S).

RANK Output parameter.

RANK is INTEGER

The number of singular values of A greater than RCOND times the largest singular value.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension at least. (9* N + 2*N* SMLSIZ + 8*N*NLVL + N* NRHS + (SMLSIZ+1)**2), where NLVL = max(0, INT(log_2 (N/(SMLSIZ+1))) + 1).

IWORK Output parameter.

IWORK is INTEGER array, dimension at least

(3*N*NLVL + 11*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute a singular value while working on the submatrix lying in rows and columns INFO/(N+1) through MOD(INFO,N+1).

4.17.480 slamrg

slamrg will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

Syntax

Fortran specification:

```
use armpl_library

subroutine slamrg(N1, N2, A, STRD1, STRD2, INDEX)
```

C specification:

```
#include "armpl.h"

void slamrg_(const armpl_int_t *n1, const armpl_int_t *n2, const float *a,
             const armpl_int_t *strd1, const armpl_int_t *strd2,
             armpl_int_t *index);
```

Parameters

N1 Input parameter.

N1 is INTEGER

N2 Input parameter.

N2 is INTEGER

These arguments contain the respective lengths of the two sorted lists to be merged.

A Input parameter.

A is REAL

A is an array, dimension (N1+N2). The first N1 elements of A contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final N2 elements.

STRD1 Input parameter.

STRD1 is INTEGER

STRD2 Input parameter.

STRD2 is INTEGER

These are the strides to be taken through the array A. Allowable strides are 1 and -1. They indicate whether a subset of A is sorted in ascending (STRDx = 1) or descending (STRDx = -1) order.

INDEX Output parameter.

INDEX is INTEGER array, dimension (N1+N2)

On exit this array will contain a permutation such that if B(I) = A(INDEX(I)) for I=1,N1+N2, then B will be sorted in ascending order.

Related Information

For this routine in other precisions, please see *dlamrg*.

4.17.481 slamswlq

SLAMSWLQ overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by short wide LQ factorization (SLASWLQ)

Syntax

Fortran specification:

```
use armpl_library

subroutine slamswlq(SIDE, TRANS, M, N, K, MB, NB, A, LDA, T, LDT, C, LDC,
                    WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slamswlq_(const char *side, const char *trans, const armpl_int_t *m,
               const armpl_int_t *n, const armpl_int_t *k,
               const armpl_int_t *mb, const armpl_int_t *nb, float *a,
               const armpl_int_t *lda, const float *t, const armpl_int_t *ldt,
               float *c, const armpl_int_t *ldc, float *work,
               const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0;

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. M >= MB >= 1

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. NB > M.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. MB > M.

A Input parameter.

A is REAL

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the blocked elementary reflector H(i), for i = 1,2,. . . ,k, as returned by SLASWLQ in the first k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is REAL

T is an array, dimension. (M * Number of blocks(CEIL(N-K/NB-K)), The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) REAL

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, NB) * MB; if SIDE = 'R', LWORK >= max(1, M) * MB. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clamswlq*, *dlamswlq* and *zlamswlq*.

4.17.482 slamtsqr

SLAMTSQR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by tall skinny QR factorization (DLATSQR)

Syntax

Fortran specification:

```
use armpl_library

subroutine slamtsqr(SIDE, TRANS, M, N, K, MB, NB, A, LDA, T, LDT, C, LDC,
                    WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slamtsqr_(const char *side, const char *trans, const armpl_int_t *m,
               const armpl_int_t *n, const armpl_int_t *k,
               const armpl_int_t *mb, const armpl_int_t *nb, float *a,
               const armpl_int_t *lda, const float *t, const armpl_int_t *ldt,
               float *c, const armpl_int_t *ldc, float *work,
               const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0;

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. MB > N. (must be the same as DLATSQR)

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. N >= NB >= 1.

A Input parameter.

A is REAL

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the blockedelementary reflector H(i), for i = 1,2,...,k, as returned by DLATSQR in the first k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is REAL

T is an array, dimension. (N * Number of blocks(CEIL(M-K/MB-K)), The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) REAL

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If SIDE = 'L', LWORK >= max(1, N)*NB; if SIDE = 'R', LWORK >= max(1, MB)*NB. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clamtsqr*, *dlamtsqr* and *zlamtsqr*.

4.17.483 slaneg

slaneg computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal T - sigma I = L D L^T. This implementation works directly on the factors without forming the tridiagonal matrix T. The Sturm count is also the number of eigenvalues of T less than sigma.

This routine is called from SLARRB.

The current routine does not use the PIVMIN parameter but rather requires IEEE-754 propagation of Infinities and NaNs. This routine also has no input range restrictions but does require default exception handling such that x/0 produces Inf when x is non-zero, and Inf/Inf produces NaN. For more information, see:

```
Marques, Riedy, and Voemel, "Benefits of IEEE-754 Features in
Modern Symmetric Tridiagonal Eigensolvers," SIAM Journal on
Scientific Computing, v28, n5, 2006.  DOI 10.1137/050641624
(Tech report version in LAWN 172 with the same title.)
```

Syntax

Fortran specification:

```
use armpl_library

integer function slaneg(N, D, LLD, SIGMA, PIVMIN, R)
```

C specification:

```
#include "armpl.h"

armpl_int_t slaneg_(const armpl_int_t *n, const float *d, const float *lld,
                    const float *sigma, const float *pivmin,
                    const armpl_int_t *r);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix.

D Input parameter.

D is REAL

D is an array, dimension (N). The N diagonal elements of the diagonal matrix D.

LLD Input parameter.

LLD is REAL

LLD is an array, dimension (N-1). The (N-1) elements L(i)*L(i)*D(i).

SIGMA Input parameter.

SIGMA is REAL

Shift amount in T - sigma I = L D L^T.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot in the Sturm sequence. May be used when zero pivots are encountered on non-IEEE-754 architectures.

R Input parameter.

R is INTEGER

The twist index for the twisted factorization that is used for the negcount.

Related Information

For this routine in other precisions, please see *dlaneg*.

4.17.484 slangb

slangb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n band matrix A, with kl sub-diagonals and ku super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

real function slangb(NORM, N, KL, KU, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

float slangb_(const char *norm, const armpl_int_t *n, const armpl_int_t *kl,
              const armpl_int_t *ku, const float *ab, const armpl_int_t *ldab,
              float *work, ... );
```

Returns

SLANGB = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in SLANGB as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, SLANGB is set to zero.

KL Input parameter.

KL is INTEGER

The number of sub-diagonals of the matrix A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of super-diagonals of the matrix A. KU >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clangb*, *dlangb* and *zlangb*.

4.17.485 slange

`slange` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function slange(NORM, M, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

float slange_(const char *norm, const armpl_int_t *m, const armpl_int_t *n,
              const float *a, const armpl_int_t *lda, float *work, ... );
```

Returns

SLANGE = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in SLANGE as described above.

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0. When `M` = 0, SLANGE is set to zero.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0. When `N` = 0, SLANGE is set to zero.

A Input parameter.

`A` is `REAL`

`A` is an array, dimension (`LDA`, `N`). The m by n matrix `A`.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(`M`,1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clange*, *dlange* and *zlange*. It also exists with a native C interface as *LAPACKE_slange*.

4.17.486 slangt

slangt returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function slangt(NORM, N, DL, D, DU)
```

C specification:

```
#include "armpl.h"

float slangt_(const char *norm, const armpl_int_t *n, const float *dl,
              const float *d, const float *du, ... );
```

Returns

SLANGT = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in SLANGT as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, SLANGT is set to zero.

DL Input parameter.

DL is REAL

DL is an array, dimension (N-1). The (n-1) sub-diagonal elements of A.

D Input parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of A.

DU Input parameter.

DU is REAL

DU is an array, dimension (N-1). The (n-1) super-diagonal elements of A.

Related Information

For this routine in other precisions, please see *clangt*, *dlangt* and *zlangt*.

4.17.487 slanhs

slanhs returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hessenberg matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function slanhs(NORM, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

float slanhs_(const char *norm, const armpl_int_t *n, const float *a,
              const armpl_int_t *lda, float *work, ... );
```

Returns

SLANHS = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in SLANHS as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, SLANHS is set to zero.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The n by n upper Hessenberg matrix A; the part of A below the first sub-diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clanhs*, *dlanhs* and *zlanhs*.

4.17.488 slansb

slansb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n symmetric band matrix A, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

real function slansb(NORM, UPLO, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

float slansb_(const char *norm, const char *uplo, const armpl_int_t *n,
              const armpl_int_t *k, const float *ab, const armpl_int_t *ldab,
              float *work, ... );
```

Returns

SLANSB = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in SLANSB as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the band matrix A is supplied. = 'U': Upper triangular part is supplied = 'L': Lower triangular part is supplied

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, SLANSB is set to zero.

K Input parameter.

K is INTEGER

The number of super-diagonals or sub-diagonals of the band matrix A. K >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The upper or lower triangle of the symmetric band matrix A, stored in the first K+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clansb*, *dlansb* and *zlansb*.

4.17.489 slansf

slansf returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric matrix A in RFP format.

Syntax

Fortran specification:

```
use armpl_library

real function slansf(NORM, TRANSR, UPLO, N, A, WORK)
```

C specification:

```
#include "armpl.h"

float slansf_(const char *norm, const char *transr, const char *uplo,
              const armpl_int_t *n, const float *a, float *work, ... );
```

Returns

SLANSF = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in SLANSF as described above.

TRANSR Input parameter.

TRANSR is CHARACTER*1

Specifies whether the RFP format of A is normal or transposed format. = ‘N’: RFP format is Normal; = ‘T’: RFP format is Transpose.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the RFP matrix A came from an upper or lower triangular matrix as follows: = ‘U’: RFP A came from an upper triangular matrix; = ‘L’: RFP A came from a lower triangular matrix.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, SLANSF is set to zero.

A Input parameter.

A is REAL

A is an array, dimension (N*(N+1)/2);. On entry, the upper (if UPLO = ‘U’) or lower (if UPLO = ‘L’) part of the symmetric matrix A stored in RFP format. See the “Notes” below for more details. Unchanged on exit.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = ‘I’ or ‘1’ or ‘O’; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlansf*.

4.17.490 slansp

`slansp` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

real function slansp(NORM, UPLO, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

float slansp_(const char *norm, const char *uplo, const armpl_int_t *n,
              const float *ap, float *work, ... );
```

Returns

SLANSP = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in SLANSP as described above.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the upper or lower triangular part of the symmetric matrix A is supplied. = ‘`U`’: Upper triangular part of A is supplied = ‘`L`’: Lower triangular part of A is supplied

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0. When `N` = 0, SLANSP is set to zero.

AP Input parameter.

`AP` is `REAL`

`AP` is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array `AP` as follows: if `UPLO` = ‘`U`’, AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if `UPLO` = ‘`L`’, AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

WORK Output parameter.

`WORK` is `REAL`

`WORK` is an array, dimension (MAX(1,LWORK)),. where LWORK >= `N` when `NORM` = ‘I’ or ‘1’ or ‘O’; otherwise, `WORK` is not referenced.

Related Information

For this routine in other precisions, please see *clansp*, *dlansp* and *zlansp*.

4.17.491 slanst

`slanst` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function slanst(NORM, N, D, E)
```

C specification:

```
#include "armpl.h"

float slanst_(const char *norm, const armpl_int_t *n, const float *d,
              const float *e, ... );
```

Returns

SLANST = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in SLANST as described above.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0. When `N` = 0, SLANST is set to zero.

D Input parameter.

`D` is `REAL`

`D` is an array, dimension (`N`). The diagonal elements of A.

E Input parameter.

`E` is `REAL`

`E` is an array, dimension (N-1). The (n-1) sub-diagonal or super-diagonal elements of A.

Related Information

For this routine in other precisions, please see *dlanst*.

4.17.492 slansy

`slansy` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function slansy(NORM, UPLO, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

float slansy_(const char *norm, const char *uplo, const armpl_int_t *n,
              const float *a, const armpl_int_t *lda, float *work, ... );
```

Returns

SLANSY = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in SLANSY as described above.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the upper or lower triangular part of the symmetric matrix `A` is to be referenced. = ‘`U`’: Upper triangular part of `A` is referenced = ‘`L`’: Lower triangular part of `A` is referenced

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0. When `N` = 0, SLANSY is set to zero.

A Input parameter.

`A` is `REAL`

`A` is an array, dimension (`LDA`, `N`). The symmetric matrix `A`. If `UPLO` = ‘`U`’, the leading n by n upper triangular part of `A` contains the upper triangular part of the matrix `A`, and the strictly lower triangular part of A is not

referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clansy*, *dlansy* and *zlansy*. It also exists with a native C interface as *LAPACKE_slansy*.

4.17.493 slantb

slantb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n triangular band matrix A, with (k + 1) diagonals.

Syntax

Fortran specification:

```
use armpl_library

real function slantb(NORM, UPLO, DIAG, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

float slantb_(const char *norm, const char *uplo, const char *diag,
              const armpl_int_t *n, const armpl_int_t *k, const float *ab,
              const armpl_int_t *ldab, float *work, ... );
```

Returns

SLANTB = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in SLANTB as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, SLANTB is set to zero.

K Input parameter.

K is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals of the matrix A if UPLO = 'L'. K >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first k+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k). Note that when DIAG = 'U', the elements of the array AB corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clantb*, *dlantb* and *zlantb*.

4.17.494 slantp

slantp returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

real function slantp(NORM, UPLO, DIAG, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

float slantp_(const char *norm, const char *uplo, const char *diag,
              const armpl_int_t *n, const float *ap, float *work, ... );
```

Returns

SLANTP = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in SLANTP as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = ‘U’: Upper triangular = ‘L’: Lower triangular

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = ‘N’: Non-unit triangular = ‘U’: Unit triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, SLANTP is set to zero.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = ‘U’, AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = ‘L’, AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. Note that when DIAG = ‘U’, the elements of the array AP corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = ‘I’; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clantp*, *dlantp* and *zlantp*.

4.17.495 slantr

`slantr` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function slantr(NORM, UPLO, DIAG, M, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

float slantr_(const char *norm, const char *uplo, const char *diag,
              const armpl_int_t *m, const armpl_int_t *n, const float *a,
              const armpl_int_t *lda, float *work, ... );
```

Returns

SLANTR = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in SLANTR as described above.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the matrix `A` is upper or lower trapezoidal. = ‘`U`’: Upper trapezoidal = ‘`L`’: Lower trapezoidal Note that `A` is triangular instead of trapezoidal if `M` = `N`.

DIAG Input parameter.

`DIAG` is `CHARACTER*1`

Specifies whether or not the matrix `A` has unit diagonal. = ‘`N`’: Non-unit diagonal = ‘`U`’: Unit diagonal

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0, and if `UPLO` = ‘`U`’, `M` <= `N`. When `M` = 0, SLANTR is set to zero.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0, and if `UPLO` = ‘`L`’, `N` <= `M`. When `N` = 0, SLANTR is set to zero.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The trapezoidal matrix A (A is triangular if M = N). If UPLO = 'U', the leading m by n upper trapezoidal part of the array A contains the upper trapezoidal matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading m by n lower trapezoidal part of the array A contains the lower trapezoidal matrix, and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be one.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clantr*, *dlantr* and *zlantr*. It also exists with a native C interface as *LAPACKE_slantr*.

4.17.496 slanv2

slanv2 computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form:

```
[ A   B ] = [ CS -SN ] [ AA  BB ] [ CS  SN ]
[ C   D ]   [ SN  CS ] [ CC  DD ] [-SN  CS ]
```

where either 1) CC = 0 so that AA and DD are real eigenvalues of the matrix, or 2) AA = DD and BB*CC < 0, so that AA + or - sqrt(BB*CC) are complex conjugate eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine slanv2(A, B, C, D, RT1R, RT1I, RT2R, RT2I, CS, SN)
```

C specification:

```
#include "armpl.h"

void slanv2_(float *a, float *b, float *c, float *d, float *rt1r, float *rt1i,
             float *rt2r, float *rt2i, float *cs, float *sn);
```

Parameters

A Input and output parameter.

A is REAL

B Input and output parameter.

B is REAL

C Input and output parameter.

C is REAL

D Input and output parameter.

D is REAL

On entry, the elements of the input matrix. On exit, they are overwritten by the elements of the standardised Schur form.

RT1R Output parameter.

RT1R is REAL

RT1I Output parameter.

RT1I is REAL

RT2R Output parameter.

RT2R is REAL

RT2I Output parameter.

RT2I is REAL

The real and imaginary parts of the eigenvalues. If the eigenvalues are a complex conjugate pair, RT1I > 0.

CS Output parameter.

CS is REAL

SN Output parameter.

SN is REAL

Parameters of the rotation matrix.

Related Information

For this routine in other precisions, please see *dlanv2*.

4.17.497 slapll

Given two column vectors X and Y, let

```
A = ( X Y ).
```

The subroutine first computes the QR factorization of A = Q*R, and then computes the SVD of the 2-by-2 upper triangular matrix R. The smaller singular value of R is returned in SSMIN, which is used as the measurement of the linear dependency of the vectors X and Y.

Syntax

Fortran specification:

```
use armpl_library

subroutine slapll(N, X, INCX, Y, INCY, SSMIN)
```

C specification:

```
#include "armpl.h"

void slapll_(const armpl_int_t *n, float *x, const armpl_int_t *incx,
             float *y, const armpl_int_t *incy, float *ssmin);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors X and Y.

X Input and output parameter.

X is REAL

X is an array,. dimension (1+(N-1)*INCX) On entry, X contains the N-vector X. On exit, X is overwritten.

INCX Input parameter.

INCX is INTEGER

The increment between successive elements of X. INCX > 0.

Y Input and output parameter.

Y is REAL

Y is an array,. dimension (1+(N-1)*INCY) On entry, Y contains the N-vector Y. On exit, Y is overwritten.

INCY Input parameter.

INCY is INTEGER

The increment between successive elements of Y. INCY > 0.

SSMIN Output parameter.

SSMIN is REAL

The smallest singular value of the N-by-2 matrix A = (X Y).

Related Information

For this routine in other precisions, please see *clapll*, *dlapll* and *zlapll*.

4.17.498 slapmr

slapmr rearranges the rows of the M by N matrix X as specified by the permutation K(1),K(2),...,K(M) of the integers 1,...,M. If FORWRD = .TRUE., forward permutation:

```
X(K(I),*) is moved X(I,*) for I = 1,2,...,M.
```

If FORWRD = .FALSE., backward permutation:

```
X(I,*) is moved to X(K(I),*) for I = 1,2,...,M.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slapmr(FORWRD, M, N, X, LDX, K)
```

C specification:

```
#include "armpl.h"

void slapmr_(const armpl_int_t *forwrd, const armpl_int_t *m,
             const armpl_int_t *n, float *x, const armpl_int_t *ldx,
             armpl_int_t *k);
```

Parameters

FORWRD Input parameter.

FORWRD is LOGICAL

= .TRUE., forward permutation = .FALSE., backward permutation

M Input parameter.

M is INTEGER

The number of rows of the matrix X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix X. N >= 0.

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, N). On entry, the M by N matrix X. On exit, X contains the permuted matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X, LDX >= MAX(1, M).

K Input and output parameter.

K is INTEGER array, dimension (M)

On entry, K contains the permutation vector. K is used as internal workspace, but reset to its original value on output.

Related Information

For this routine in other precisions, please see *clapmr*, *dlapmr* and *zlapmr*. It also exists with a native C interface as *LAPACKE_slapmr*.

4.17.499 slapmt

slapmt rearranges the columns of the M by N matrix X as specified by the permutation K(1),K(2),...,K(N) of the integers 1,...,N. If FORWRD = .TRUE., forward permutation:

```
X(*,K(J)) is moved X(*,J) for J = 1,2,...,N.
```

If FORWRD = .FALSE., backward permutation:

```
X(*,J) is moved to X(*,K(J)) for J = 1,2,...,N.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slapmt(FORWRD, M, N, X, LDX, K)
```

C specification:

```
#include "armpl.h"

void slapmt_(const armpl_int_t *forwrd, const armpl_int_t *m,
             const armpl_int_t *n, float *x, const armpl_int_t *ldx,
             armpl_int_t *k);
```

Parameters

FORWRD Input parameter.

FORWRD is LOGICAL

= .TRUE., forward permutation = .FALSE., backward permutation

M Input parameter.

M is INTEGER

The number of rows of the matrix X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix X. N >= 0.

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, N). On entry, the M by N matrix X. On exit, X contains the permuted matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X, LDX >= MAX(1, M).

K Input and output parameter.

K is INTEGER array, dimension (N)

On entry, K contains the permutation vector. K is used as internal workspace, but reset to its original value on output.

Related Information

For this routine in other precisions, please see *clapmt*, *dlapmt* and *zlapmt*. It also exists with a native C interface as *LAPACKE_slapmt*.

4.17.500 slapy2

`slapy2` returns sqrt(x**2+y**2), taking care not to cause unnecessary overflow.

Syntax

Fortran specification:

```
use armpl_library

real function slapy2(X, Y)
```

C specification:

```
#include "armpl.h"

float slapy2_(const float *x, const float *y);
```

Parameters

X Input parameter.

X is REAL

Y Input parameter.

Y is REAL

X and Y specify the values x and y.

Related Information

For this routine in other precisions, please see *dlapy2*. It also exists with a native C interface as *LAPACKE_slapy2*.

4.17.501 slapy3

`slapy3` returns sqrt(x**2+y**2+z**2), taking care not to cause unnecessary overflow.

Syntax

Fortran specification:

```
use armpl_library

real function slapy3(X, Y, Z)
```

C specification:

```
#include "armpl.h"

float slapy3_(const float *x, const float *y, const float *z);
```

Parameters

X Input parameter.

X is REAL

Y Input parameter.

Y is REAL

Z Input parameter.

Z is REAL

X, Y and Z specify the values x, y and z.

Related Information

For this routine in other precisions, please see *dlapy3*. It also exists with a native C interface as *LAPACKE_slapy3*.

4.17.502 slaqgb

slaqgb equilibrates a general M by N band matrix A with KL subdiagonals and KU superdiagonals using the row and scaling factors in the vectors R and C.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqgb(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void slaqgb_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku, float *ab,
             const armpl_int_t *ldab, const float *r, const float *c,
             const float *rowcnd, const float *colcnd, const float *amax,
             char *equed, ... );
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, the equilibrated matrix, in the same storage format as A. See EQUED for the form of the equilibrated matrix.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDA >= KL+KU+1.

R Input parameter.

R is REAL

R is an array, dimension (M). The row scale factors for A.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A.

ROWCND Input parameter.

ROWCND is REAL

Ratio of the smallest R(i) to the largest R(i).

COLCND Input parameter.

COLCND is REAL

Ratio of the smallest C(i) to the largest C(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C).

Related Information

4.17.503 slaqge

slaqge equilibrates a general M by N matrix A using the row and column scaling factors in the vectors R and C.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqge(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void slaqge_(const armpl_int_t *m, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, const float *r, const float *c,
             const float *rowcnd, const float *colcnd, const float *amax,
             char *equed, ... );
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M by N matrix A. On exit, the equilibrated matrix. See EQUED for the form of the equilibrated matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

R Input parameter.

R is REAL

R is an array, dimension (M). The row scale factors for A.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A.

ROWCND Input parameter.

ROWCND is REAL

Ratio of the smallest R(i) to the largest R(i).

COLCND Input parameter.

COLCND is REAL

Ratio of the smallest C(i) to the largest C(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C).

4.17.504 slaqp2

slaqp2 computes a QR factorization with column pivoting of the block A(OFFSET+1:M,1:N). The block A(1:OFFSET,1:N) is accordingly pivoted, but not factorized.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqp2(M, N, OFFSET, A, LDA, JPVT, TAU, VN1, VN2, WORK)
```

C specification:

```
#include "armpl.h"

void slaqp2_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *offset, float *a, const armpl_int_t *lda,
             armpl_int_t *jpvt, float *tau, float *vn1, float *vn2,
             float *work);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

OFFSET Input parameter.

OFFSET is INTEGER

The number of rows of the matrix A that must be pivoted but no factorized. OFFSET >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the upper triangle of block A(OFFSET+1:M,1:N) is the triangular factor obtained; the elements in block A(OFFSET+1:M,1:N) below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. Block A(1:OFFSET,1:N) has been accordingly pivoted, but no factorized.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of A*P (a leading column); if JPVT(i) = 0, the i-th column of A is a free column. On exit, if JPVT(i) = k, then the i-th column of A*P was the k-th column of A.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors.

VN1 Input and output parameter.

VN1 is REAL

VN1 is an array, dimension (N). The vector with the partial column norms.

VN2 Input and output parameter.

VN2 is REAL

VN2 is an array, dimension (N). The vector with the exact column norms.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

Related Information

For this routine in other precisions, please see *claqp2*, *dlaqp2* and *zlaqp2*.

4.17.505 slaqps

slaqps computes a step of QR factorization with column pivoting of a real M-by-N matrix A by using Blas-3. It tries to factorize NB columns from A starting from the row OFFSET+1, and updates all of the matrix with Blas-3 xGEMM.

In some cases, due to catastrophic cancellations, it cannot factorize NB columns. Hence, the actual number of factorized columns is returned in KB.

Block A(1:OFFSET,1:N) is accordingly pivoted, but not factorized.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqps(M, N, OFFSET, NB, KB, A, LDA, JPVT, TAU, VN1, VN2, AUXV, F,
                  LDF)
```

C specification:

```
#include "armpl.h"

void slaqps_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *offset, const armpl_int_t *nb,
             armpl_int_t *kb, float *a, const armpl_int_t *lda,
             armpl_int_t *jpvt, float *tau, float *vn1, float *vn2,
             float *auxv, float *f, const armpl_int_t *ldf);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0

OFFSET Input parameter.

OFFSET is INTEGER

The number of rows of A that have been factorized in previous steps.

NB Input parameter.

NB is INTEGER

The number of columns to factorize.

KB Output parameter.

KB is INTEGER

The number of columns actually factorized.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, block A(OFFSET+1:M,1:KB) is the triangular factor obtained and block A(1:OFFSET,1:N) has been accordingly pivoted, but no factorized. The rest of the matrix, block A(OFFSET+1:M,KB+1:N) has been updated.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

JPVT(I) = K <==> Column K of the full matrix A has been permuted into position I in AP.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (KB). The scalar factors of the elementary reflectors.

VN1 Input and output parameter.

VN1 is REAL

VN1 is an array, dimension (N). The vector with the partial column norms.

VN2 Input and output parameter.

VN2 is REAL

VN2 is an array, dimension (N). The vector with the exact column norms.

AUXV Input and output parameter.

AUXV is REAL

AUXV is an array, dimension (NB). Auxiliar vector.

F Input and output parameter.

F is REAL

F is an array, dimension (LDF, NB). Matrix $F^T = L*Y^T *A$.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the array F. LDF >= max(1, N).

Related Information

For this routine in other precisions, please see *claqps*, *dlaqps* and *zlaqps*.

4.17.506 slaqr0

```
SLAQR0 computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**T, where T is an upper quasi-triangular matrix (the
   Schur form), and Z is the orthogonal matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input orthogonal
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the orthogonal matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqr0(WANTT, WANTZ, N, ILO, IHI, H, LDH, WR, WI, ILOZ, IHIZ, Z,
                  LDZ, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slaqr0_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, float *h, const armpl_int_t *ldh,
             float *wr, float *wi, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, float *z, const armpl_int_t *ldz,
             float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1, H(ILO,ILO-1) is zero. ILO and IHI are normally set by a previous call to SGEBAL, and then passed to SGEHRD when the matrix output by SGEBAL is reduced to Hessenberg form. Otherwise, ILO and IHI should be set to 1 and N, respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is REAL

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and WANTT is .TRUE., then H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1).LT.0. If INFO = 0 and WANTT is .FALSE., then the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

This subroutine may explicitly set H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

WR Output parameter.

WR is REAL

WR is an array, dimension (IHI) .

WI Output parameter.

WI is REAL

WI is an array, dimension (IHI). The real and imaginary parts, respectively, of the computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored in WR(ILO:IHI) and WI(ILO:IHI). If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with WI(i) .GT. 0 and WI(i+1) .LT. 0. If WANTT is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with WR(i) = H(i,i) and, if H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) = sqrt(-H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, IHI). If WANTZ is .FALSE., then Z is not referenced. If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the orthogonal Schur factor of H(ILO:IHI,ILO:IHI). (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if WANTZ is .TRUE. then LDZ.GE.MAX(1, IHIZ). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension LWORK. On exit, if LWORK = -1, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient, but LWORK typically as large as 6* N may be required for optimal performance. A workspace query to determine the optimal workspace size is recommended.

If LWORK = -1, then SLAQR0 does a workspace query. In this case, SLAQR0 checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: if INFO = i, SLAQR0 failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and WANT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is an orthogonal matrix. The final value of H is upper Hessenberg and quasi-triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit

(final value of Z(ILO:IHI,ILOZ:IHIZ) = (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

where U is the orthogonal matrix in (*) (regard- less of the value of WANTT.)

If INFO .GT. 0 and WANTZ is .FALSE., then Z is not accessed.

Related Information

For this routine in other precisions, please see *claqr0*, *dlaqr0* and *zlaqr0*.

4.17.507 slaqr1

```
Given a 2-by-2 or 3-by-3 matrix H, SLAQR1 sets v to a
     scalar multiple of the first column of the product

     (*)  K = (H - (sr1 + i*si1)*I)*(H - (sr2 + i*si2)*I)

     scaling to avoid overflows and most underflows. It
     is assumed that either

               1) sr1 = sr2 and si1 = -si2
          or
               2) si1 = si2 = 0.

     This is useful for starting double implicit shift bulges
     in the QR algorithm.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqr1(N, H, LDH, SR1, SI1, SR2, SI2, V)
```

C specification:

```
#include "armpl.h"

void slaqr1_(const armpl_int_t *n, const float *h, const armpl_int_t *ldh,
             const float *sr1, float *si1, float *sr2, float *si2, float *v);
```

Parameters

N Input parameter.

N is INTEGER

Order of the matrix H. N must be either 2 or 3.

H Input parameter.

H is REAL

H is an array, dimension (LDH, N). The 2-by-2 or 3-by-3 matrix H in (*).

LDH Input parameter.

LDH is INTEGER

The leading dimension of H as declared in the calling procedure. LDH.GE.N

SR1 Input parameter.

SR1 is REAL

SI1 Input parameter.

SI1 is REAL

SR2 Input parameter.

SR2 is REAL

SI2 Input parameter.

SI2 is REAL

The shifts in (*).

V Output parameter.

V is REAL

V is an array, dimension (N). A scalar multiple of the first column of the matrix K in (*).

Related Information

For this routine in other precisions, please see *claqr1*, *dlaqr1* and *zlaqr1*.

4.17.508 slaqr2

```
SLAQR2 is identical to SLAQR3 except that it avoids
   recursion by calling SLAHQR instead of SLAQR4.

   Aggressive early deflation:

   This subroutine accepts as input an upper Hessenberg matrix
   H and performs an orthogonal similarity transformation
   designed to detect and deflate fully converged eigenvalues from
   a trailing principal submatrix.  On output H has been over-
   written by a new Hessenberg matrix that is a perturbation of
   an orthogonal similarity transformation of H.  It is to be
   hoped that the final version of H has many zero subdiagonal
   entries.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqr2(WANTT, WANTZ, N, KTOP, KBOT, NW, H, LDH, ILOZ, IHIZ, Z, LDZ,
                  NS, ND, SR, SI, V, LDV, NH, T, LDT, NV, WV, LDWV, WORK,
                  LWORK)
```

C specification:

```
#include "armpl.h"

void slaqr2_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ktop,
             const armpl_int_t *kbot, const armpl_int_t *nw, float *h,
             const armpl_int_t *ldh, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, float *z, const armpl_int_t *ldz,
             armpl_int_t *ns, armpl_int_t *nd, float *sr, float *si, float *v,
             const armpl_int_t *ldv, const armpl_int_t *nh, float *t,
             const armpl_int_t *ldt, const armpl_int_t *nv, float *wv,
             const armpl_int_t *ldwv, float *work, const armpl_int_t *lwork);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

If .TRUE., then the Hessenberg matrix H is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then only enough of H is updated to preserve the eigenvalues.

WANTZ Input parameter.

WANTZ is LOGICAL

If .TRUE., then the orthogonal matrix Z is updated so so that the orthogonal Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then Z is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix H and (if WANTZ is .TRUE.) the order of the orthogonal matrix Z.

KTOP Input parameter.

KTOP is INTEGER

It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

KBOT Input parameter.

KBOT is INTEGER

It is assumed without a check that either KBOT = N or H(KBOT+1, KBOT)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

NW Input parameter.

NW is INTEGER

Deflation window size. 1 .LE. NW .LE. (KBOT-KTOP+1).

H Input and output parameter.

H is REAL

H is an array, dimension (LDH, N). On input the initial N-by-N section of H stores the Hessenberg matrix undergoing aggressive early deflation. On output H has been transformed by an orthogonal similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

LDH Input parameter.

LDH is INTEGER

Leading dimension of H just as declared in the calling subroutine. N .LE. LDH

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). IF WANTZ is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ is .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of Z just as declared in the calling subroutine. 1 .LE. LDZ.

NS Output parameter.

NS is INTEGER

The number of unconverged (ie approximate) eigenvalues returned in SR and SI that may be used as shifts by the calling subroutine.

ND Output parameter.

ND is INTEGER

The number of converged eigenvalues uncovered by this subroutine.

SR Output parameter.

SR is REAL

SR is an array, dimension (KBOT) .

SI Output parameter.

SI is REAL

SI is an array, dimension (KBOT). On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in SR(KBOT-ND-NS+1) through SR(KBOT-ND) and SI(KBOT-ND-NS+1) through SI(KBOT-ND), respectively. The real and imaginary parts of converged eigenvalues are stored in SR(KBOT-ND+1) through SR(KBOT) and SI(KBOT-ND+1) through SI(KBOT), respectively.

V Output parameter.

V is REAL

V is an array, dimension (LDV, NW). An NW-by-NW work array.

LDV Input parameter.

LDV is INTEGER

The leading dimension of V just as declared in the calling subroutine. NW .LE. LDV

NH Input parameter.

NH is INTEGER

The number of columns of T. NH.GE.NW.

T Output parameter.

T is REAL

T is an array, dimension (LDT, NW) .

LDT Input parameter.

LDT is INTEGER

The leading dimension of T just as declared in the calling subroutine. NW .LE. LDT

NV Input parameter.

NV is INTEGER

The number of rows of work array WV available for workspace. NV.GE.NW.

WV Output parameter.

WV is REAL

WV is an array, dimension (LDWV, NW) .

LDWV Input parameter.

LDWV is INTEGER

The leading dimension of W just as declared in the calling subroutine. NW .LE. LDV

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, WORK(1) is set to an estimate of the optimal value of LWORK for the given values of N, NW, KTOP and KBOT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the work array WORK. LWORK = 2*NW suffices, but greater efficiency may result from larger values of LWORK.

If LWORK = -1, then a workspace query is assumed; SLAQR2 only estimates the optimal workspace size for the given values of N, NW, KTOP and KBOT. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

Related Information

void slaqr3_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ktop,
             const armpl_int_t *kbot, const armpl_int_t *nw, float *h,
             const armpl_int_t *ldh, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, float *z, const armpl_int_t *ldz,
             armpl_int_t *ns, armpl_int_t *nd, float *sr, float *si, float *v,
             const armpl_int_t *ldv, const armpl_int_t *nh, float *t,
             const armpl_int_t *ldt, const armpl_int_t *nv, float *wv,
             const armpl_int_t *ldwv, float *work, const armpl_int_t *lwork);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

If .TRUE., then the Hessenberg matrix H is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then only enough of H is updated to preserve the eigenvalues.

WANTZ Input parameter.

WANTZ is LOGICAL

If .TRUE., then the orthogonal matrix Z is updated so so that the orthogonal Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then Z is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix H and (if WANTZ is .TRUE.) the order of the orthogonal matrix Z.

KTOP Input parameter.

KTOP is INTEGER

It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

KBOT Input parameter.

KBOT is INTEGER

It is assumed without a check that either KBOT = N or H(KBOT+1, KBOT)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

NW Input parameter.

NW is INTEGER

Deflation window size. 1 .LE. NW .LE. (KBOT-KTOP+1).

H Input and output parameter.

H is REAL

H is an array, dimension (LDH, N). On input the initial N-by-N section of H stores the Hessenberg matrix undergoing aggressive early deflation. On output H has been transformed by an orthogonal similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

LDH Input parameter.

LDH is INTEGER

Leading dimension of H just as declared in the calling subroutine. N .LE. LDH

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). IF WANTZ is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ is .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of Z just as declared in the calling subroutine. 1 .LE. LDZ.

NS Output parameter.

NS is INTEGER

The number of unconverged (ie approximate) eigenvalues returned in SR and SI that may be used as shifts by the calling subroutine.

ND Output parameter.

ND is INTEGER

The number of converged eigenvalues uncovered by this subroutine.

SR Output parameter.

SR is REAL

SR is an array, dimension (KBOT) .

SI Output parameter.

SI is REAL

SI is an array, dimension (KBOT). On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in SR(KBOT-ND-NS+1) through SR(KBOT-ND) and SI(KBOT-ND-NS+1) through SI(KBOT-ND), respectively. The real and imaginary parts of converged eigenvalues are stored in SR(KBOT-ND+1) through SR(KBOT) and SI(KBOT-ND+1) through SI(KBOT), respectively.

V Output parameter.

V is REAL

V is an array, dimension (LDV, NW). An NW-by-NW work array.

LDV Input parameter.

LDV is INTEGER

The leading dimension of V just as declared in the calling subroutine. NW .LE. LDV

NH Input parameter.

NH is INTEGER

The number of columns of T. NH.GE.NW.

T Output parameter.

T is REAL

T is an array, dimension (LDT, NW) .

LDT Input parameter.

LDT is INTEGER

The leading dimension of T just as declared in the calling subroutine. NW .LE. LDT

NV Input parameter.

NV is INTEGER

The number of rows of work array WV available for workspace. NV.GE.NW.

WV Output parameter.

WV is REAL

WV is an array, dimension (LDWV, NW) .

LDWV Input parameter.

LDWV is INTEGER

The leading dimension of W just as declared in the calling subroutine. NW .LE. LDV

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, WORK(1) is set to an estimate of the optimal value of LWORK for the given values of N, NW, KTOP and KBOT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the work array WORK. LWORK = 2*NW suffices, but greater efficiency may result from larger values of LWORK.

If LWORK = -1, then a workspace query is assumed; SLAQR3 only estimates the optimal workspace size for the given values of N, NW, KTOP and KBOT. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

Related Information

4.17.510 slaqr4

```
SLAQR4 implements one level of recursion for SLAQR0.
   It is a complete implementation of the small bulge multi-shift
   QR algorithm.  It may be called by SLAQR0 and, for large enough
   deflation window size, it may be called by SLAQR3.  This
   subroutine is identical to SLAQR0 except that it calls SLAQR2
   instead of SLAQR3.
```

(continues on next page)

(continued from previous page)

```
   SLAQR4 computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**T, where T is an upper quasi-triangular matrix (the
   Schur form), and Z is the orthogonal matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input orthogonal
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the orthogonal matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqr4(WANTT, WANTZ, N, ILO, IHI, H, LDH, WR, WI, ILOZ, IHIZ, Z,
                  LDZ, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slaqr4_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, float *h, const armpl_int_t *ldh,
             float *wr, float *wi, const armpl_int_t *iloz,
             const armpl_int_t *ihiz, float *z, const armpl_int_t *ldz,
             float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1, H(ILO,ILO-1) is zero. ILO and IHI are normally set by a previous call to SGEBAL, and then passed to SGEHRD when the matrix output by SGEBAL is reduced to Hessenberg form. Otherwise, ILO and IHI

should be set to 1 and N, respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is REAL

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and WANTT is .TRUE., then H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1).LT.0. If INFO = 0 and WANTT is .FALSE., then the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

This subroutine may explicitly set H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

WR Output parameter.

WR is REAL

WR is an array, dimension (IHI) .

WI Output parameter.

WI is REAL

WI is an array, dimension (IHI). The real and imaginary parts, respectively, of the computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored in WR(ILO:IHI) and WI(ILO:IHI). If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with WI(i) .GT. 0 and WI(i+1) .LT. 0. If WANTT is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with WR(i) = H(i,i) and, if H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) = sqrt(-H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, IHI). If WANTZ is .FALSE., then Z is not referenced. If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the orthogonal Schur factor of H(ILO:IHI,ILO:IHI). (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if WANTZ is .TRUE. then LDZ.GE.MAX(1, IHIZ). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension LWORK. On exit, if LWORK = -1, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient, but LWORK typically as large as 6* N may be required for optimal performance. A workspace query to determine the optimal workspace size is recommended.

If LWORK = -1, then SLAQR4 does a workspace query. In this case, SLAQR4 checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

verbatim INFO is INTEGER = 0: successful exit .GT. 0: if INFO = i, SLAQR4 failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and WANT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is a orthogonal matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit

(final value of Z(ILO:IHI,ILOZ:IHIZ) = (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

where U is the orthogonal matrix in (*) (regard- less of the value of WANTT.)

If INFO .GT. 0 and WANTZ is .FALSE., then Z is not accessed.

                float *v, const armpl_int_t *ldv, float *u,
                const armpl_int_t *ldu, const armpl_int_t *nv, float *wv,
                const armpl_int_t *ldwv, const armpl_int_t *nh, float *wh,
                const armpl_int_t *ldwh);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

WANTT = .true. if the quasi-triangular Schur factor is being computed. WANTT is set to .false. otherwise.

WANTZ Input parameter.

WANTZ is LOGICAL

WANTZ = .true. if the orthogonal Schur factor is being computed. WANTZ is set to .false. otherwise.

KACC22 Input parameter.

KACC22 is INTEGER with value 0, 1, or 2.

Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: SLAQR5 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: SLAQR5 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: SLAQR5 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.

N Input parameter.

N is INTEGER

N is the order of the Hessenberg matrix H upon which this subroutine operates.

KTOP Input parameter.

KTOP is INTEGER

KBOT Input parameter.

KBOT is INTEGER

These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either KTOP = 1 or H(KTOP,KTOP-1) = 0 and either KBOT = N or H(KBOT+1, KBOT) = 0.

NSHFTS Input parameter.

NSHFTS is INTEGER

NSHFTS gives the number of simultaneous shifts. NSHFTS must be positive and even.

SR Input and output parameter.

SR is REAL

SR is an array, dimension (NSHFTS) .

SI Input and output parameter.

SI is REAL

SI is an array, dimension (NSHFTS). SR contains the real parts and SI contains the imaginary parts of the NSHFTS shifts of origin that define the multi-shift QR sweep. On output SR and SI may be reordered.

H Input and output parameter.

H is REAL

H is an array, dimension (LDH, N). On input H contains a Hessenberg matrix. On output a multi-shift QR sweep with shifts SR(J)+i*SI(J) is applied to the isolated diagonal block in rows and columns KTOP through KBOT.

LDH Input parameter.

LDH is INTEGER

LDH is the leading dimension of H just as declared in the calling procedure. LDH.GE.MAX(1, N).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, IHIZ). If WANTZ = .TRUE., then the QR Sweep orthogonal similarity transformation is accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ = .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

LDA is the leading dimension of Z just as declared in the calling procedure. LDZ.GE.N.

V Output parameter.

V is REAL

V is an array, dimension (LDV,NSHFTS/2) .

LDV Input parameter.

LDV is INTEGER

LDV is the leading dimension of V as declared in the calling procedure. LDV.GE.3.

U Output parameter.

U is REAL

U is an array, dimension (LDU,3*NSHFTS-3) .

LDU Input parameter.

LDU is INTEGER

LDU is the leading dimension of U just as declared in the in the calling subroutine. LDU.GE.3*NSHFTS-3.

NH Input parameter.

NH is INTEGER

NH is the number of columns in array WH available for workspace. NH.GE.1.

WH Output parameter.

WH is REAL

WH is an array, dimension (LDWH, NH) .

LDWH Input parameter.

LDWH is INTEGER

Leading dimension of WH just as declared in the calling procedure. LDWH.GE.3*NSHFTS-3.

NV Input parameter.

NV is INTEGER

NV is the number of rows in WV agailable for workspace. NV.GE.1.

WV Output parameter.

WV is REAL

WV is an array, dimension (LDWV,3*NSHFTS-3) .

LDWV Input parameter.

LDWV is INTEGER

LDWV is the leading dimension of WV as declared in the in the calling subroutine. LDWV.GE.NV.

Related Information

For this routine in other precisions, please see *claqr5*, *dlaqr5* and *zlaqr5*.

4.17.512 slaqsb

slaqsb equilibrates a symmetric band matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqsb(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void slaqsb_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             float *ab, const armpl_int_t *ldab, const float *s,
             const float *scond, const float *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

S Input parameter.

S is REAL

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is REAL

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqsb*, *dlaqsb* and *zlaqsb*.

4.17.513 slaqsp

slaqsp equilibrates a symmetric matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqsp(UPLO, N, AP, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void slaqsp_(const char *uplo, const armpl_int_t *n, float *ap,
             const float *s, const float *scond, const float *amax,
             char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the equilibrated matrix: diag(S) * A * diag(S), in the same storage format as A.

S Input parameter.

S is REAL

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is REAL

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqsp*, *dlaqsp* and *zlaqsp*.

4.17.514 slaqsy

slaqsy equilibrates a symmetric matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqsy(UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void slaqsy_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, const float *s, const float *scond,
             const float *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if EQUED = 'Y', the equilibrated matrix: diag(S) * A * diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

S Input parameter.

S is REAL

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is REAL

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqsy*, *dlaqsy* and *zlaqsy*.

4.17.515 slaqtr

slaqtr solves the real quasi-triangular system

```
op(T)*p = scale*c,                 if LREAL = .TRUE.
```

or the complex quasi-triangular systems

```
op(T + iB)*(p+iq) = scale*(c+id),  if LREAL = .FALSE.
```

in real arithmetic, where T is upper quasi-triangular. If LREAL = .FALSE., then the first diagonal block of T must be 1 by 1, B is the specially structured matrix

```
B = [ b(1) b(2) ... b(n) ]
    [       w            ]
    [           w        ]
    [               .    ]
    [                   w ]
```

op(A) = A or A^T , A^T denotes the transpose of matrix A.

On input, X = [c]. On output, X = [p].

```
[ d ]                  [ q ]
```

This subroutine is designed for the condition number estimation in routine STRSNA.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaqtr(LTRAN, LREAL, N, T, LDT, B, W, SCALE, X, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void slaqtr_(const armpl_int_t *ltran, const armpl_int_t *lreal,
             const armpl_int_t *n, const float *t, const armpl_int_t *ldt,
             const float *b, const float *w, float *scale, float *x,
             float *work, armpl_int_t *info);
```

Parameters

LTRAN Input parameter.

LTRAN is LOGICAL

On entry, LTRAN specifies the option of conjugate transpose: = .FALSE., op(T+i*B) = T+i*B, = .TRUE., op(T+i*B) = $(T+i*B)^T$.

LREAL Input parameter.

L‘‘REAL‘‘ is LOGICAL

On entry, L‘‘REAL‘‘ specifies the input matrix structure: = .FALSE., the input is complex = .TRUE., the input is real

N Input parameter.

N is INTEGER

On entry, N specifies the order of T+i*B. N >= 0.

T Input parameter.

T is REAL

T is an array, dimension (LDT, N). On entry, T contains a matrix in Schur canonical form. If L‘‘REAL‘‘ = .FALSE., then the first diagonal block of T must be 1 by 1.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the matrix T. LDT >= max(1, N).

B Input parameter.

B is REAL

B is an array, dimension (N). On entry, B contains the elements to form the matrix B as described above. If L‘‘REAL‘‘ = .TRUE., B is not referenced.

W Input parameter.

W is REAL

On entry, W is the diagonal element of the matrix B. If L‘‘REAL‘‘ = .TRUE., W is not referenced.

SCALE Output parameter.

SCALE is REAL

On exit, SCALE is the scale factor.

X Input and output parameter.

X is REAL

X is an array, dimension (2*N). On entry, X contains the right hand side of the system. On exit, X is overwritten by the solution.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

On exit, INFO is set to 0: successful exit. 1: the some diagonal 1 by 1 block has been perturbed by a small number SMIN to keep nonsingularity. 2: the some diagonal 2 by 2 block has been perturbed by a small

number in SLALN2 to keep nonsingularity. NOTE: In the interests of speed, this routine does not check the inputs for errors.

Related Information

For this routine in other precisions, please see *dlaqtr*.

4.17.516 slar1v

`slar1v` computes the (scaled) r-th column of the inverse of the sumbmatrix in rows B1 through BN of the tridiagonal matrix L D L^T - sigma I. When sigma is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, r corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation : (a) Stationary qd transform, L D L^T - sigma I = L(+) D(+) $L(+)^T$, (b) Progressive qd transform, L D L^T - sigma I = U(-) D(-) $U(-)^T$, (c) Computation of the diagonal elements of the inverse of

```
L D L**T - sigma I by combining the above transforms, and choosing
r as the index where the diagonal of the inverse is (one of the)
largest in magnitude.
```

(d) Computation of the (scaled) r-th column of the inverse using the

```
twisted factorization obtained by combining the top part of the
the stationary and the bottom part of the progressive transform.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slar1v(N, B1, BN, LAMBDA, D, L, LD, LLD, PIVMIN, GAPTOL, Z, WANTNC,
                  NEGCNT, ZTZ, MINGMA, R, ISUPPZ, NRMINV, RESID, RQCORR,
                  WORK)
```

C specification:

```
#include "armpl.h"

void slar1v_(const armpl_int_t *n, const armpl_int_t *b1,
             const armpl_int_t *bn, const float *lambda, const float *d,
             const float *l, const float *ld, const float *lld,
             const float *pivmin, const float *gaptol, float *z,
             const armpl_int_t *wantnc, armpl_int_t *negcnt, float *ztz,
             float *mingma, armpl_int_t *r, armpl_int_t *isuppz,
             float *nrminv, float *resid, float *rqcorr, float *work);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The order of the matrix `L D` L^T .

B1 Input parameter.

`B1` is `INTEGER`

First index of the submatrix of `L D` L^T .

BN Input parameter.

BN is INTEGER

Last index of the submatrix of L D L^T .

LAMBDA Input parameter.

LAMBDA is REAL

The shift. In order to compute an accurate eigenvector, LAMBDA should be a good approximation to an eigenvalue of L D L^T .

L Input parameter.

L is REAL

L is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal matrix L, in elements 1 to N-1.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D.

LD Input parameter.

LD is REAL

LD is an array, dimension (N-1). The n-1 elements L(i)*D(i).

LLD Input parameter.

LLD is REAL

LLD is an array, dimension (N-1). The n-1 elements L(i)*L(i)*D(i).

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot in the Sturm sequence.

GAPTOL Input parameter.

GAPTOL is REAL

Tolerance that indicates when eigenvector entries are negligible w.r.t. their contribution to the residual.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (N). On input, all entries of Z must be set to 0. On output, Z contains the (scaled) r-th column of the inverse. The scaling is such that Z(R) equals 1.

WANTNC Input parameter.

WANTNC is LOGICAL

Specifies whether NEGCNT has to be computed.

NEGCNT Output parameter.

NEGCNT is INTEGER

If WANTNC is .TRUE. then NEGCNT = the number of pivots < pivmin in the matrix factorization L D L^T , and NEGCNT = -1 otherwise.

ZTZ Output parameter.

ZTZ is REAL

The square of the 2-norm of Z.

MINGMA Output parameter.

MINGMA is REAL

The reciprocal of the largest (in magnitude) diagonal element of the inverse of L D L^T - sigma I.

R Input and output parameter.

R is INTEGER

The twist index for the twisted factorization used to compute Z. On input, 0 <= R <= N. If R is input as 0, R is set to the index where (L D L^T - sigma I)^{-1} is largest in magnitude. If 1 <= R <= N, R is unchanged. On output, R contains the twist index used to compute Z. Ideally, R designates the position of the maximum entry in the eigenvector.

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2)

The support of the vector in Z, i.e., the vector Z is nonzero only in elements ISUPPZ(1) through ISUPPZ(2).

NRMINV Output parameter.

NRMINV is REAL

NRMINV = 1/SQRT(ZTZ)

RESID Output parameter.

RESID is REAL

The residual of the FP vector. RESID = ABS(MINGMA)/SQRT(ZTZ)

RQCORR Output parameter.

RQCORR is REAL

The Rayleigh Quotient correction to LAMBDA. RQCORR = MINGMA*TMP

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

Related Information

For this routine in other precisions, please see *clar1v*, *dlar1v* and *zlar1v*.

4.17.517 slar2v

slar2v applies a vector of real plane rotations from both sides to a sequence of 2-by-2 real symmetric matrices, defined by the elements of the vectors x, y and z. For i = 1,2,...,n

```
( x(i)  z(i) ) := (  c(i)  s(i) ) ( x(i)  z(i) ) ( c(i) -s(i) )
( z(i)  y(i) )    ( -s(i)  c(i) ) ( z(i)  y(i) ) ( s(i)  c(i) )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slar2v(N, X, Y, Z, INCX, C, S, INCC)
```

C specification:

```
#include "armpl.h"

void slar2v_(const armpl_int_t *n, float *x, float *y, float *z,
             const armpl_int_t *incx, const float *c, const float *s,
             const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be applied.

X Input and output parameter.

X is REAL

X is an array,. dimension (1+(N-1)*INCX) The vector x.

Y Input and output parameter.

Y is REAL

Y is an array,. dimension (1+(N-1)*INCX) The vector y.

Z Input and output parameter.

Z is REAL

Z is an array,. dimension (1+(N-1)*INCX) The vector z.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X, Y and Z. INCX > 0.

C Input parameter.

C is REAL

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

S Input parameter.

S is REAL

S is an array, dimension (1+(N-1)*INCC). The sines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C and S. INCC > 0.

Related Information

For this routine in other precisions, please see *clar2v*, *dlar2v* and *zlar2v*.

4.17.518 slarf

slarf applies a real elementary reflector H to a real m by n matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**T
```

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarf(SIDE, M, N, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void slarf_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
            const float *v, const armpl_int_t *incv, const float *tau,
            float *c, const armpl_int_t *ldc, float *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

V Input parameter.

V is REAL

V is an array, dimension. (1 + (M-1)*abs(INCV)) if SIDE = 'L' or (1 + (N-1)*abs(INCV)) if SIDE = 'R' The vector v in the representation of H. V is not used if TAU = 0.

INCV Input parameter.

INCV is INTEGER

The increment between elements of v. INCV <> 0.

TAU Input parameter.

TAU is REAL

The value tau in the representation of H.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R'

Related Information

For this routine in other precisions, please see *clarf*, *dlarf* and *zlarf*.

4.17.519 slarfb

slarfb applies a real block reflector H or its transpose H^T to a real m by n matrix C, from either the left or the right.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarfb(SIDE, TRANS, DIRECT, STOREV, M, N, K, V, LDV, T, LDT, C,
                  LDC, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void slarfb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const float *v, const armpl_int_t *ldv,
             const float *t, const armpl_int_t *ldt, float *c,
             const armpl_int_t *ldc, float *work, const armpl_int_t *ldwork,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^T from the Left = 'R': apply H or H^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'T': apply H^T (Transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columnwise = 'R': Rowwise

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

K Input parameter.

K is INTEGER

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

V Input parameter.

V is REAL

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, M) if STOREV = 'R' and SIDE = 'L' (LDV, N) if STOREV = 'R' and SIDE = 'R' The matrix V. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C' and SIDE = 'L', LDV >= max(1, M); if STOREV = 'C' and SIDE = 'R', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

T Input parameter.

T is REAL

T is an array, dimension (LDT, K). The triangular k by k matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by H* C or H^T * C or C*H or C*H^T .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LDWORK, K) .

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1, N); if SIDE = 'R', LDWORK >= max(1, M).

Related Information

For this routine in other precisions, please see *clarfb*, *dlarfb* and *zlarfb*. It also exists with a native C interface as *LAPACKE_slarfb*.

4.17.520 slarfg

`slarfg` generates a real elementary reflector H of order n, such that

```
H * ( alpha ) = ( beta ),   H**T * H = I.
    (   x   )   (   0  )
```

where alpha and beta are scalars, and x is an (n-1)-element real vector. H is represented in the form

```
H = I - tau * ( 1 ) * ( 1 v**T ) ,
              ( v )
```

where tau is a real scalar and v is a real (n-1)-element vector.

If the elements of x are all zero, then tau = 0 and H is taken to be the unit matrix.

Otherwise 1 <= tau <= 2.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarfg(N, ALPHA, X, INCX, TAU)
```

C specification:

```
#include "armpl.h"

void slarfg_(const armpl_int_t *n, float *alpha, float *x,
             const armpl_int_t *incx, float *tau);
```

Parameters

N Input parameter.

N is INTEGER

The order of the elementary reflector.

ALPHA Input and output parameter.

ALPHA is REAL

On entry, the value alpha. On exit, it is overwritten with the value beta.

X Input and output parameter.

X is REAL

X is an array, dimension. (1+(N-2)*abs(INCX)) On entry, the vector x. On exit, it is overwritten with the vector v.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

TAU Output parameter.

TAU is REAL

The value tau.

Related Information

For this routine in other precisions, please see *clarfg*, *dlarfg* and *zlarfg*. It also exists with a native C interface as *LAPACKE_slarfg*.

4.17.521 slarfgp

slarfgp generates a real elementary reflector H of order n, such that

```
H * ( alpha ) = ( beta ),   H**T * H = I.
    (   x   )   (   0  )
```

where alpha and beta are scalars, beta is non-negative, and x is an (n-1)-element real vector. H is represented in the form

```
H = I - tau * ( 1 ) * ( 1 v**T ) ,
              ( v )
```

where tau is a real scalar and v is a real (n-1)-element vector.

If the elements of x are all zero, then tau = 0 and H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarfgp(N, ALPHA, X, INCX, TAU)
```

C specification:

```
#include "armpl.h"

void slarfgp_(const armpl_int_t *n, float *alpha, float *x,
              const armpl_int_t *incx, float *tau);
```

Parameters

N Input parameter.

N is INTEGER

The order of the elementary reflector.

ALPHA Input and output parameter.

ALPHA is REAL

On entry, the value alpha. On exit, it is overwritten with the value beta.

X Input and output parameter.

X is REAL

X is an array, dimension. (1+(N-2)*abs(INCX)) On entry, the vector x. On exit, it is overwritten with the vector v.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

TAU Output parameter.

TAU is REAL

The value tau.

Related Information

For this routine in other precisions, please see *clarfgp*, *dlarfgp* and *zlarfgp*.

4.17.522 slarft

slarft forms the triangular factor T of a real block reflector H of order n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

```
H  =  I - V * T * V**T
```

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

```
H  =  I - V**T * T * V
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slarft(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

C specification:

```
#include "armpl.h"

void slarft_(const char *direct, const char *storev, const armpl_int_t *n,
             const armpl_int_t *k, const float *v, const armpl_int_t *ldv,
             const float *tau, float *t, const armpl_int_t *ldt, ... );
```

Parameters

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details): = 'C': columnwise = 'R': rowwise

N Input parameter.

N is INTEGER

The order of the block reflector H. N >= 0.

K Input parameter.

K is INTEGER

The order of the triangular factor T (= the number of elementary reflectors). K >= 1.

V Input parameter.

V is REAL

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, N) if STOREV = 'R' The matrix V. See further details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i).

T Output parameter.

T is REAL

T is an array, dimension (LDT, K). The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

Related Information

For this routine in other precisions, please see *clarft*, *dlarft* and *zlarft*. It also exists with a native C interface as *LAPACKE_slarft*.

4.17.523 slarfx

slarfx applies a real elementary reflector H to a real m by n matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**T
```

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix

This version uses inline code if H has order < 11.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarfx(SIDE, M, N, V, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void slarfx_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
             const float *v, const float *tau, float *c,
             const armpl_int_t *ldc, float *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

V Input parameter.

V is REAL

V is an array, dimension (M) if SIDE = 'L'. or (N) if SIDE = 'R' The vector v in the representation of H.

TAU Input parameter.

TAU is REAL

The value tau in the representation of H.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDA >= (1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R' WORK is not referenced if H has order < 11.

Related Information

For this routine in other precisions, please see *clarfx*, *dlarfx* and *zlarfx*. It also exists with a native C interface as *LAPACKE_slarfx*.

4.17.524 slarfy

`slarfy` applies an elementary reflector, or Householder matrix, H, to an n x n symmetric matrix C, from both the left and the right.

H is represented in the form

```
H = I - tau * v * v'
```

where tau is a scalar and v is a vector.

If tau is zero, then H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarfy(UPLO, N, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void slarfy_(const char *uplo, const armpl_int_t *n, const float *v,
             const armpl_int_t *incv, const float *tau, float *c,
             const armpl_int_t *ldc, float *work, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the upper or lower triangular part of the symmetric matrix `C` is stored. = '`U`': Upper triangle = '`L`': Lower triangle

N Input parameter.

`N` is `INTEGER`

The number of rows and columns of the matrix `C`. `N` >= 0.

V Input parameter.

`V` is `REAL`

`V` is an array, dimension. (1 + (N-1)*abs(`INCV`)) The vector v as described above.

INCV Input parameter.

`INCV` is `INTEGER`

The increment between successive elements of v. `INCV` must not be zero.

TAU Input parameter.

TAU is REAL

The value tau as described above.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the matrix C. On exit, C is overwritten by H * C * H'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

Related Information

For this routine in other precisions, please see *clarfy*, *dlarfy* and *zlarfy*.

4.17.525 slargv

slargv generates a vector of real plane rotations, determined by elements of the real vectors x and y. For i = 1,2,...,n

```
(  c(i)  s(i) ) ( x(i) ) = ( a(i) )
( -s(i)  c(i) ) ( y(i) ) = (   0  )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slargv(N, X, INCX, Y, INCY, C, INCC)
```

C specification:

```
#include "armpl.h"

void slargv_(const armpl_int_t *n, float *x, const armpl_int_t *incx,
             float *y, const armpl_int_t *incy, float *c,
             const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be generated.

X Input and output parameter.

X is REAL

X is an array,. dimension (1+(N-1)*INCX) On entry, the vector x. On exit, x(i) is overwritten by a(i), for i = 1,. . . ,n.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

Y Input and output parameter.

Y is REAL

Y is an array,. dimension (1+(N-1)*INCY) On entry, the vector y. On exit, the sines of the plane rotations.

INCY Input parameter.

INCY is INTEGER

The increment between elements of Y. INCY > 0.

C Output parameter.

C is REAL

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C. INCC > 0.

Related Information

For this routine in other precisions, please see *clargv*, *dlargv* and *zlargv*.

4.17.526 slarnv

slarnv returns a vector of n random real numbers from a uniform or normal distribution.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarnv(IDIST, ISEED, N, X)
```

C specification:

```
#include "armpl.h"

void slarnv_(const armpl_int_t *idist, armpl_int_t *iseed,
             const armpl_int_t *n, float *x);
```

Parameters

IDIST Input parameter.

IDIST is INTEGER

Specifies the distribution of the random numbers: = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1)

ISEED Input and output parameter.

ISEED is INTEGER array, dimension (4)

On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and ISEED(4) must be odd. On exit, the seed is updated.

N Input parameter.

N is INTEGER

The number of random numbers to be generated.

X Output parameter.

X is REAL

X is an array, dimension (N). The generated random numbers.

Related Information

For this routine in other precisions, please see *clarnv*, *dlarnv* and *zlarnv*. It also exists with a native C interface as *LAPACKE_slarnv*.

4.17.527 slarra

Compute the splitting points with threshold SPLTOL. slarra sets any "small" off-diagonal elements to zero.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarra(N, D, E, E2, SPLTOL, TNRM, NSPLIT, ISPLIT, INFO)
```

C specification:

```
#include "armpl.h"

void slarra_(const armpl_int_t *n, const float *d, float *e, float *e2,
             const float *spltol, const float *tnrm, armpl_int_t *nsplit,
             armpl_int_t *isplit, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N > 0.

D Input parameter.

D is REAL

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T.

E Input and output parameter.

E is REAL

E is an array, dimension (N). On entry, the first (N-1) entries contain the subdiagonal elements of the tridiagonal matrix T; E(N) need not be set. On exit, the entries E(ISPLIT(I)), 1 <= I <= NSPLIT, are set to zero, the other entries of E are untouched.

E2 Input and output parameter.

E2 is REAL

E2 is an array, dimension (N). On entry, the first (N-1) entries contain the SQUARES of the subdiagonal elements of the tridiagonal matrix T; E2(N) need not be set. On exit, the entries E2(ISPLIT(I)), 1 <= I <= NSPLIT, have been set to zero

SPLTOL Input parameter.

SPLTOL is REAL

The threshold for splitting. Two criteria can be used: SPLTOL<0 : criterion based on absolute off-diagonal value SPLTOL>0 : criterion that preserves relative accuracy

TNRM Input parameter.

TNRM is REAL

The norm of the matrix.

NSPLIT Output parameter.

NSPLIT is INTEGER

The number of blocks T splits into. 1 <= NSPLIT <= N.

ISPLIT Output parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

Related Information

For this routine in other precisions, please see *dlarra*.

4.17.528 slarrb

Given the relatively robust representation(RRR) L D L^T, slarrb does "limited" bisection to refine the eigenvalues of L D L^T, W(IFIRST-OFFSET) through W(ILAST-OFFSET), to more accuracy. Initial guesses for these eigenvalues are input in W, the corresponding estimate of the error in these guesses and their gaps are input in WERR and WGAP, respectively. During bisection, intervals [left, right] are maintained by storing their mid-points and semi-widths in the arrays W and WERR respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarrb(N, D, LLD, IFIRST, ILAST, RTOL1, RTOL2, OFFSET, W, WGAP,
                  WERR, WORK, IWORK, PIVMIN, SPDIAM, TWIST, INFO)
```

C specification:

```
#include "armpl.h"

void slarrb_(const armpl_int_t *n, const float *d, const float *lld,
             const armpl_int_t *ifirst, const armpl_int_t *ilast,
             const float *rtol1, const float *rtol2,
             const armpl_int_t *offset, float *w, float *wgap, float *werr,
             float *work, armpl_int_t *iwork, const float *pivmin,
             const float *spdiam, const armpl_int_t *twist,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix.

D Input parameter.

D is REAL

D is an array, dimension (N). The N diagonal elements of the diagonal matrix D.

LLD Input parameter.

LLD is REAL

LLD is an array, dimension (N-1). The (N-1) elements L(i)*L(i)*D(i).

IFIRST Input parameter.

IFIRST is INTEGER

The index of the first eigenvalue to be computed.

ILAST Input parameter.

ILAST is INTEGER

The index of the last eigenvalue to be computed.

RTOL1 Input parameter.

RTOL1 is REAL

RTOL2 Input parameter.

RTOL2 is REAL

Tolerance for the convergence of the bisection intervals. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|)) where GAP is the (estimated) distance to the nearest eigenvalue.

OFFSET Input parameter.

OFFSET is INTEGER

Offset for the arrays W, WGAP and WERR, i.e., the IFIRST-OFFSET through ILAST-OFFSET elements of these arrays are to be used.

W Input and output parameter.

W is REAL

W is an array, dimension (N). On input, W(IFIRST-OFFSET) through W(ILAST-OFFSET) are estimates of the eigenvalues of L D L^T indexed IFIRST through ILAST. On output, these estimates are refined.

WGAP Input and output parameter.

WGAP is REAL

WGAP is an array, dimension (N-1). On input, the (estimated) gaps between consecutive eigenvalues of L D L^T, i.e., WGAP(I-OFFSET) is the gap between eigenvalues I and I+1. Note that if IFIRST.EQ.ILAST then WGAP(IFIRST-OFFSET) must be set to ZERO. On output, these gaps are refined.

WERR Input and output parameter.

WERR is REAL

WERR is an array, dimension (N). On input, WERR(IFIRST-OFFSET) through WERR(ILAST-OFFSET) are the errors in the estimates of the corresponding elements in W. On output, these errors are refined.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N). Workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (2*N)

Workspace.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot in the Sturm sequence.

SPDIAM Input parameter.

SPDIAM is REAL

The spectral diameter of the matrix.

TWIST Input parameter.

TWIST is INTEGER

The twist index for the twisted factorization that is used for the negcount. TWIST = N: Compute negcount from L D L^T - LAMBDA I = L+ D+ L+^T TWIST = 1: Compute negcount from L D L^T - LAMBDA I = U- D- U-^T TWIST = R: Compute negcount from L D L^T - LAMBDA I = N(r) D(r) N(r)

INFO Output parameter.

INFO is INTEGER

Error flag.

Related Information

For this routine in other precisions, please see *dlarrb*.

4.17.529 slarrc

Find the number of eigenvalues of the symmetric tridiagonal matrix T that are in the interval (VL,VU] if JOBT = 'T', and of L D L^T if JOBT = 'L'.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarrc(JOBT, N, VL, VU, D, E, PIVMIN, EIGCNT, LCNT, RCNT, INFO)
```

C specification:

```
#include "armpl.h"

void slarrc_(const char *jobt, const armpl_int_t *n, const float *vl,
             const float *vu, const float *d, const float *e,
             const float *pivmin, armpl_int_t *eigcnt, armpl_int_t *lcnt,
             armpl_int_t *rcnt, armpl_int_t *info, ... );
```

Parameters

JOBT Input parameter.

JOBT is CHARACTER*1

= 'T': Compute Sturm count for matrix T. = 'L': Compute Sturm count for matrix L D L^T.

N Input parameter.

N is INTEGER

The order of the matrix. N > 0.

VL Input parameter.

VL is REAL

The lower bound for the eigenvalues.

VU Input parameter.

VU is REAL

The upper bound for the eigenvalues.

D Input parameter.

D is REAL

D is an array, dimension (N). JOBT = 'T': The N diagonal elements of the tridiagonal matrix T. JOBT = 'L': The N diagonal elements of the diagonal matrix D.

E Input parameter.

E is REAL

E is an array, dimension (N). JOBT = 'T': The N-1 offdiagonal elements of the matrix T. JOBT = 'L': The N-1 offdiagonal elements of the matrix L.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot in the Sturm sequence for T.

EIGCNT Output parameter.

EIGCNT is INTEGER

The number of eigenvalues of the symmetric tridiagonal matrix T that are in the interval (VL,VU]

LCNT Output parameter.

LCNT is INTEGER

RCNT Output parameter.

RCNT is INTEGER

The left and right negcounts of the interval.

INFO Output parameter.

INFO is INTEGER

Related Information

For this routine in other precisions, please see *dlarrc*.

4.17.530 slarrd

slarrd computes the eigenvalues of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from SSTEMR. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarrd(RANGE, ORDER, N, VL, VU, IL, IU, GERS, RELTOL, D, E, E2,
                  PIVMIN, NSPLIT, ISPLIT, M, W, WERR, WL, WU, IBLOCK, INDEXW,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slarrd_(const char *range, const char *order, const armpl_int_t *n,
             const float *vl, const float *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const float *gers, const float *reltol,
             const float *d, const float *e, const float *e2,
             const float *pivmin, const armpl_int_t *nsplit,
             const armpl_int_t *isplit, armpl_int_t *m, float *w, float *werr,
             float *wl, float *wu, armpl_int_t *iblock, armpl_int_t *indexw,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found. = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

ORDER Input parameter.

ORDER is CHARACTER*1

= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see IBLOCK, ISPLIT) and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix T. N >= 0.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

GERS Input parameter.

GERS is REAL

GERS is an array, dimension (2*N). The N Gerschgorin intervals (the i-th Gerschgorin interval is (GERS(2*i-1), GERS(2*i)).

RELTOL Input parameter.

RELTOL is REAL

The minimum relative width of an interval. When an interval is narrower than RELTOL times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the tridiagonal matrix T.

E2 Input parameter.

E2 is REAL

E2 is an array, dimension (N-1). The (n-1) squared off-diagonal elements of the tridiagonal matrix T.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot allowed in the Sturm sequence for T.

NSPLIT Input parameter.

NSPLIT is INTEGER

The number of diagonal blocks in the matrix T. 1 <= NSPLIT <= N.

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N. (Only the first NSPLIT elements will actually be used, but since the user cannot know a priori what value NSPLIT will have, N words must be reserved for ISPLIT.)

M Output parameter.

M is INTEGER

The actual number of eigenvalues found. 0 <= M <= N. (See also the description of INFO=2,3.)

W Output parameter.

W is REAL

W is an array, dimension (N). On exit, the first M elements of W will contain the eigenvalue approximations. SLARRD computes an interval I_j = (a_j, b_j] that includes eigenvalue j. The eigenvalue approximation is given as the interval midpoint W(j)= (a_j + b_j)/2. The corresponding error is bounded by WERR(j) = abs(a_j - b_j)/2

WERR Output parameter.

WERR is REAL

WERR is an array, dimension (N). The error bound on the corresponding eigenvalue approximation in W.

WL Output parameter.

WL is REAL

WU Output parameter.

WU is REAL

The interval (WL, WU] contains all the wanted eigenvalues. If RANGE='V', then WL=VL and WU=VU. If RANGE='A', then WL and WU are the global Gerschgorin bounds on the spectrum. If RANGE='I', then WL and WU are computed by SLAEBZ from the index range specified.

IBLOCK Output parameter.

IBLOCK is INTEGER array, dimension (N)

At each row/column j where E(j) is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if INFO = 0, IBLOCK(i) specifies to which block (from 1 to the number of blocks) the eigenvalue W(i) belongs. (SLARRD may use the remaining N-M elements as workspace.)

INDEXW Output parameter.

INDEXW is INTEGER array, dimension (N)

The indices of the eigenvalues within each block (submatrix); for example, INDEXW(i)= j and IBLOCK(i)=k imply that the i-th eigenvalue W(i) is the j-th eigenvalue in block k.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (3*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: some or all of the eigenvalues failed to converge or were not computed: =1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. This is generally caused by unexpectedly inaccurate arithmetic. =2 or 3: RANGE='I' only: Not all of the eigenvalues IL:IU were found. Effect: M < IU+1-IL Cause: non-monotonic arithmetic, causing the Sturm sequence to be non-monotonic. Cure: recalculate, using RANGE='A', and pick out eigenvalues IL:IU. In some cases, increasing the PARAMETER "FUDGE" may make things work. = 4: RANGE='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed. Probable cause: your machine has sloppy floating-point arithmetic. Cure: Increase the PARAMETER "FUDGE", recompile, and try again.

Related Information

For this routine in other precisions, please see *dlarrd*.

4.17.531 slarre

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T, slarre sets any "small" off-diagonal elements to zero, and for each unreduced block T_i, it finds (a) a suitable shift at one end of the block's spectrum, (b) the base representation, T_i - sigma_i I = L_i D_i L_i^T, and (c) eigenvalues of each L_i D_i L_i^T. The representations and eigenvalues found are then used by SSTEMR to compute the eigenvectors of T. The accuracy varies depending on whether bisection is used to find a few eigenvalues or the dqds algorithm (subroutine SLASQ2) to conpute all and then discard any unwanted one. As an added benefit, slarre also outputs the n Gerschgorin intervals for the matrices L_i D_i L_i^T.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarre(RANGE, N, VL, VU, IL, IU, D, E, E2, RTOL1, RTOL2, SPLTOL,
                  NSPLIT, ISPLIT, M, W, WERR, WGAP, IBLOCK, INDEXW, GERS,
                  PIVMIN, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slarre_(const char *range, const armpl_int_t *n, float *vl, float *vu,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *il, const armpl_int_t *iu, float *d, float *e,
                float *e2, const float *rtol1, const float *rtol2,
                const float *spltol, armpl_int_t *nsplit, armpl_int_t *isplit,
                armpl_int_t *m, float *w, float *werr, float *wgap,
                armpl_int_t *iblock, armpl_int_t *indexw, float *gers,
                float *pivmin, float *work, armpl_int_t *iwork,
                armpl_int_t *info, ... );
```

Parameters

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found. = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

N Input parameter.

N is INTEGER

The order of the matrix. N > 0.

VL Input and output parameter.

VL is REAL

If RANGE='V', the lower bound for the eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. If RANGE='I' or ='A', SLARRE computes bounds on the desired part of the spectrum.

VU Input and output parameter.

VU is REAL

If RANGE='V', the upper bound for the eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. If RANGE='I' or ='A', SLARRE computes bounds on the desired part of the spectrum.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the N diagonal elements of the tridiagonal matrix T. On exit, the N diagonal elements of the diagonal matrices D_i.

E Input and output parameter.

E is REAL

E is an array, dimension (N). On entry, the first (N-1) entries contain the subdiagonal elements of the tridiagonal matrix T; E(N) need not be set. On exit, E contains the subdiagonal elements of the unit bidiagonal matrices L_i. The entries E(ISPLIT(I)), 1 <= I <= NSPLIT, contain the base points sigma_i on output.

E2 Input and output parameter.

E2 is REAL

E2 is an array, dimension (N). On entry, the first (N-1) entries contain the SQUARES of the subdiagonal elements of the tridiagonal matrix T; E2(N) need not be set. On exit, the entries E2(ISPLIT(I)), 1 <= I <= NSPLIT, have been set to zero

RTOL1 Input parameter.

RTOL1 is REAL

RTOL2 Input parameter.

RTOL2 is REAL

Parameters for bisection. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|))

SPLTOL Input parameter.

SPLTOL is REAL

The threshold for splitting.

NSPLIT Output parameter.

NSPLIT is INTEGER

The number of blocks T splits into. 1 <= NSPLIT <= N.

ISPLIT Output parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.

M Output parameter.

M is INTEGER

The total number of eigenvalues (of all L_i D_i L_i^T) found.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the eigenvalues. The eigenvalues of each of the blocks, L_i D_i L_i^T, are sorted in ascending order (SLARRE may use the remaining N-M elements as workspace).

WERR Output parameter.

WERR is REAL

WERR is an array, dimension (N). The error bound on the corresponding eigenvalue in W.

WGAP Output parameter.

WGAP is REAL

WGAP is an array, dimension (N). The separation from the right neighbor eigenvalue in W. The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree. Exception: at the right end of a block we store the left gap

IBLOCK Output parameter.

IBLOCK is INTEGER array, dimension (N)

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first block from the top, =2 if W(i) belongs to the second block, etc.

INDEXW Output parameter.

INDEXW is INTEGER array, dimension (N)

The indices of the eigenvalues within each block (submatrix); for example, INDEXW(i)= 10 and IBLOCK(i)=2 imply that the i-th eigenvalue W(i) is the 10-th eigenvalue in block 2

GERS Output parameter.

GERS is REAL

GERS is an array, dimension (2*N). The N Gerschgorin intervals (the i-th Gerschgorin interval is (GERS(2*i-1), GERS(2*i)).

PIVMIN Output parameter.

PIVMIN is REAL

The minimum pivot in the Sturm sequence for T.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (6*N). Workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

Workspace.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: A problem occurred in SLARRE. < 0: One of the called subroutines signaled an internal problem. Needs inspection of the corresponding parameter IINFO for further information.

=-1: Problem in SLARRD. = 2: No base representation could be found in MAXTRY iterations. Increasing MAXTRY and recompilation might be a remedy. =-3: Problem in SLARRB when computing the refined root representation for SLASQ2. =-4: Problem in SLARRB when preforming bisection on the desired part of the spectrum. =-5: Problem in SLASQ2. =-6: Problem in SLASQ2.

Related Information

For this routine in other precisions, please see *dlarre*.

4.17.532 slarrf

Given the initial representation L D L^T and its cluster of close eigenvalues (in a relative measure), W(CLSTRT), W(CLSTRT+1), ... W(CLEND), `slarrf` finds a new relatively robust representation L D L^T - SIGMA I = L(+) D(+) L(+)^T such that at least one of the eigenvalues of L(+) D(+) L(+)^T is relatively isolated.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarrf(N, D, L, LD, CLSTRT, CLEND, W, WGAP, WERR, SPDIAM, CLGAPL,
                  CLGAPR, PIVMIN, SIGMA, DPLUS, LPLUS, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void slarrf_(const armpl_int_t *n, const float *d, const float *l,
             const float *ld, const armpl_int_t *clstrt,
             const armpl_int_t *clend, const float *w, float *wgap,
             const float *werr, const float *spdiam, const float *clgapl,
             float *clgapr, const float *pivmin, float *sigma, float *dplus,
             float *lplus, float *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix (subblock, if the matrix split).

D Input parameter.

D is REAL

D is an array, dimension (N). The N diagonal elements of the diagonal matrix D.

L Input parameter.

L is REAL

L is an array, dimension (N-1). The (N-1) subdiagonal elements of the unit bidiagonal matrix L.

LD Input parameter.

LD is REAL

LD is an array, dimension (N-1). The (N-1) elements L(i)*D(i).

CLSTRT Input parameter.

CLSTRT is INTEGER

The index of the first eigenvalue in the cluster.

CLEND Input parameter.

CLEND is INTEGER

The index of the last eigenvalue in the cluster.

W Input parameter.

W is REAL

W is an array, dimension. dimension is >= (CLEND-CLSTRT+1) The eigenvalue APPROXIMATIONS of L D L^T in ascending order. W(CLSTRT) through W(CLEND) form the cluster of relatively close eigenalues.

WGAP Input and output parameter.

WGAP is REAL

WGAP is an array, dimension. dimension is >= (CLEND-CLSTRT+1) The separation from the right neighbor eigenvalue in W.

WERR Input parameter.

WERR is REAL

WERR is an array, dimension. dimension is >= (CLEND-CLSTRT+1) WERR contain the semiwidth of the uncertainty interval of the corresponding eigenvalue APPROXIMATION in W

SPDIAM Input parameter.

SPDIAM is REAL

estimate of the spectral diameter obtained from the Gerschgorin intervals

CLGAPL Input parameter.

CLGAPL is REAL

CLGAPR Input parameter.

CLGAPR is REAL

absolute gap on each end of the cluster. Set by the calling routine to protect against shifts too close to eigenvalues outside the cluster.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot allowed in the Sturm sequence.

SIGMA Output parameter.

SIGMA is REAL

The shift used to form L(+) D(+) L(+)^T.

DPLUS Output parameter.

DPLUS is REAL

DPLUS is an array, dimension (N). The N diagonal elements of the diagonal matrix D(+).

LPLUS Output parameter.

LPLUS is REAL

LPLUS is an array, dimension (N-1). The first (N-1) elements of LPLUS contain the subdiagonal elements of the unit bidiagonal matrix L(+).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N). Workspace.

INFO Output parameter.

INFO is INTEGER

Signals processing OK (=0) or failure (=1)

Related Information

For this routine in other precisions, please see *dlarrf*.

4.17.533 slarrj

Given the initial eigenvalue approximations of T, slarrj does bisection to refine the eigenvalues of T, W(IFIRST-OFFSET) through W(ILAST-OFFSET), to more accuracy. Initial guesses for these eigenvalues are input in W, the corresponding estimate of the error in these guesses in WERR. During bisection, intervals [left, right] are maintained by storing their mid-points and semi-widths in the arrays W and WERR respectively.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarrj(N, D, E2, IFIRST, ILAST, RTOL, OFFSET, W, WERR, WORK, IWORK,
                  PIVMIN, SPDIAM, INFO)
```

C specification:

```
#include "armpl.h"

void slarrj_(const armpl_int_t *n, const float *d, const float *e2,
             const armpl_int_t *ifirst, const armpl_int_t *ilast,
             const float *rtol, const armpl_int_t *offset, float *w,
             float *werr, float *work, armpl_int_t *iwork,
             const float *pivmin, const float *spdiam, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix.

D Input parameter.

D is REAL

D is an array, dimension (N). The N diagonal elements of T.

E2 Input parameter.

E2 is REAL

E2 is an array, dimension (N-1). The Squares of the (N-1) subdiagonal elements of T.

IFIRST Input parameter.

IFIRST is INTEGER

The index of the first eigenvalue to be computed.

ILAST Input parameter.

ILAST is INTEGER

The index of the last eigenvalue to be computed.

RTOL Input parameter.

RTOL is REAL

Tolerance for the convergence of the bisection intervals. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.RTOL*MAX(|LEFT|,|RIGHT|).

OFFSET Input parameter.

OFFSET is INTEGER

Offset for the arrays W and WERR, i.e., the IFIRST-OFFSET through ILAST-OFFSET elements of these arrays are to be used.

W Input and output parameter.

W is REAL

W is an array, dimension (N). On input, W(IFIRST-OFFSET) through W(ILAST-OFFSET) are estimates of the eigenvalues of L D L^T indexed IFIRST through ILAST. On output, these estimates are refined.

WERR Input and output parameter.

WERR is REAL

WERR is an array, dimension (N). On input, WERR(IFIRST-OFFSET) through WERR(ILAST-OFFSET) are the errors in the estimates of the corresponding elements in W. On output, these errors are refined.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N). Workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (2*N)

Workspace.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot in the Sturm sequence for T.

SPDIAM Input parameter.

SPDIAM is REAL

The spectral diameter of T.

INFO Output parameter.

INFO is INTEGER

Error flag.

Related Information

For this routine in other precisions, please see *dlarrj*.

4.17.534 slarrk

slarrk computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from SSTEMR.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan “Accurate Eigenvalues of a Symmetric Tridiagonal Matrix”, Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarrk(N, IW, GL, GU, D, E2, PIVMIN, RELTOL, W, WERR, INFO)
```

C specification:

```
#include "armpl.h"

void slarrk_(const armpl_int_t *n, const armpl_int_t *iw, const float *gl,
             const float *gu, const float *d, const float *e2,
             const float *pivmin, const float *reltol, float *w, float *werr,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix T. N >= 0.

IW Input parameter.

IW is INTEGER

The index of the eigenvalues to be returned.

GL Input parameter.

GL is REAL

GU Input parameter.

GU is REAL

An upper and a lower bound on the eigenvalue.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the tridiagonal matrix T.

E2 Input parameter.

E2 is REAL

E2 is an array, dimension (N-1). The (n-1) squared off-diagonal elements of the tridiagonal matrix T.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot allowed in the Sturm sequence for T.

RELTOL Input parameter.

RELTOL is REAL

The minimum relative width of an interval. When an interval is narrower than RELTOL times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.

W Output parameter.

W is REAL

WERR Output parameter.

WERR is REAL

The error bound on the corresponding eigenvalue approximation in W.

INFO Output parameter.

INFO is INTEGER

= 0: Eigenvalue converged = -1: Eigenvalue did NOT converge

Related Information

For this routine in other precisions, please see *dlarrk*.

4.17.535 slarrr

Perform tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarrr(N, D, E, INFO)
```

C specification:

```
#include "armpl.h"

void slarrr_(const armpl_int_t *n, const float *d, float *e,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N > 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The N diagonal elements of the tridiagonal matrix T.

E Input and output parameter.

E is REAL

E is an array, dimension (N). On entry, the first (N-1) entries contain the subdiagonal elements of the tridiagonal matrix T; E(N) is set to ZERO.

INFO Output parameter.

INFO is INTEGER

INFO = 0(default) : the matrix warrants computations preserving relative accuracy. INFO = 1 : the matrix warrants computations guaranteeing only absolute accuracy.

Related Information

For this routine in other precisions, please see *dlarrr*.

4.17.536 slarrv

slarrv computes the eigenvectors of the tridiagonal matrix T = L D L^T given L, D and APPROXIMATIONS to the eigenvalues of L D L^T . The input eigenvalues should have been computed by SLARRE.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarrv(N, VL, VU, D, L, PIVMIN, ISPLIT, M, DOL, DOU, MINRGP, RTOL1,
                  RTOL2, W, WERR, WGAP, IBLOCK, INDEXW, GERS, Z, LDZ, ISUPPZ,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slarrv_(const armpl_int_t *n, const float *vl, const float *vu, float *d,
             float *l, float *pivmin, const armpl_int_t *isplit,
             const armpl_int_t *m, const armpl_int_t *dol,
             const armpl_int_t *dou, const float *minrgp, const float *rtol1,
             const float *rtol2, float *w, float *werr, float *wgap,
             const armpl_int_t *iblock, const armpl_int_t *indexw,
             const float *gers, float *z, const armpl_int_t *ldz,
             armpl_int_t *isuppz, float *work, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

VL Input parameter.

VL is REAL

Lower bound of the interval that contains the desired eigenvalues. VL < VU. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired RANGE.

VU Input parameter.

VU is REAL

Upper bound of the interval that contains the desired eigenvalues. VL < VU. Note: VU is currently not used by this implementation of SLARRV, VU is passed to SLARRV because it could be used compute gaps on the right end of the extremal eigenvalues. However, with not much initial accuracy in LAMBDA and VU, the formula can lead to an overestimation of the right gap and thus to inadequately early RQI 'convergence'. This is currently prevented this by forcing a small right gap. And so it turns out that VU is currently not used by this implementation of SLARRV.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the N diagonal elements of the diagonal matrix D. On exit, D may be overwritten.

L Input and output parameter.

L is REAL

L is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the unit bidiagonal matrix L are in elements 1 to N-1 of L (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by SLARRE. On exit, L is overwritten.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot allowed in the Sturm sequence.

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc.

M Input parameter.

M is INTEGER

The total number of input eigenvalues. 0 <= M <= N.

DOL Input parameter.

DOL is INTEGER

DOU Input parameter.

DOU is INTEGER

If the user wants to compute only selected eigenvectors from all the eigenvalues supplied, he can specify an index range DOL:DOU. Or else the setting DOL=1, DOU=M should be applied. Note that DOL and DOU refer to the order in which the eigenvalues are stored in W. If the user wants to compute only selected eigenpairs, then the columns DOL-1 to DOU+1 of the eigenvector space Z contain the computed eigenvectors. All other columns of Z are set to zero.

MINRGP Input parameter.

MINRGP is REAL

RTOL1 Input parameter.

RTOL1 is REAL

RTOL2 Input parameter.

RTOL2 is REAL

Parameters for bisection. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|))

W Input and output parameter.

W is REAL

W is an array, dimension (N). The first M elements of W contain the APPROXIMATE eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block (The output array W from SLARRE is expected here). Furthermore, they are with respect to the shift of the corresponding root representation for their block. On exit, W holds the eigenvalues of the UNshifted matrix.

WERR Input and output parameter.

WERR is REAL

WERR is an array, dimension (N). The first M elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in W

WGAP Input and output parameter.

WGAP is REAL

WGAP is an array, dimension (N). The separation from the right neighbor eigenvalue in W.

IBLOCK Input parameter.

IBLOCK is INTEGER array, dimension (N)

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first block from the top, =2 if W(i) belongs to the second block, etc.

INDEXW Input parameter.

INDEXW is INTEGER array, dimension (N)

The indices of the eigenvalues within each block (submatrix); for example, INDEXW(i)= 10 and IBLOCK(i)=2 imply that the i-th eigenvalue W(i) is the 10-th eigenvalue in the second block.

GERS Input parameter.

GERS is REAL

GERS is an array, dimension (2*N). The N Gerschgorin intervals (the i-th Gerschgorin interval is (GERS(2*i-1), GERS(2*i)). The Gerschgorin intervals should be computed from the original UNshifted matrix.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the input eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least max(1, M) columns are supplied in the array Z.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The I-th eigenvector is nonzero only in elements ISUPPZ(2*I-1) through ISUPPZ(2*I).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (12*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (7*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

> 0: A problem occurred in SLARRV. < 0: One of the called subroutines signaled an internal problem. Needs inspection of the corresponding parameter IINFO for further information.

=-1: Problem in SLARRB when refining a child's eigenvalues. =-2: Problem in SLARRF when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter MINRGP smaller and recompile. However, as the orthogonality of the computed vectors is proportional to 1/MINRGP, the user should be aware that he might be trading in precision when he decreases MINRGP. =-3: Problem in SLARRB when refining a single eigenvalue after the Rayleigh correction was rejected. = 5: The Rayleigh Quotient Iteration failed to converge to full accuracy in MAXITR steps.

Related Information

For this routine in other precisions, please see *clarrv*, *dlarrv* and *zlarrv*.

4.17.537 slarscl2

SLARSCL2 performs a reciprocal diagonal scaling on an vector:

```
x <-- inv(D) * x
```

where the diagonal matrix D is stored as a vector.

Eventually to be replaced by BLAS_sge_diag_scale in the new BLAS standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarscl2(M, N, D, X, LDX)
```

C specification:

```
#include "armpl.h"

void slarscl2_(const armpl_int_t *m, const armpl_int_t *n, const float *d,
               float *x, const armpl_int_t *ldx);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of D and X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of X. N >= 0.

D Input parameter.

D is REAL

D is an array, length M. Diagonal matrix D, stored as a vector of length M.

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, N). On entry, the vector X to be scaled by D. On exit, the scaled vector.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the vector X. LDX >= M.

Related Information

For this routine in other precisions, please see *clarscl2*, *dlarscl2* and *zlarscl2*.

4.17.538 slartg

`slartg` generate a plane rotation so that

```
[  CS  SN  ]  .  [ F ]  =  [ R ]   where CS**2 + SN**2 = 1.
[ -SN  CS  ]     [ G ]     [ 0 ]
```

This is a slower, more accurate version of the BLAS1 routine SROTG, with the following other differences:

```
F and G are unchanged on return.
If G=0, then CS=1 and SN=0.
If F=0 and (G .ne. 0), then CS=0 and SN=1 without doing any
   floating point operations (saves work in SBDSQR when
   there are zeros on the diagonal).
```

If F exceeds G in magnitude, CS will be positive.

Syntax

Fortran specification:

```
use armpl_library

subroutine slartg(F, G, CS, SN, R)
```

C specification:

```
#include "armpl.h"

void slartg_(const float *f, const float *g, float *cs, float *sn, float *r);
```

Parameters

F Input parameter.

F is REAL

The first component of vector to be rotated.

G Input parameter.

G is REAL

The second component of vector to be rotated.

CS Output parameter.

CS is REAL

The cosine of the rotation.

SN Output parameter.

SN is REAL

The sine of the rotation.

R Output parameter.

R is REAL

The nonzero component of the rotated vector.

This version has a few statements commented out for thread safety (machine parameters are computed on each entry). 10 feb 03, SJH.

Related Information

For this routine in other precisions, please see *clartg*, *dlartg* and *zlartg*.

4.17.539 slartgp

`slartgp` generates a plane rotation so that

```
[  CS  SN  ]  .  [ F ]  =  [ R ]   where CS**2 + SN**2 = 1.
[ -SN  CS  ]     [ G ]     [ 0 ]
```

This is a slower, more accurate version of the Level 1 BLAS routine SROTG, with the following other differences:

```
F and G are unchanged on return.
If G=0, then CS=(+/-)1 and SN=0.
If F=0 and (G .ne. 0), then CS=0 and SN=(+/-)1.
```

The sign is chosen so that R >= 0.

Syntax

Fortran specification:

```
use armpl_library

subroutine slartgp(F, G, CS, SN, R)
```

C specification:

```
#include "armpl.h"

void slartgp_(const float *f, const float *g, float *cs, float *sn,
              float *r);
```

Parameters

F Input parameter.

`F` is `REAL`

The first component of vector to be rotated.

G Input parameter.

`G` is `REAL`

The second component of vector to be rotated.

CS Output parameter.

`CS` is `REAL`

The cosine of the rotation.

SN Output parameter.

`SN` is `REAL`

The sine of the rotation.

R Output parameter.

R is REAL

The nonzero component of the rotated vector.

This version has a few statements commented out for thread safety (machine parameters are computed on each entry). 10 feb 03, SJH.

Related Information

For this routine in other precisions, please see *dlartgp*. It also exists with a native C interface as *LAPACKE_slartgp*.

4.17.540 slartgs

slartgs generates a plane rotation designed to introduce a bulge in Golub-Reinsch-style implicit QR iteration for the bidiagonal SVD problem. X and Y are the top-row entries, and SIGMA is the shift. The computed CS and SN define a plane rotation satisfying

```
[  CS  SN  ]  .  [ X^2 - SIGMA ]  =  [ R ],
[ -SN  CS  ]     [    X * Y    ]     [ 0 ]
```

with R nonnegative. If X^2 - SIGMA and X * Y are 0, then the rotation is by PI/2.

Syntax

Fortran specification:

```
use armpl_library

subroutine slartgs(X, Y, SIGMA, CS, SN)
```

C specification:

```
#include "armpl.h"

void slartgs_(const float *x, const float *y, const float *sigma, float *cs,
              float *sn);
```

Parameters

X Input parameter.

X is REAL

The (1,1) entry of an upper bidiagonal matrix.

Y Input parameter.

Y is REAL

The (1,2) entry of an upper bidiagonal matrix.

SIGMA Input parameter.

SIGMA is REAL

The shift.

CS Output parameter.

CS is REAL

The cosine of the rotation.

SN Output parameter.

SN is REAL

The sine of the rotation.

Related Information

For this routine in other precisions, please see *dlartgs*. It also exists with a native C interface as *LAPACKE_slartgs*.

4.17.541 slartv

slartv applies a vector of real plane rotations to elements of the real vectors x and y. For i = 1,2,...,n

```
( x(i) ) := (  c(i)  s(i) ) ( x(i) )
( y(i) )    ( -s(i)  c(i) ) ( y(i) )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slartv(N, X, INCX, Y, INCY, C, S, INCC)
```

C specification:

```
#include "armpl.h"

void slartv_(const armpl_int_t *n, float *x, const armpl_int_t *incx,
             float *y, const armpl_int_t *incy, const float *c,
             const float *s, const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be applied.

X Input and output parameter.

X is REAL

X is an array,. dimension (1+(N-1)*INCX) The vector x.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

Y Input and output parameter.

Y is REAL

Y is an array,. dimension (1+(N-1)*INCY) The vector y.

INCY Input parameter.

INCY is INTEGER

The increment between elements of Y. INCY > 0.

C Input parameter.

C is REAL

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

S Input parameter.

S is REAL

S is an array, dimension (1+(N-1)*INCC). The sines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C and S. INCC > 0.

Related Information

For this routine in other precisions, please see *clartv*, *dlartv* and *zlartv*.

4.17.542 slaruv

slaruv returns a vector of n random real numbers from a uniform (0,1) distribution (n <= 128).

This is an auxiliary routine called by SLARNV and CLARNV.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaruv(ISEED, N, X)
```

C specification:

```
#include "armpl.h"

void slaruv_(armpl_int_t *iseed, const armpl_int_t *n, float *x);
```

Parameters

ISEED Input and output parameter.

ISEED is INTEGER array, dimension (4)

On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and ISEED(4) must be odd. On exit, the seed is updated.

N Input parameter.

N is INTEGER

The number of random numbers to be generated. N <= 128.

X Output parameter.

X is REAL

X is an array, dimension (N). The generated random numbers.

Related Information

For this routine in other precisions, please see *dlaruv*.

4.17.543 slarz

slarz applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**T
```

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix.

H is a product of k elementary reflectors as returned by STZRZF.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarz(SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void slarz_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *l, const float *v, const armpl_int_t *incv,
            const float *tau, float *c, const armpl_int_t *ldc, float *work,
            ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

L Input parameter.

L is INTEGER

The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V Input parameter.

V is REAL

V is an array, dimension (1+(L-1)*abs(INCV)). The vector v in the representation of H as returned by STZRZF. V is not used if TAU = 0.

INCV Input parameter.

INCV is INTEGER

The increment between elements of v. INCV <> 0.

TAU Input parameter.

TAU is REAL

The value tau in the representation of H.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R'

Related Information

For this routine in other precisions, please see *clarz*, *dlarz* and *zlarz*.

4.17.544 slarzb

slarzb applies a real block reflector H or its transpose H^T to a real distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarzb(SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV, T, LDT, C,
                  LDC, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void slarzb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l, const float *v,
             const armpl_int_t *ldv, const float *t, const armpl_int_t *ldt,
             float *c, const armpl_int_t *ldc, float *work,
             const armpl_int_t *ldwork, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^T from the Left = 'R': apply H or H^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'C': apply H^T (Transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columnwise (not supported yet) = 'R': Rowwise

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

K Input parameter.

K is INTEGER

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L Input parameter.

L is INTEGER

The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V Input parameter.

V is REAL

V is an array, dimension (LDV,NV).. If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= L; if STOREV = 'R', LDV >= K.

T Input parameter.

T is REAL

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by H* C or H^T * C or C*H or C*H^T .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LDWORK, K) .

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1, N); if SIDE = 'R', LDWORK >= max(1, M).

Related Information

For this routine in other precisions, please see *clarzb*, *dlarzb* and *zlarzb*.

4.17.545 slarzt

slarzt forms the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

```
H  =  I - V * T * V**T
```

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

```
H  =  I - V**T * T * V
```

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

Syntax

Fortran specification:

```
use armpl_library

subroutine slarzt(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

C specification:

```
#include "armpl.h"

void slarzt_(const char *direct, const char *storev, const armpl_int_t *n,
             const armpl_int_t *k, float *v, const armpl_int_t *ldv,
             const float *tau, float *t, const armpl_int_t *ldt, ... );
```

Parameters

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details): = 'C': columnwise (not supported yet) = 'R': rowwise

N Input parameter.

N is INTEGER

The order of the block reflector H. N >= 0.

K Input parameter.

K is INTEGER

The order of the triangular factor T (= the number of elementary reflectors). K >= 1.

V Input and output parameter.

V is REAL

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, N) if STOREV = 'R' The matrix V. See further details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i).

T Output parameter.

T is REAL

T is an array, dimension (LDT, K). The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

Related Information

For this routine in other precisions, please see *clarzt*, *dlarzt* and *zlarzt*.

4.17.546 slas2

slas2 computes the singular values of the 2-by-2 matrix

```
[  F   G  ]
[  0   H  ].
```

On return, SSMIN is the smaller singular value and SSMAX is the larger singular value.

Syntax

Fortran specification:

```
use armpl_library

subroutine slas2(F, G, H, SSMIN, SSMAX)
```

C specification:

```
#include "armpl.h"

void slas2_(const float *f, const float *g, const float *h, float *ssmin,
            float *ssmax);
```

Parameters

F Input parameter.

F is REAL

The (1,1) element of the 2-by-2 matrix.

G Input parameter.

G is REAL

The (1,2) element of the 2-by-2 matrix.

H Input parameter.

H is REAL

The (2,2) element of the 2-by-2 matrix.

SSMIN Output parameter.

SSMIN is REAL

The smaller singular value.

SSMAX Output parameter.

SSMAX is REAL

The larger singular value.

Related Information

For this routine in other precisions, please see *dlas2*.

4.17.547 slascl

slascl multiplies the M by N real matrix A by the real scalar CTO/CFROM. This is done without over/underflow as long as the final result CTO*A(I,J)/CFROM does not over/underflow. TYPE specifies that A may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Syntax

Fortran specification:

```
use armpl_library

subroutine slascl(TYPE, KL, KU, CFROM, CTO, M, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void slascl_(const char *type, const armpl_int_t *kl, const armpl_int_t *ku,
             const float *cfrom, const float *cto, const armpl_int_t *m,
             const armpl_int_t *n, float *a, const armpl_int_t *lda,
             armpl_int_t *info, ... );
```

Parameters

TYPE Input parameter.

TYPE is CHARACTER*1

TYPE indices the storage type of the input matrix. = 'G': A is a full matrix. = 'L': A is a lower triangular matrix. = 'U': A is an upper triangular matrix. = 'H': A is an upper Hessenberg matrix. = 'B': A is a symmetric band matrix with lower bandwidth KL and upper bandwidth KU and with the only the lower half stored. = 'Q': A is a symmetric band matrix with lower bandwidth KL and upper bandwidth KU and with the only the upper half stored. = 'Z': A is a band matrix with lower bandwidth KL and upper bandwidth KU. See SGBTRF for storage details.

KL Input parameter.

KL is INTEGER

The lower bandwidth of A. Referenced only if TYPE = 'B', 'Q' or 'Z'.

KU Input parameter.

KU is INTEGER

The upper bandwidth of A. Referenced only if TYPE = 'B', 'Q' or 'Z'.

CFROM Input parameter.

CFROM is REAL

CTO Input parameter.

CTO is REAL

The matrix A is multiplied by CTO/CFROM. A(I,J) is computed without over/underflow if the final result CTO*A(I,J)/CFROM can be represented without over/underflow. CFROM must be nonzero.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). The matrix to be multiplied by CTO/CFROM. See TYPE for the storage type.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If TYPE = 'G', 'L', 'U', 'H', LDA >= max(1, M); TYPE = 'B', LDA >= KL+1; TYPE = 'Q', LDA >= KU+1; TYPE = 'Z', LDA >= 2*KL+KU+1.

INFO Output parameter.

INFO is INTEGER

0 - successful exit <0 - if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *clascl*, *dlascl* and *zlascl*. It also exists with a native C interface as *LAPACKE_slascl*.

4.17.548 slascl2

slascl2 performs a diagonal scaling on a vector:

```
x <-- D * x
```

where the diagonal matrix D is stored as a vector.

Eventually to be replaced by BLAS_sge_diag_scale in the new BLAS standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine slascl2(M, N, D, X, LDX)
```

C specification:

```
#include "armpl.h"

void slascl2_(const armpl_int_t *m, const armpl_int_t *n, const float *d,
              float *x, const armpl_int_t *ldx);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of D and X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of X. N >= 0.

D Input parameter.

D is REAL

D is an array, length M. Diagonal matrix D, stored as a vector of length M.

X Input and output parameter.

X is REAL

X is an array, dimension (LDX, N). On entry, the vector X to be scaled by D. On exit, the scaled vector.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the vector X. LDX >= M.

Related Information

For this routine in other precisions, please see *clascl2*, *dlascl2* and *zlascl2*.

4.17.549 slasd0

Using a divide and conquer approach, slasd0 computes the singular value decomposition (SVD) of a real upper bidiagonal N-by-M matrix B with diagonal D and offdiagonal E, where M = N + SQRE. The algorithm computes orthogonal matrices U and VT such that B = U * S * VT. The singular values S are overwritten on D.

A related subroutine, SLASDA, computes only the singular values, and optionally, the singular vectors in compact form.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasd0(N, SQRE, D, E, U, LDU, VT, LDVT, SMLSIZ, IWORK, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void slasd0_(const armpl_int_t *n, const armpl_int_t *sqre, float *d,
             float *e, float *u, const armpl_int_t *ldu, float *vt,
             const armpl_int_t *ldvt, const armpl_int_t *smlsiz,
             armpl_int_t *iwork, float *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

On entry, the row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array D.

SQRE Input parameter.

SQRE is INTEGER

Specifies the column dimension of the bidiagonal matrix. = 0: The bidiagonal matrix has column dimension M = N; = 1: The bidiagonal matrix has column dimension M = N+1;

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry D contains the main diagonal of the bidiagonal matrix. On exit D, if INFO = 0, contains its singular values.

E Input and output parameter.

E is REAL

E is an array, dimension (M-1). Contains the subdiagonal entries of the bidiagonal matrix. On exit, E has been destroyed.

U Output parameter.

U is REAL

U is an array, dimension (LDU, N). On exit, U contains the left singular vectors.

LDU Input parameter.

LDU is INTEGER

On entry, leading dimension of U.

VT Output parameter.

VT is REAL

VT is an array, dimension (LDVT, M). On exit, VT^T contains the right singular vectors.

LDVT Input parameter.

LDVT is INTEGER

On entry, leading dimension of VT.

SMLSIZ Input parameter.

SMLSIZ is INTEGER

On entry, maximum size of the subproblems at the bottom of the computation tree.

IWORK Output parameter.

IWORK is INTEGER array, dimension (8*N)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*M2+2*M)** .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *dlasd0*.

4.17.550 slasd1

slasd1 computes the SVD of an upper bidiagonal N-by-M matrix B, where N = NL + NR + 1 and M = N + SQRE. slasd1 is called from SLASD0.

A related subroutine SLASD7 handles the case in which the singular values (and the singular vectors in factored form) are desired.

slasd1 computes the SVD as follows:

```
             ( D1(in)     0     0        0 )
B = U(in) * (   Z1**T     a    Z2**T     b ) * VT(in)
             (   0        0    D2(in)    0 )

  = U(out) * ( D(out) 0) * VT(out)
```

where Z^T = ($Z1^T$ a $Z2^T$ b) = u^T VT^T , and u is a vector of dimension M with ALPHA and BETA in the NL+1 and NL+2 th entries and zeros elsewhere; and the entry b is empty if SQRE = 0.

The left singular vectors of the original matrix are stored in U, and the transpose of the right singular vectors are stored in VT, and the singular values are in D. The algorithm consists of three stages:

```
The first stage consists of deflating the size of the problem
when there are multiple singular values or when there are zeros in
the Z vector.  For each such occurrence the dimension of the
secular equation problem is reduced by one.  This stage is
performed by the routine SLASD2.

The second stage consists of calculating the updated
singular values. This is done by finding the square roots of the
roots of the secular equation via the routine SLASD4 (as called
by SLASD3). This routine also calculates the singular vectors of
the current problem.

The final stage consists of computing the updated singular vectors
directly using the updated singular values.  The singular vectors
for the current problem are multiplied with the singular vectors
from the overall problem.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slasd1(NL, NR, SQRE, D, ALPHA, BETA, U, LDU, VT, LDVT, IDXQ, IWORK,
                  WORK, INFO)
```

C specification:

```
#include "armpl.h"

void slasd1_(const armpl_int_t *nl, const armpl_int_t *nr,
             const armpl_int_t *sqre, float *d, float *alpha, float *beta,
             float *u, const armpl_int_t *ldu, float *vt,
             const armpl_int_t *ldvt, armpl_int_t *idxq, armpl_int_t *iwork,
             float *work, armpl_int_t *info);
```

Parameters

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has row dimension N = NL + NR + 1, and column dimension M = N + SQRE.

D Input and output parameter.

D is REAL

D is an array, dimension (NL+NR+1).. N = NL+NR+1 On entry D(1:NL,1:NL) contains the singular values of the upper block; and D(NL+2:N) contains the singular values of the lower block. On exit D(1:N) contains the singular values of the modified matrix.

ALPHA Input and output parameter.

ALPHA is REAL

Contains the diagonal element associated with the added row.

BETA Input and output parameter.

BETA is REAL

Contains the off-diagonal element associated with the added row.

U Input and output parameter.

U is REAL

U is an array, dimension (LDU,N). On entry U(1:NL, 1:NL) contains the left singular vectors of the upper block; U(NL+2:N, NL+2:N) contains the left singular vectors of the lower block. On exit U contains the left singular vectors of the bidiagonal matrix.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= max(1, N).

VT Input and output parameter.

VT is REAL

VT is an array, dimension (LDVT,M). where M = N + SQRE. On entry VT(1:NL+1, 1:NL+1)^T contains the right singular vectors of the upper block; VT(NL+2:M, NL+2:M)^T contains the right singular vectors of the lower block. On exit VT^T contains the right singular vectors of the bidiagonal matrix.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= max(1, M).

IDXQ Input and output parameter.

IDXQ is INTEGER array, dimension (N)

This contains the permutation which will reintegrate the subproblem just solved back into sorted order, i.e. D(IDXQ(I = 1, N)) will be in ascending order.

IWORK Output parameter.

IWORK is INTEGER array, dimension (4*N)

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*M2+2*M)** .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *dlasd1*.

4.17.551 slasd2

slasd2 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

slasd2 is called from SLASD1.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasd2(NL, NR, SQRE, K, D, Z, ALPHA, BETA, U, LDU, VT, LDVT,
                  DSIGMA, U2, LDU2, VT2, LDVT2, IDXP, IDX, IDXC, IDXQ, COLTYP,
                  INFO)
```

C specification:

```
#include "armpl.h"

void slasd2_(const armpl_int_t *nl, const armpl_int_t *nr,
             const armpl_int_t *sqre, armpl_int_t *k, float *d, float *z,
             const float *alpha, const float *beta, float *u,
             const armpl_int_t *ldu, float *vt, const armpl_int_t *ldvt,
             float *dsigma, float *u2, const armpl_int_t *ldu2, float *vt2,
             const armpl_int_t *ldvt2, armpl_int_t *idxp, armpl_int_t *idx,
             armpl_int_t *idxc, armpl_int_t *idxq, armpl_int_t *coltyp,
             armpl_int_t *info);
```

Parameters

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has N = NL + NR + 1 rows and M = N + SQRE >= N columns.

K Output parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. 1 <= K <=N.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry D contains the singular values of the two submatrices to be combined. On exit D contains the trailing (N-K) updated singular values (those which were deflated) sorted into increasing order.

Z Output parameter.

Z is REAL

Z is an array, dimension (N). On exit Z contains the updating row vector in the secular equation.

ALPHA Input parameter.

ALPHA is REAL

Contains the diagonal element associated with the added row.

BETA Input parameter.

BETA is REAL

Contains the off-diagonal element associated with the added row.

U Input and output parameter.

U is REAL

U is an array, dimension (LDU,N). On entry U contains the left singular vectors of two submatrices in the two square blocks with corners at (1,1), (NL, NL), and (NL+2, NL+2), (N,N). On exit U contains the trailing (N-K) updated left singular vectors (those which were deflated) in its last N-K columns.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= N.

VT Input and output parameter.

VT is REAL

VT is an array, dimension (LDVT,M). On entry VT^T contains the right singular vectors of two submatrices in the two square blocks with corners at (1,1), (NL+1, NL+1), and (NL+2, NL+2), (M,M). On exit VT^T contains the trailing (N-K) updated right singular vectors (those which were deflated) in its last N-K columns. In case SQRE =1, the last row of VT spans the right null space.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= M.

DSIGMA Output parameter.

DSIGMA is REAL

DSIGMA is an array, dimension (N). Contains a copy of the diagonal elements (K-1 singular values and one zero) in the secular equation.

U2 Output parameter.

U2 is REAL

U2 is an array, dimension (LDU2,N). Contains a copy of the first K-1 left singular vectors which will be used by SLASD3 in a matrix multiply (SGEMM) to solve for the new left singular vectors. U2 is arranged into four blocks. The first block contains a column with 1 at NL+1 and zero everywhere else; the second block contains non-zero entries only at and above NL; the third contains non-zero entries only below NL+1; and the fourth is dense.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of the array U2. LDU2 >= N.

VT2 Output parameter.

VT2 is REAL

VT2 is an array, dimension (LDVT2,N). $VT2^T$ contains a copy of the first K right singular vectors which will be used by SLASD3 in a matrix multiply (SGEMM) to solve for the new right singular vectors. VT2 is arranged into three blocks. The first block contains a row that corresponds to the special 0 diagonal element in SIGMA; the second block contains non-zeros only at and before NL +1; the third block contains non-zeros only at and after NL +2.

LDVT2 Input parameter.

LDVT2 is INTEGER

The leading dimension of the array VT2. LDVT2 >= M.

IDXP Output parameter.

IDXP is INTEGER array, dimension (N)

This will contain the permutation used to place deflated values of D at the end of the array. On output IDXP(2:K) points to the nondeflated D-values and IDXP(K+1:N) points to the deflated singular values.

IDX Output parameter.

IDX is INTEGER array, dimension (N)

This will contain the permutation used to sort the contents of D into ascending order.

IDXC Output parameter.

IDXC is INTEGER array, dimension (N)

This will contain the permutation used to arrange the columns of the deflated U matrix into three groups: the first group contains non-zero entries only at and above NL, the second contains non-zero entries only below NL+2, and the third is dense.

IDXQ Input and output parameter.

IDXQ is INTEGER array, dimension (N)

This contains the permutation which separately sorts the two sub-problems in D into ascending order. Note that entries in the first hlaf of this permutation must first be moved one position backward; and entries in the second half must first have NL+1 added to their values.

COLTYP Output parameter.

COLTYP is INTEGER array, dimension (N)

As workspace, this will contain a label which will indicate which of the following types a column in the U2 matrix or a row in the VT2 matrix is: 1 : non-zero in the upper half only 2 : non-zero in the lower half only 3 : dense 4 : deflated

On exit, it is an array of dimension 4, with COLTYP(I) being the dimension of the I-th type columns.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dlasd2*.

4.17.552 slasd3

slasd3 finds all the square roots of the roots of the secular equation, as defined by the values in D and Z. It makes the appropriate calls to SLASD4 and then updates the singular vectors by matrix multiplication.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

slasd3 is called from SLASD1.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasd3(NL, NR, SQRE, K, D, Q, LDQ, DSIGMA, U, LDU, U2, LDU2, VT,
                  LDVT, VT2, LDVT2, IDXC, CTOT, Z, INFO)
```

C specification:

```
#include "armpl.h"

void slasd3_(const armpl_int_t *nl, const armpl_int_t *nr,
             const armpl_int_t *sqre, const armpl_int_t *k, float *d,
             float *q, const armpl_int_t *ldq, float *dsigma, float *u,
             const armpl_int_t *ldu, const float *u2, const armpl_int_t *ldu2,
             float *vt, const armpl_int_t *ldvt, float *vt2,
             const armpl_int_t *ldvt2, const armpl_int_t *idxc,
             const armpl_int_t *ctot, float *z, armpl_int_t *info);
```

Parameters

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has N = NL + NR + 1 rows and M = N + SQRE >= N columns.

K Input parameter.

K is INTEGER

The size of the secular equation, 1 =< K = < N.

D Output parameter.

D is REAL

D is an array, dimension(K). On exit the square roots of the roots of the secular equation, in ascending order.

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ, K) .

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= K.

DSIGMA Input and output parameter.

DSIGMA is REAL

DSIGMA is an array, dimension(K). The first K elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

U Output parameter.

U is REAL

U is an array, dimension (LDU, N). The last N - K columns of this matrix contain the deflated left singular vectors.

LDU Input parameter.

LDU is INTEGER

The leading dimension of the array U. LDU >= N.

U2 Input parameter.

U2 is REAL

U2 is an array, dimension (LDU2, N). The first K columns of this matrix contain the non-deflated left singular vectors for the split problem.

LDU2 Input parameter.

LDU2 is INTEGER

The leading dimension of the array U2. LDU2 >= N.

VT Output parameter.

VT is REAL

VT is an array, dimension (LDVT, M). The last M - K columns of VT^T contain the deflated right singular vectors.

LDVT Input parameter.

LDVT is INTEGER

The leading dimension of the array VT. LDVT >= N.

VT2 Input and output parameter.

VT2 is REAL

VT2 is an array, dimension (LDVT2, N). The first K columns of $VT2^T$ contain the non-deflated right singular vectors for the split problem.

LDVT2 Input parameter.

LDVT2 is INTEGER

The leading dimension of the array VT2. LDVT2 >= N.

IDXC Input parameter.

IDXC is INTEGER array, dimension (N)

The permutation used to arrange the columns of U (and rows of VT) into three groups: the first group contains non-zero entries only at and above (or before) NL +1; the second contains non-zero entries only at and below (or after) NL+2; and the third is dense. The first column of U and the row of VT are treated separately, however.

The rows of the singular vectors found by SLASD4 must be likewise permuted before the matrix multiplies can take place.

CTOT Input parameter.

CTOT is INTEGER array, dimension (4)

A count of the total number of the various types of columns in U (or rows in VT), as described in IDXC. The fourth column type is any column which has been deflated.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (K). The first K elements of this array contain the components of the deflation-adjusted updating row vector.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *dlasd3*.

4.17.553 slasd4

This subroutine computes the square root of the I-th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix whose entries are given as the squares of the corresponding entries in the array d, and that

```
0 <= D(i) < D(j)  for  i < j
```

and that RHO > 0. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

```
diag( D ) * diag( D ) +  RHO * Z * Z_transpose.
```

where we assume the Euclidean norm of Z is 1.

The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasd4(N, I, D, Z, DELTA, RHO, SIGMA, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void slasd4_(const armpl_int_t *n, const armpl_int_t *i, const float *d,
             const float *z, float *delta, const float *rho, float *sigma,
             float *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The length of all arrays.

I Input parameter.

I is INTEGER

The index of the eigenvalue to be computed. 1 <= I <= N.

D Input parameter.

D is REAL

D is an array, dimension (N). The original eigenvalues. It is assumed that they are in order, 0 <= D(I) < D(J) for I < J.

Z Input parameter.

Z is REAL

Z is an array, dimension (N). The components of the updating vector.

DELTA Output parameter.

DELTA is REAL

DELTA is an array, dimension (N). If N .ne. 1, DELTA contains (D(j) - sigma_I) in its j-th component. If N = 1, then DELTA(1) = 1. The vector DELTA contains the information necessary to construct the (singular) eigenvectors.

RHO Input parameter.

RHO is REAL

The scalar in the symmetric updating formula.

SIGMA Output parameter.

SIGMA is REAL

The computed sigma_I, the I-th updated eigenvalue.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N). If N .ne. 1, WORK contains (D(j) + sigma_I) in its j-th component. If N = 1, then WORK(1) = 1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = 1, the updating process failed.

Related Information

For this routine in other precisions, please see *dlasd4*.

4.17.554 slasd5

This subroutine computes the square root of the I-th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix

```
diag( D ) * diag( D ) +  RHO * Z * transpose(Z) .
```

The diagonal entries in the array D are assumed to satisfy

```
0 <= D(i) < D(j)  for  i < j .
```

We also assume RHO > 0 and that the Euclidean norm of the vector Z is one.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasd5(I, D, Z, DELTA, RHO, DSIGMA, WORK)
```

C specification:

```
#include "armpl.h"

void slasd5_(const armpl_int_t *i, const float *d, const float *z,
             float *delta, const float *rho, float *dsigma, float *work);
```

Parameters

I Input parameter.

I is INTEGER

The index of the eigenvalue to be computed. I = 1 or I = 2.

D Input parameter.

D is REAL

D is an array, dimension (2). The original eigenvalues. We assume 0 <= D(1) < D(2).

Z Input parameter.

Z is REAL

Z is an array, dimension (2). The components of the updating vector.

DELTA Output parameter.

DELTA is REAL

DELTA is an array, dimension (2). Contains (D(j) - sigma_I) in its j-th component. The vector DELTA contains the information necessary to construct the eigenvectors.

RHO Input parameter.

RHO is REAL

The scalar in the symmetric updating formula.

DSIGMA Output parameter.

DSIGMA is REAL

The computed sigma_I, the I-th updated eigenvalue.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2). WORK contains (D(j) + sigma_I) in its j-th component.

Related Information

For this routine in other precisions, please see *dlasd5*.

4.17.555 slasd6

slasd6 computes the SVD of an updated upper bidiagonal matrix B obtained by merging two smaller ones by appending a row. This routine is used only for the problem which requires all singular values and optionally singular vector matrices in factored form. B is an N-by-M matrix with N = NL + NR + 1 and M = N + SQRE. A related subroutine, SLASD1, handles the case in which all singular values and singular vectors of the bidiagonal matrix are desired.

slasd6 computes the SVD as follows:

```
              ( D1(in)     0     0        0 )
B = U(in) * (    Z1**T     a    Z2**T     b ) * VT(in)
              (    0        0    D2(in)    0 )

  = U(out) * ( D(out) 0) * VT(out)
```

where Z^T = ($Z1^T$ a $Z2^T$ b) = u^T VT^T , and u is a vector of dimension M with ALPHA and BETA in the NL+1 and NL+2 th entries and zeros elsewhere; and the entry b is empty if SQRE = 0.

The singular values of B can be computed using D1, D2, the first components of all the right singular vectors of the lower block, and the last components of all the right singular vectors of the upper block. These components are stored and updated in VF and VL, respectively, in slasd6. Hence U and VT are not explicitly referenced.

The singular values are stored in D. The algorithm consists of two stages:

```
 The first stage consists of deflating the size of the problem
when there are multiple singular values or if there is a zero
in the Z vector. For each such occurrence the dimension of the
secular equation problem is reduced by one. This stage is
performed by the routine SLASD7.

The second stage consists of calculating the updated
singular values. This is done by finding the roots of the
secular equation via the routine SLASD4 (as called by SLASD8).
This routine also updates VF and VL and computes the distances
between the updated singular values and the old singular
values.
```

slasd6 is called from SLASDA.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasd6(ICOMPQ, NL, NR, SQRE, D, VF, VL, ALPHA, BETA, IDXQ, PERM,
                  GIVPTR, GIVCOL, LDGCOL, GIVNUM, LDGNUM, POLES, DIFL, DIFR,
                  Z, K, C, S, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slasd6_(const armpl_int_t *icompq, const armpl_int_t *nl,
             const armpl_int_t *nr, const armpl_int_t *sqre, float *d,
             float *vf, float *vl, float *alpha, float *beta,
             armpl_int_t *idxq, armpl_int_t *perm, armpl_int_t *givptr,
             armpl_int_t *givcol, const armpl_int_t *ldgcol, float *givnum,
             const armpl_int_t *ldgnum, float *poles, float *difl,
             float *difr, float *z, armpl_int_t *k, float *c, float *s,
             float *work, armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in factored form: = 0: Compute singular values only. = 1: Compute singular vectors in factored form as well.

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has row dimension N = NL + NR + 1, and column dimension M = N + SQRE.

D Input and output parameter.

D is REAL

D is an array, dimension (NL+NR+1).. On entry D(1:NL,1:NL) contains the singular values of the upper block, and D(NL+2:N) contains the singular values of the lower block. On exit D(1:N) contains the singular values of the modified matrix.

VF Input and output parameter.

VF is REAL

VF is an array, dimension (M). On entry, VF(1:NL+1) contains the first components of all right singular vectors of the upper block; and VF(NL+2:M) contains the first components of all right singular vectors of the lower block. On exit, VF contains the first components of all right singular vectors of the bidiagonal matrix.

VL Input and output parameter.

VL is REAL

VL is an array, dimension (M). On entry, VL(1:NL+1) contains the last components of all right singular vectors of the upper block; and VL(NL+2:M) contains the last components of all right singular vectors of the lower block. On exit, VL contains the last components of all right singular vectors of the bidiagonal matrix.

ALPHA Input and output parameter.

ALPHA is REAL

Contains the diagonal element associated with the added row.

BETA Input and output parameter.

BETA is REAL

Contains the off-diagonal element associated with the added row.

IDXQ Input and output parameter.

IDXQ is INTEGER array, dimension (N)

This contains the permutation which will reintegrate the subproblem just solved back into sorted order, i.e. D(IDXQ(I = 1, N)) will be in ascending order.

PERM Output parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) to be applied to each block. Not referenced if ICOMPQ = 0.

GIVPTR Output parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem. Not referenced if ICOMPQ = 0.

GIVCOL Output parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL Input parameter.

LDGCOL is INTEGER

leading dimension of GIVCOL, must be at least N.

GIVNUM Output parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (LDGNUM, 2). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM Input parameter.

LDGNUM is INTEGER

The leading dimension of GIVNUM and POLES, must be at least N.

POLES Output parameter.

POLES is REAL

POLES is an array, dimension (LDGNUM, 2). On exit, POLES(1,*) is an array containing the new singular values obtained from solving the secular equation, and POLES(2,*) is an array containing the poles in the secular equation. Not referenced if ICOMPQ = 0.

DIFL Output parameter.

DIFL is REAL

DIFL is an array, dimension (N). On exit, DIFL(I) is the distance between I-th updated (undeflated) singular value and the I-th (undeflated) old singular value.

DIFR Output parameter.

DIFR is REAL

DIFR is an array,. dimension (LDDIFR, 2) if ICOMPQ = 1 and dimension (K) if ICOMPQ = 0. On exit, DIFR(I,1) = D(I) - DSIGMA(I+1), DIFR(K,1) is not defined and will not be referenced.

If ICOMPQ = 1, DIFR(1:K,2) is an array containing the normalizing factors for the right singular vector matrix.

See SLASD8 for details on DIFL and DIFR.

Z Output parameter.

Z is REAL

Z is an array, dimension (M). The first elements of this array contain the components of the deflation-adjusted updating row vector.

K Output parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. 1 <= K <=N.

C Output parameter.

C is REAL

C contains garbage if SQRE =0 and the C-value of a Givens rotation related to the right null space if SQRE = 1.

S Output parameter.

S is REAL

S contains garbage if SQRE =0 and the S-value of a Givens rotation related to the right null space if SQRE = 1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4 * M) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (3 * N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *dlasd6*.

4.17.556 slasd7

slasd7 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

slasd7 is called from SLASD6.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasd7(ICOMPQ, NL, NR, SQRE, K, D, Z, ZW, VF, VFW, VL, VLW, ALPHA,
                  BETA, DSIGMA, IDX, IDXP, IDXQ, PERM, GIVPTR, GIVCOL, LDGCOL,
                  GIVNUM, LDGNUM, C, S, INFO)
```

C specification:

```
#include "armpl.h"

void slasd7_(const armpl_int_t *icompq, const armpl_int_t *nl,
             const armpl_int_t *nr, const armpl_int_t *sqre, armpl_int_t *k,
             float *d, float *z, float *zw, float *vf, float *vfw, float *vl,
             float *vlw, const float *alpha, const float *beta, float *dsigma,
             armpl_int_t *idx, armpl_int_t *idxp, const armpl_int_t *idxq,
             armpl_int_t *perm, armpl_int_t *givptr, armpl_int_t *givcol,
             const armpl_int_t *ldgcol, float *givnum,
             const armpl_int_t *ldgnum, float *c, float *s,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in compact form, as follows: = 0: Compute singular values only. = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has N = NL + NR + 1 rows and M = N + SQRE >= N columns.

K Output parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, this is the order of the related secular equation. 1 <= K <=N.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry D contains the singular values of the two submatrices to be combined. On exit D contains the trailing (N-K) updated singular values (those which were deflated) sorted into increasing order.

Z Output parameter.

Z is REAL

Z is an array, dimension (M). On exit Z contains the updating row vector in the secular equation.

ZW Output parameter.

ZW is REAL

ZW is an array, dimension (M). Workspace for Z.

VF Input and output parameter.

VF is REAL

VF is an array, dimension (M). On entry, VF(1:NL+1) contains the first components of all right singular vectors of the upper block; and VF(NL+2:M) contains the first components of all right singular vectors of the lower block. On exit, VF contains the first components of all right singular vectors of the bidiagonal matrix.

VFW Output parameter.

VFW is REAL

VFW is an array, dimension (M). Workspace for VF.

VL Input and output parameter.

VL is REAL

VL is an array, dimension (M). On entry, VL(1:NL+1) contains the last components of all right singular vectors of the upper block; and VL(NL+2:M) contains the last components of all right singular vectors of the lower block. On exit, VL contains the last components of all right singular vectors of the bidiagonal matrix.

VLW Output parameter.

VLW is REAL

VLW is an array, dimension (M). Workspace for VL.

ALPHA Input parameter.

ALPHA is REAL

Contains the diagonal element associated with the added row.

BETA Input parameter.

BETA is REAL

Contains the off-diagonal element associated with the added row.

DSIGMA Output parameter.

DSIGMA is REAL

DSIGMA is an array, dimension (N). Contains a copy of the diagonal elements (K-1 singular values and one zero) in the secular equation.

IDX Output parameter.

IDX is INTEGER array, dimension (N)

This will contain the permutation used to sort the contents of D into ascending order.

IDXP Output parameter.

IDXP is INTEGER array, dimension (N)

This will contain the permutation used to place deflated values of D at the end of the array. On output IDXP(2:K) points to the nondeflated D-values and IDXP(K+1:N) points to the deflated singular values.

IDXQ Input parameter.

IDXQ is INTEGER array, dimension (N)

This contains the permutation which separately sorts the two sub-problems in D into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have NL+1 added to their values.

PERM Output parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) to be applied to each singular block. Not referenced if ICOMPQ = 0.

GIVPTR Output parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem. Not referenced if ICOMPQ = 0.

GIVCOL Output parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL Input parameter.

LDGCOL is INTEGER

The leading dimension of GIVCOL, must be at least N.

GIVNUM Output parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (LDGNUM, 2). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM Input parameter.

LDGNUM is INTEGER

The leading dimension of GIVNUM, must be at least N.

C Output parameter.

C is REAL

C contains garbage if SQRE =0 and the C-value of a Givens rotation related to the right null space if SQRE = 1.

S Output parameter.

S is REAL

S contains garbage if SQRE =0 and the S-value of a Givens rotation related to the right null space if SQRE = 1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dlasd7*.

4.17.557 slasd8

slasd8 finds the square roots of the roots of the secular equation, as defined by the values in DSIGMA and Z. It makes the appropriate calls to SLASD4, and stores, for each element in D, the distance to its two nearest poles (elements in DSIGMA). It also updates the arrays VF and VL, the first and last components of all the right singular vectors of the original bidiagonal matrix.

slasd8 is called from SLASD6.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasd8(ICOMPQ, K, D, Z, VF, VL, DIFL, DIFR, LDDIFR, DSIGMA, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void slasd8_(const armpl_int_t *icompq, const armpl_int_t *k, float *d,
             float *z, float *vf, float *vl, float *difl, float *difr,
             const armpl_int_t *lddifr, float *dsigma, float *work,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in factored form in the calling routine: = 0: Compute singular values only. = 1: Compute singular vectors in factored form as well.

K Input parameter.

K is INTEGER

The number of terms in the rational function to be solved by SLASD4. K >= 1.

D Output parameter.

D is REAL

D is an array, dimension (K). On output, D contains the updated singular values.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (K). On entry, the first K elements of this array contain the components of the deflation-adjusted updating row vector. On exit, Z is updated.

VF Input and output parameter.

VF is REAL

VF is an array, dimension (K). On entry, VF contains information passed through DBEDE8. On exit, VF contains the first K components of the first components of all right singular vectors of the bidiagonal matrix.

VL Input and output parameter.

VL is REAL

VL is an array, dimension (K). On entry, VL contains information passed through DBEDE8. On exit, VL contains the first K components of the last components of all right singular vectors of the bidiagonal matrix.

DIFL Output parameter.

DIFL is REAL

DIFL is an array, dimension (K). On exit, DIFL(I) = D(I) - DSIGMA(I).

DIFR Output parameter.

DIFR is REAL

DIFR is an array,. dimension (LDDIFR, 2) if ICOMPQ = 1 and dimension (K) if ICOMPQ = 0. On exit, DIFR(I,1) = D(I) - DSIGMA(I+1), DIFR(K,1) is not defined and will not be referenced.

If ICOMPQ = 1, DIFR(1:K,2) is an array containing the normalizing factors for the right singular vector matrix.

LDDIFR Input parameter.

LDDIFR is INTEGER

The leading dimension of DIFR, must be at least K.

DSIGMA Input and output parameter.

DSIGMA is REAL

DSIGMA is an array, dimension (K). On entry, the first K elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation. On exit, the elements of DSIGMA may be very slightly altered in value.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*K) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *dlasd8*.

4.17.558 slasda

Using a divide and conquer approach, slasda computes the singular value decomposition (SVD) of a real upper bidiagonal N-by-M matrix B with diagonal D and offdiagonal E, where M = N + SQRE. The algorithm computes the singular values in the SVD B = U * S * VT. The orthogonal matrices U and VT are optionally computed in compact form.

A related subroutine, SLASD0, computes the singular values and the singular vectors in explicit form.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasda(ICOMPQ, SMLSIZ, N, SQRE, D, E, U, LDU, VT, K, DIFL, DIFR, Z,
                  POLES, GIVPTR, GIVCOL, LDGCOL, PERM, GIVNUM, C, S, WORK,
                  IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slasda_(const armpl_int_t *icompq, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *sqre, float *d,
             const float *e, float *u, const armpl_int_t *ldu, float *vt,
             armpl_int_t *k, float *difl, float *difr, float *z, float *poles,
             armpl_int_t *givptr, armpl_int_t *givcol,
             const armpl_int_t *ldgcol, armpl_int_t *perm, float *givnum,
             float *c, float *s, float *work, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in compact form, as follows = 0: Compute singular values only. = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

SMLSIZ Input parameter.

SMLSIZ is INTEGER

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

N is INTEGER

The row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array D.

SQRE Input parameter.

SQRE is INTEGER

Specifies the column dimension of the bidiagonal matrix. = 0: The bidiagonal matrix has column dimension M = N; = 1: The bidiagonal matrix has column dimension M = N + 1.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry D contains the main diagonal of the bidiagonal matrix. On exit D, if INFO = 0, contains its singular values.

E Input parameter.

E is REAL

E is an array, dimension (M-1). Contains the subdiagonal entries of the bidiagonal matrix. On exit, E has been destroyed.

U Output parameter.

U is REAL

U is an array,. dimension (LDU, SMLSIZ) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, U contains the left singular vector matrices of all subproblems at the bottom level.

LDU Input parameter.

LDU is INTEGER, LDU = > N.

The leading dimension of arrays U, VT, DIFL, DIFR, POLES, GIVNUM, and Z.

VT Output parameter.

VT is REAL

VT is an array,. dimension (LDU, SMLSIZ+1) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, VT^T contains the right singular vector matrices of all subproblems at the bottom level.

K Output parameter.

K is INTEGER array, dimension (N)

if ICOMPQ = 1 and dimension 1 if ICOMPQ = 0. If ICOMPQ = 1, on exit, K(I) is the dimension of the I-th secular equation on the computation tree.

DIFL Output parameter.

DIFL is REAL

DIFL is an array, dimension (LDU, NLVL),. where NLVL = floor(log_2 (N/SMLSIZ))).

DIFR Output parameter.

DIFR is REAL

DIFR is an array,. dimension (LDU, 2 * NLVL) if ICOMPQ = 1 and dimension (N) if ICOMPQ = 0. If ICOMPQ = 1, on exit, DIFL(1:N, I) and DIFR(1:N, 2 * I - 1) record distances between singular values on the I-th level and singular values on the (I -1)-th level, and DIFR(1:N, 2 * I) contains the normalizing factors for the right singular vector matrix. See SLASD8 for details.

Z Output parameter.

Z is REAL

Z is an array,. dimension (LDU, NLVL) if ICOMPQ = 1 and dimension (N) if ICOMPQ = 0. The first K elements of Z(1, I) contain the components of the deflation-adjusted updating row vector for subproblems on the I-th level.

POLES Output parameter.

POLES is REAL

POLES is an array,. dimension (LDU, 2 * NLVL) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, POLES(1, 2*I - 1) and POLES(1, 2*I) contain the new and old singular values involved in the secular equations on the I-th level.

GIVPTR Output parameter.

GIVPTR is INTEGER array,

dimension (N) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, GIVPTR(I) records the number of Givens rotations performed on the I-th problem on the computation tree.

GIVCOL Output parameter.

GIVCOL is INTEGER array,

dimension (LDGCOL, 2 * NLVL) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I, GIVCOL(1, 2 *I - 1) and GIVCOL(1, 2 *I) record the locations of Givens rotations performed on the I-th level on the computation tree.

LDGCOL Input parameter.

LDGCOL is INTEGER, LDGCOL = > N.

The leading dimension of arrays GIVCOL and PERM.

PERM Output parameter.

PERM is INTEGER array, dimension (LDGCOL, NLVL)

if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, PERM(1, I) records permutations done on the I-th level of the computation tree.

GIVNUM Output parameter.

GIVNUM is REAL

GIVNUM is an array,. dimension (LDU, 2 * NLVL) if ICOMPQ = 1, and not referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I, GIVNUM(1, 2 *I - 1) and GIVNUM(1, 2 *I) record the C- and S- values of Givens rotations performed on the I-th level on the computation tree.

C Output parameter.

C is REAL

C is an array,. dimension (N) if ICOMPQ = 1, and dimension 1 if ICOMPQ = 0. If ICOMPQ = 1 and the I-th subproblem is not square, on exit, C(I) contains the C-value of a Givens rotation related to the right null space of the I-th subproblem.

S Output parameter.

S is REAL

S is an array, dimension (N) if. ICOMPQ = 1, and dimension 1 if ICOMPQ = 0. If ICOMPQ = 1 and the I-th subproblem is not square, on exit, S(I) contains the S-value of a Givens rotation related to the right null space of the I-th subproblem.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension. (6 * N + (SMLSIZ + 1)*(SMLSIZ + 1)).

IWORK Output parameter.

IWORK is INTEGER array, dimension (7*N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, a singular value did not converge

Related Information

For this routine in other precisions, please see *dlasda*.

4.17.559 slasdq

slasdq computes the singular value decomposition (SVD) of a real (upper or lower) bidiagonal matrix with diagonal D and offdiagonal E, accumulating the transformations if desired. Letting B denote the input bidiagonal matrix, the algorithm computes orthogonal matrices Q and P such that B = Q * S * P^T (P^T denotes the transpose of P). The singular values S are overwritten on D.

The input matrix U is changed to U * Q if desired. The input matrix VT is changed to P^T * VT if desired. The input matrix C is changed to Q^T * C if desired.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3, for a detailed description of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasdq(UPLO, SQRE, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU, C,
                  LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void slasdq_(const char *uplo, const armpl_int_t *sqre, const armpl_int_t *n,
             const armpl_int_t *ncvt, const armpl_int_t *nru,
             const armpl_int_t *ncc, float *d, float *e, float *vt,
             const armpl_int_t *ldvt, float *u, const armpl_int_t *ldu,
             float *c, const armpl_int_t *ldc, float *work, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the input bidiagonal matrix is upper or lower bidiagonal, and whether it is square are not. UPLO = 'U' or 'u' B is upper bidiagonal. UPLO = 'L' or 'l' B is lower bidiagonal.

SQRE Input parameter.

SQRE is INTEGER

= 0: then the input matrix is N-by-N. = 1: then the input matrix is N-by-(N+1) if UPLU = 'U' and (N+1)-by-N if UPLU = 'L'.

The bidiagonal matrix has N = NL + NR + 1 rows and M = N + SQRE >= N columns.

N Input parameter.

N is INTEGER

On entry, N specifies the number of rows and columns in the matrix. N must be at least 0.

NCVT Input parameter.

NCVT is INTEGER

On entry, NCVT specifies the number of columns of the matrix VT. NCVT must be at least 0.

NRU Input parameter.

NRU is INTEGER

On entry, NRU specifies the number of rows of the matrix U. NRU must be at least 0.

NCC Input parameter.

NCC is INTEGER

On entry, NCC specifies the number of columns of the matrix C. NCC must be at least 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, D contains the diagonal entries of the bidiagonal matrix whose SVD is desired. On normal exit, D contains the singular values in ascending order.

E Input and output parameter.

E is REAL array.

dimension is (N-1) if SQRE = 0 and N if SQRE = 1. On entry, the entries of E contain the offdiagonal entries of the bidiagonal matrix whose SVD is desired. On normal exit, E will contain 0. If the algorithm does not converge, D and E will contain the diagonal and superdiagonal entries of a bidiagonal matrix orthogonally equivalent to the one given as input.

VT Input and output parameter.

VT is REAL

VT is an array, dimension (LDVT, NCVT). On entry, contains a matrix which on exit has been premultiplied by P^T , dimension N-by-NCVT if SQRE = 0 and (N+1)-by-NCVT if SQRE = 1 (not referenced if NCVT=0).

LDVT Input parameter.

LDVT is INTEGER

On entry, LDVT specifies the leading dimension of VT as declared in the calling (sub) program. LDVT must be at least 1. If NCVT is nonzero LDVT must also be at least N.

U Input and output parameter.

U is REAL

U is an array, dimension (LDU, N). On entry, contains a matrix which on exit has been postmultiplied by Q, dimension NRU-by-N if SQRE = 0 and NRU-by-(N+1) if SQRE = 1 (not referenced if NRU=0).

LDU Input parameter.

LDU is INTEGER

On entry, LDU specifies the leading dimension of U as declared in the calling (sub) program. LDU must be at least max(1, NRU) .

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, NCC). On entry, contains an N-by-NCC matrix which on exit has been premultiplied by Q^T dimension N-by-NCC if SQRE = 0 and (N+1)-by-NCC if SQRE = 1 (not referenced if NCC=0).

LDC Input parameter.

LDC is INTEGER

On entry, LDC specifies the leading dimension of C as declared in the calling (sub) program. LDC must be at least 1. If NCC is nonzero, LDC must also be at least N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N). Workspace. Only referenced if one of NCVT, NRU, or NCC is nonzero, and if N is at least 2.

INFO Output parameter.

INFO is INTEGER

On exit, a value of 0 indicates a successful exit. If INFO < 0, argument number -INFO is illegal. If INFO > 0, the algorithm did not converge, and INFO specifies how many superdiagonals did not converge.

Related Information

For this routine in other precisions, please see *dlasdq*.

4.17.560 slasdt

slasdt creates a tree of subproblems for bidiagonal divide and conquer.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasdt(N, LVL, ND, INODE, NDIML, NDIMR, MSUB)
```

C specification:

```
#include "armpl.h"

void slasdt_(const armpl_int_t *n, armpl_int_t *lvl, armpl_int_t *nd,
             armpl_int_t *inode, armpl_int_t *ndiml, armpl_int_t *ndimr,
             const armpl_int_t *msub);
```

Parameters

N Input parameter.

N is INTEGER

On entry, the number of diagonal elements of the bidiagonal matrix.

LVL Output parameter.

LVL is INTEGER

On exit, the number of levels on the computation tree.

ND Output parameter.

ND is INTEGER

On exit, the number of nodes on the tree.

INODE Output parameter.

INODE is INTEGER array, dimension (N)

On exit, centers of subproblems.

NDIML Output parameter.

NDIML is INTEGER array, dimension (N)

On exit, row dimensions of left children.

NDIMR Output parameter.

NDIMR is INTEGER array, dimension (N)

On exit, row dimensions of right children.

MSUB Input parameter.

MSUB is INTEGER

On entry, the maximum row dimension each subproblem at the bottom of the tree can be of.

Related Information

For this routine in other precisions, please see *dlasdt*.

4.17.561 slaset

slaset initializes an m-by-n matrix A to BETA on the diagonal and ALPHA on the offdiagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaset(UPLO, M, N, ALPHA, BETA, A, LDA)
```

C specification:

```
#include "armpl.h"

void slaset_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const float *alpha, const float *beta, float *a,
             const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be set. = 'U': Upper triangular part is set; the strictly lower triangular part of A is not changed. = 'L': Lower triangular part is set; the strictly upper triangular part of A is not changed. Otherwise: All of the matrix A is set.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

ALPHA Input parameter.

ALPHA is REAL

The constant to which the offdiagonal elements are to be set.

BETA Input parameter.

BETA is REAL

The constant to which the diagonal elements are to be set.

A Output parameter.

A is REAL

A is an array, dimension (LDA, N). On exit, the leading m-by-n submatrix of A is set as follows:

if UPLO = 'U', A(i,j) = ALPHA, 1<=i<=j-1, 1<=j<=n, if UPLO = 'L', A(i,j) = ALPHA, j+1<=i<=m, 1<=j<=n, otherwise, A(i,j) = ALPHA, 1<=i<=m, 1<=j<=n, i.ne.j,

and, for all UPLO, A(i,i) = BETA, 1<=i<=min(m,n).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

For this routine in other precisions, please see *claset*, *dlaset* and *zlaset*. It also exists with a native C interface as *LAPACKE_slaset*.

4.17.562 slasq1

`slasq1` computes the singular values of a real N-by-N bidiagonal matrix with diagonal D and off-diagonal E. The singular values are computed to high relative accuracy, in the absence of denormalization, underflow and overflow. The algorithm was first presented in

"Accurate singular values and differential qd algorithms" by K. V. Fernando and B. N. Parlett, Numer. Math., Vol-67, No. 2, pp. 191-230, 1994,

and the present implementation is described in "An implementation of the dqds Algorithm (Positive Case)", LAPACK Working Note.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasq1(N, D, E, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void slasq1_(const armpl_int_t *n, float *d, float *e, float *work,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows and columns in the matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, D contains the diagonal elements of the bidiagonal matrix whose SVD is desired. On normal exit, D contains the singular values in decreasing order.

E Input and output parameter.

E is REAL

E is an array, dimension (N). On entry, elements E(1:N-1) contain the off-diagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E is overwritten.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: the algorithm failed = 1, a split was marked by a positive value in E = 2, current block of Z not diagonalized after 100*N iterations (in inner while loop) On exit D and E represent a matrix with the same singular values which the calling subroutine could use to finish the computation, or even feed back into SLASQ1 = 3, termination criterion of outer while loop not met (program created more than N unreduced blocks)

Related Information

For this routine in other precisions, please see *dlasq1*.

4.17.563 slasq2

slasq2 computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the qd array Z to high relative accuracy are computed to high relative accuracy, in the absence of denormalization, underflow and overflow.

To see the relation of Z to the tridiagonal matrix, let L be a unit lower bidiagonal matrix with subdiagonals Z(2,4,6,,..) and let U be an upper bidiagonal matrix with 1's above and diagonal Z(1,3,5,,..). The tridiagonal is L*U or, if you prefer, the symmetric tridiagonal to which it is similar.

Note : slasq2 defines a logical variable, IEEE, which is true on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs, and false otherwise. This variable is passed to SLASQ3.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasq2(N, Z, INFO)
```

C specification:

```
#include "armpl.h"

void slasq2_(const armpl_int_t *n, float *z, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The number of rows and columns in the matrix. N >= 0.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (4* N). On entry Z holds the qd array. On exit, entries 1 to N hold the eigenvalues in decreasing order, Z(2*N+1) holds the trace, and Z(2*N+2) holds the sum of the eigenvalues. If N > 2, then Z(2*N+3) holds the iteration count, Z(2*N+4) holds NDIVS/NIN^2, and Z(2*N+5) holds the percentage of shifts that failed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if the i-th argument is a scalar and had an illegal value, then INFO = -i, if the i-th argument is an array and the j-entry had an illegal value, then INFO = -(i*100+j) > 0: the algorithm failed = 1, a split was marked by a positive value in E = 2, current block of Z not diagonalized after 100*N iterations (in inner while loop). On exit Z holds a qd array with the same eigenvalues as the given Z. = 3, termination criterion of outer while loop not met (program created more than N unreduced blocks)

Related Information

For this routine in other precisions, please see *dlasq2*.

4.17.564 slasq3

slasq3 checks for deflation, computes a shift (TAU) and calls dqds. In case of failure it changes shifts, and tries again until output is positive.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasq3(I0, N0, Z, PP, DMIN, SIGMA, DESIG, QMAX, NFAIL, ITER, NDIV,
                  IEEE, TTYPE, DMIN1, DMIN2, DN, DN1, DN2, G, TAU)
```

C specification:

```
#include "armpl.h"

void slasq3_(const armpl_int_t *i0, const armpl_int_t *n0, const float *z,
             armpl_int_t *pp, float *dmin, float *sigma, float *desig,
             const float *qmax, armpl_int_t *nfail, armpl_int_t *iter,
             armpl_int_t *ndiv, const armpl_int_t *ieee, armpl_int_t *ttype,
             float *dmin1, float *dmin2, float *dn, float *dn1, float *dn2,
             float *g, float *tau);
```

Parameters

I0 Input parameter.

I0 is INTEGER

First index.

N0 Input and output parameter.

N0 is INTEGER

Last index.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (4* N0). Z holds the qd array.

PP Input and output parameter.

PP is INTEGER

PP=0 for ping, PP=1 for pong. PP=2 indicates that flipping was applied to the Z array and that the initial tests for deflation should not be performed.

DMIN Output parameter.

DMIN is REAL

Minimum value of d.

SIGMA Output parameter.

SIGMA is REAL

Sum of shifts used in current segment.

DESIG Input and output parameter.

DESIG is REAL

Lower order part of SIGMA

QMAX Input parameter.

QMAX is REAL

Maximum value of q.

NFAIL Input and output parameter.

NFAIL is INTEGER

Increment NFAIL by 1 each time the shift was too big.

ITER Input and output parameter.

ITER is INTEGER

Increment ITER by 1 for each iteration.

NDIV Input and output parameter.

NDIV is INTEGER

Increment NDIV by 1 for each division.

IEEE Input parameter.

IEEE is LOGICAL

Flag for IEEE or non IEEE arithmetic (passed to SLASQ5).

TTYPE Input and output parameter.

TTYPE is INTEGER

Shift type.

DMIN1 Input and output parameter.

DMIN1 is REAL

DMIN2 Input and output parameter.

DMIN2 is REAL

DN Input and output parameter.

DN is REAL

DN1 Input and output parameter.

DN1 is REAL

DN2 Input and output parameter.

DN2 is REAL

G Input and output parameter.

G is REAL

TAU Input and output parameter.

TAU is REAL

These are passed as arguments in order to save their values between calls to SLASQ3.

Related Information

For this routine in other precisions, please see *dlasq3*.

4.17.565 slasq4

slasq4 computes an approximation TAU to the smallest eigenvalue using values of d from the previous transform.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasq4(I0, N0, Z, PP, N0IN, DMIN, DMIN1, DMIN2, DN, DN1, DN2, TAU,
                  TTYPE, G)
```

C specification:

```
#include "armpl.h"

void slasq4_(const armpl_int_t *i0, const armpl_int_t *n0, const float *z,
             const armpl_int_t *pp, armpl_int_t *n0in, const float *dmin,
             const float *dmin1, const float *dmin2, const float *dn,
             const float *dn1, const float *dn2, float *tau,
             armpl_int_t *ttype, float *g);
```

Parameters

I0 Input parameter.

I0 is INTEGER

First index.

N0 Input parameter.

N0 is INTEGER

Last index.

Z Input parameter.

Z is REAL

Z is an array, dimension (4* N0). Z holds the qd array.

PP Input parameter.

PP is INTEGER

PP=0 for ping, PP=1 for pong.

N0IN Input parameter.

N0IN is INTEGER

The value of N0 at start of EIGTEST.

DMIN Input parameter.

DMIN is REAL

Minimum value of d.

DMIN1 Input parameter.

DMIN1 is REAL

Minimum value of d, excluding D(N0).

DMIN2 Input parameter.

DMIN2 is REAL

Minimum value of d, excluding D(N0) and D(N0-1).

DN Input parameter.

DN is REAL

d(N)

DN1 Input parameter.

DN1 is REAL

d(N-1)

DN2 Input parameter.

DN2 is REAL

d(N-2)

TAU Output parameter.

TAU is REAL

This is the shift.

TTYPE Output parameter.

TTYPE is INTEGER

Shift type.

G Input and output parameter.

G is REAL

G is passed as an argument in order to save its value between calls to SLASQ4.

Related Information

For this routine in other precisions, please see *dlasq4*.

4.17.566 slasq5

slasq5 computes one dqds transform in ping-pong form, one version for IEEE machines another for non IEEE machines.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasq5(I0, N0, Z, PP, TAU, SIGMA, DMIN, DMIN1, DMIN2, DN, DNM1,
                  DNM2, IEEE, EPS)
```

C specification:

```
#include "armpl.h"

void slasq5_(const armpl_int_t *i0, const armpl_int_t *n0, const float *z,
             const armpl_int_t *pp, const float *tau, const float *sigma,
             float *dmin, float *dmin1, float *dmin2, float *dn, float *dnm1,
             float *dnm2, const armpl_int_t *ieee, const float *eps);
```

Parameters

I0 Input parameter.

I0 is INTEGER

First index.

N0 Input parameter.

N0 is INTEGER

Last index.

Z Input parameter.

Z is REAL

Z is an array, dimension (4*N). Z holds the qd array. EMIN is stored in Z(4*N0) to avoid an extra argument.

PP Input parameter.

PP is INTEGER

PP=0 for ping, PP=1 for pong.

TAU Input parameter.

TAU is REAL

This is the shift.

SIGMA Input parameter.

SIGMA is REAL

This is the accumulated shift up to this step.

DMIN Output parameter.

DMIN is REAL

Minimum value of d.

DMIN1 Output parameter.

DMIN1 is REAL

Minimum value of d, excluding D(N0).

DMIN2 Output parameter.

DMIN2 is REAL

Minimum value of d, excluding D(N0) and D(N0-1).

DN Output parameter.

DN is REAL

d(N0), the last value of d.

DNM1 Output parameter.

DNM1 is REAL

d(N0-1).

DNM2 Output parameter.

DNM2 is REAL

d(N0-2).

IEEE Input parameter.

IEEE is LOGICAL

Flag for IEEE or non IEEE arithmetic.

EPS Input parameter.

EPS is REAL

This is the value of epsilon used.

Related Information

For this routine in other precisions, please see *dlasq5*.

4.17.567 slasq6

slasq6 computes one dqd (shift equal to zero) transform in ping-pong form, with protection against underflow and overflow.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasq6(I0, N0, Z, PP, DMIN, DMIN1, DMIN2, DN, DNM1, DNM2)
```

C specification:

```
#include "armpl.h"

void slasq6_(const armpl_int_t *i0, const armpl_int_t *n0, const float *z,
             const armpl_int_t *pp, float *dmin, float *dmin1, float *dmin2,
             float *dn, float *dnm1, float *dnm2);
```

Parameters

I0 Input parameter.

I0 is INTEGER

First index.

N0 Input parameter.

N0 is INTEGER

Last index.

Z Input parameter.

Z is REAL

Z is an array, dimension (4*N). Z holds the qd array. EMIN is stored in Z(4*N0) to avoid an extra argument.

PP Input parameter.

PP is INTEGER

PP=0 for ping, PP=1 for pong.

DMIN Output parameter.

DMIN is REAL

Minimum value of d.

DMIN1 Output parameter.

DMIN1 is REAL

Minimum value of d, excluding D(N0).

DMIN2 Output parameter.

DMIN2 is REAL

Minimum value of d, excluding D(N0) and D(N0-1).

DN Output parameter.

DN is REAL

d(N0), the last value of d.

DNM1 Output parameter.

DNM1 is REAL

d(N0-1).

DNM2 Output parameter.

DNM2 is REAL

d(N0-2).

Related Information

For this routine in other precisions, please see *dlasq6*.

4.17.568 slasr

`slasr` applies a sequence of plane rotations to a real matrix A, from either the left or the right.

When SIDE = 'L', the transformation takes the form

```
A := P*A
```

and when SIDE = 'R', the transformation takes the form

```
A := A*P**T
```

where P is an orthogonal matrix consisting of a sequence of z plane rotations, with z = M when SIDE = 'L' and z = N when SIDE = 'R', and P^T is the transpose of P.

When DIRECT = 'F' (Forward sequence), then

```
P = P(z-1) * ... * P(2) * P(1)
```

and when DIRECT = 'B' (Backward sequence), then

```
P = P(1) * P(2) * ... * P(z-1)
```

where P(k) is a plane rotation matrix defined by the 2-by-2 rotation

```
R(k) = (  c(k)  s(k) )
     = ( -s(k)  c(k) ).
```

When PIVOT = 'V' (Variable pivot), the rotation is performed for the plane (k,k+1), i.e., P(k) has the form

```
P(k) = (  1                                          )
       (       ...                                   )
       (               1                             )
       (                    c(k)  s(k)               )
       (                   -s(k)  c(k)               )
       (                             1               )
       (                                  ...        )
       (                                         1   )
```

where R(k) appears as a rank-2 modification to the identity matrix in rows and columns k and k+1.

When PIVOT = 'T' (Top pivot), the rotation is performed for the plane (1,k+1), so P(k) has the form

```
P(k) = (  c(k)                    s(k)               )
       (         1                                   )
       (              ...                            )
       (                      1                      )
       ( -s(k)                c(k)                   )
       (                             1               )
       (                                  ...        )
       (                                         1   )
```

where R(k) appears in rows and columns 1 and k+1.

Similarly, when PIVOT = 'B' (Bottom pivot), the rotation is performed for the plane (k,z), giving P(k) the form

```
P(k) = ( 1                                           )
       (       ...                                   )
       (              1                              )
       (                   c(k)                s(k)  )
       (                          1                  )
       (                               ...           )
       (                                    1        )
       (                  -s(k)                c(k)  )
```

where R(k) appears in rows and columns k and z. The rotations are performed without ever forming P(k) explicitly.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasr(SIDE, PIVOT, DIRECT, M, N, C, S, A, LDA)
```

C specification:

```
#include "armpl.h"

void slasr_(const char *side, const char *pivot, const char *direct,
            const armpl_int_t *m, const armpl_int_t *n, const float *c,
            const float *s, float *a, const armpl_int_t *lda, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

Specifies whether the plane rotation matrix P is applied to A on the left or the right. = 'L': Left, compute A := P*A = 'R': Right, compute A:= A*P^T

PIVOT Input parameter.

PIVOT is CHARACTER*1

Specifies the plane for which P(k) is a plane rotation matrix. = 'V': Variable pivot, the plane (k,k+1) = 'T': Top pivot, the plane (1,k+1) = 'B': Bottom pivot, the plane (k,z)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies whether P is a forward or backward sequence of plane rotations. = 'F': Forward, P = P(z-1)*...*P(2)*P(1) = 'B': Backward, P = P(1)*P(2)*...*P(z-1)

M Input parameter.

M is INTEGER

The number of rows of the matrix A. If m <= 1, an immediate return is effected.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. If n <= 1, an immediate return is effected.

C Input parameter.

C is REAL

C is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' The cosines c(k) of the plane rotations.

S Input parameter.

S is REAL

S is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' The sines s(k) of the plane rotations. The 2-by-2 plane rotation part of the matrix P(k), R(k), has the form R(k) = (c(k) s(k)) (-s(k) c(k)).

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). The M-by-N matrix A. On exit, A is overwritten by P* A if SIDE = 'R' or by A*P^T if SIDE = 'L'.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

For this routine in other precisions, please see *clasr*, *dlasr* and *zlasr*.

4.17.569 slasrt

Sort the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of size <= 20. Dimension of STACK limits N to about 2**32.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasrt(ID, N, D, INFO)
```

C specification:

```
#include "armpl.h"

void slasrt_(const char *id, const armpl_int_t *n, float *d,
             armpl_int_t *info, ... );
```

Parameters

ID Input parameter.

ID is CHARACTER*1

= 'I': sort D in increasing order; = 'D': sort D in decreasing order.

N Input parameter.

N is INTEGER

The length of the array D.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the array to be sorted. On exit, D has been sorted into increasing order (D(1) <= ... <= D(N)) or into decreasing order (D(1) >= ... >= D(N)), depending on ID.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dlasrt*. It also exists with a native C interface as *LAPACKE_slasrt*.

4.17.570 slassq

slassq returns the values scl and smsq such that

```
( scl**2 )*smsq = x( 1 )**2 +...+ x( n )**2 + ( scale**2 )*sumsq,
```

where x(i) = X(1 + (i - 1)*INCX). The value of sumsq is assumed to be non-negative and scl returns the value

```
scl = max( scale, abs( x( i ) ) ).
```

scale and sumsq must be supplied in SCALE and SUMSQ and scl and smsq are overwritten on SCALE and SUMSQ respectively.

The routine makes only one pass through the vector x.

Syntax

Fortran specification:

```
use armpl_library

subroutine slassq(N, X, INCX, SCALE, SUMSQ)
```

C specification:

```
#include "armpl.h"

void slassq_(const armpl_int_t *n, const float *x, const armpl_int_t *incx,
             float *scale, float *sumsq);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements to be used from the vector X.

X Input parameter.

X is REAL

X is an array, dimension (N). The vector for which a scaled sum of squares is computed. x(i) = X(1 + (i - 1)* INCX), 1 <= i <= n.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of the vector X. INCX > 0.

SCALE Input and output parameter.

SCALE is REAL

On entry, the value scale in the equation above. On exit, SCALE is overwritten with scl , the scaling factor for the sum of squares.

SUMSQ Input and output parameter.

SUMSQ is REAL

On entry, the value sumsq in the equation above. On exit, SUMSQ is overwritten with smsq , the basic sum of squares from which scl has been factored out.

Related Information

For this routine in other precisions, please see *classq*, *dlassq* and *zlassq*. It also exists with a native C interface as *LAPACKE_slassq*.

4.17.571 slasv2

slasv2 computes the singular value decomposition of a 2-by-2 triangular matrix

```
[  F   G  ]
[  0   H  ].
```

On return, abs(SSMAX) is the larger singular value, abs(SSMIN) is the smaller singular value, and (CSL,SNL) and (CSR,SNR) are the left and right singular vectors for abs(SSMAX), giving the decomposition

```
[ CSL  SNL ] [  F   G  ] [ CSR -SNR ]  =  [ SSMAX   0   ]
[-SNL  CSL ] [  0   H  ] [ SNR  CSR ]     [  0    SSMIN ].
```

Syntax

Fortran specification:

```
use armpl_library

subroutine slasv2(F, G, H, SSMIN, SSMAX, SNR, CSR, SNL, CSL)
```

C specification:

```
#include "armpl.h"

void slasv2_(const float *f, const float *g, const float *h, float *ssmin,
             float *ssmax, float *snr, float *csr, float *snl, float *csl);
```

Parameters

F Input parameter.

F is REAL

The (1,1) element of the 2-by-2 matrix.

G Input parameter.

G is REAL

The (1,2) element of the 2-by-2 matrix.

H Input parameter.

H is REAL

The (2,2) element of the 2-by-2 matrix.

SSMIN Output parameter.

SSMIN is REAL

abs(SSMIN) is the smaller singular value.

SSMAX Output parameter.

SSMAX is REAL

abs(SSMAX) is the larger singular value.

SNL Output parameter.

SNL is REAL

CSL Output parameter.

CSL is REAL

The vector (CSL, SNL) is a unit left singular vector for the singular value abs(SSMAX).

SNR Output parameter.

SNR is REAL

CSR Output parameter.

CSR is REAL

The vector (CSR, SNR) is a unit right singular vector for the singular value abs(SSMAX).

Related Information

For this routine in other precisions, please see *dlasv2*.

4.17.572 slaswlq

slaswlq computes a blocked Short-Wide LQ factorization of a M-by-N matrix A, where N >= M: A = L * Q

Syntax

Fortran specification:

```
use armpl_library

subroutine slaswlq(M, N, MB, NB, A, LDA, T, LDT, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slaswlq_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *mb, const armpl_int_t *nb, float *a,
              const armpl_int_t *lda, float *t, const armpl_int_t *ldt,
              float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= M >= 0.

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. M >= MB >= 1

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. NB > M.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the N-by-N lower triangular matrix L; the elements above the diagonal represent Q by the rows of blocked V (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is REAL

T is an array,. dimension (LDT, N * Number_of_row_blocks) where Number_of_row_blocks = CEIL((N-M)/(NB-M)) The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details below.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

(workspace) REAL

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

The dimension of the array WORK. LWORK >= MB * M.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *claswlq*, *dlaswlq* and *zlaswlq*.

4.17.573 slaswp

slaswp performs a series of row interchanges on the matrix A. One row interchange is initiated for each of rows K1 through K2 of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine slaswp(N, A, LDA, K1, K2, IPIV, INCX)
```

C specification:

```
#include "armpl.h"

void slaswp_(const armpl_int_t *n, float *a, const armpl_int_t *lda,
             const armpl_int_t *k1, const armpl_int_t *k2,
             const armpl_int_t *ipiv, const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the matrix of column dimension N to which the row interchanges will be applied. On exit, the permuted matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A.

K1 Input parameter.

K1 is INTEGER

The first element of IPIV for which a row interchange will be done.

K2 Input parameter.

K2 is INTEGER

(K2-K1+1) is the number of elements of IPIV for which a row interchange will be done.

IPIV Input parameter.

IPIV is INTEGER array, dimension (K1+(K2-K1)*abs(INCX))

The vector of pivot indices. Only the elements in positions K1 through K1+(K2-K1)*abs(INCX) of IPIV are accessed. IPIV(K1+(K-K1)*abs(INCX)) = L implies rows K and L are to be interchanged.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of IPIV. If INCX is negative, the pivots are applied in reverse order.

Related Information

For this routine in other precisions, please see *claswp*, *dlaswp* and *zlaswp*. It also exists with a native C interface as *LAPACKE_slaswp*.

4.17.574 slasy2

`slasy2` solves for the N1 by N2 matrix X, 1 <= N1,N2 <= 2, in

```
op(TL)*X + ISGN*X*op(TR) = SCALE*B,
```

where TL is N1 by N1, TR is N2 by N2, B is N1 by N2, and ISGN = 1 or -1. op(T) = T or T^T , where T^T denotes the transpose of T.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasy2(LTRANL, LTRANR, ISGN, N1, N2, TL, LDTL, TR, LDTR, B, LDB,
                  SCALE, X, LDX, XNORM, INFO)
```

C specification:

```
#include "armpl.h"

void slasy2_(const armpl_int_t *ltranl, const armpl_int_t *ltranr,
             const armpl_int_t *isgn, const armpl_int_t *n1,
             const armpl_int_t *n2, const float *tl, const armpl_int_t *ldtl,
             const float *tr, const armpl_int_t *ldtr, const float *b,
             const armpl_int_t *ldb, float *scale, float *x,
             const armpl_int_t *ldx, float *xnorm, armpl_int_t *info);
```

Parameters

LTRANL Input parameter.

LTRANL is LOGICAL

On entry, LTRANL specifies the op(TL): = .FALSE., op(TL) = TL, = .TRUE., op(TL) = TL^T .

LTRANR Input parameter.

LTRANR is LOGICAL

On entry, LTRANR specifies the op(TR): = .FALSE., op(TR) = TR, = .TRUE., op(TR) = TR^T .

ISGN Input parameter.

ISGN is INTEGER

On entry, ISGN specifies the sign of the equation as described before. ISGN may only be 1 or -1.

N1 Input parameter.

N1 is INTEGER

On entry, N1 specifies the order of matrix TL. N1 may only be 0, 1 or 2.

N2 Input parameter.

N2 is INTEGER

On entry, N2 specifies the order of matrix TR. N2 may only be 0, 1 or 2.

TL Input parameter.

TL is REAL

TL is an array, dimension (LDTL,2). On entry, TL contains an N1 by N1 matrix.

LDTL Input parameter.

LDTL is INTEGER

The leading dimension of the matrix TL. LDTL >= max(1, N1).

TR Input parameter.

TR is REAL

TR is an array, dimension (LDTR,2). On entry, TR contains an N2 by N2 matrix.

LDTR Input parameter.

LDTR is INTEGER

The leading dimension of the matrix TR. LDTR >= max(1, N2).

B Input parameter.

B is REAL

B is an array, dimension (LDB,2). On entry, the N1 by N2 matrix B contains the right-hand side of the equation.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the matrix B. LDB >= max(1, N1).

SCALE Output parameter.

SCALE is REAL

On exit, SCALE contains the scale factor. SCALE is chosen less than or equal to 1 to prevent the solution overflowing.

X Output parameter.

X is REAL

X is an array, dimension (LDX,2). On exit, X contains the N1 by N2 solution.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the matrix X. LDX >= max(1, N1).

XNORM Output parameter.

XNORM is REAL

On exit, XNORM is the infinity-norm of the solution.

INFO Output parameter.

INFO is INTEGER

On exit, INFO is set to 0: successful exit. 1: TL and TR have too close eigenvalues, so TL or TR is perturbed to get a nonsingular equation. NOTE: In the interests of speed, this routine does not check the inputs for errors.

Related Information

For this routine in other precisions, please see *dlasy2*.

4.17.575 slasyf

`slasyf` computes a partial factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

`slasyf` is an auxiliary routine called by SSYTRF. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine slasyf(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void slasyf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             armpl_int_t *kb, float *a, const armpl_int_t *lda,
             armpl_int_t *ipiv, float *w, const armpl_int_t *ldw,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is REAL

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *clasyf*, *dlasyf* and *zlasyf*.

4.17.576 slasyf_aa

DLATRF_AA factorizes a panel of a real symmetric matrix A using the Aasen's algorithm. The panel consists of a set of NB rows of A when UPLO is U, or a set of NB columns when UPLO is L.

In order to factorize the panel, the Aasen's algorithm requires the last row, or column, of the previous panel. The first row, or column, of A is set to be the first row, or column, of an identity matrix, which is used to factorize the first panel.

The resulting J-th row of U, or J-th column of L, is stored in the (J-1)-th row, or column, of A (without the unit diagonals), while the diagonal and subdiagonal of A are overwritten by those of T.

Syntax

Fortran specification:

```
use armpl_library

subroutine slasyf_aa(UPLO, J1, M, NB, A, LDA, IPIV, H, LDH, WORK)
```

C specification:

```
#include "armpl.h"

void slasyf_aa_(const char *uplo, const armpl_int_t *j1, const armpl_int_t *m,
                const armpl_int_t *nb, float *a, const armpl_int_t *lda,
                armpl_int_t *ipiv, float *h, const armpl_int_t *ldh,
                float *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

J1 Input parameter.

J1 is INTEGER

The location of the first row, or column, of the panel within the submatrix of A, passed to this routine, e.g., when called by SSYTRF_AA, for the first panel, J1 is 1, while for the remaining panels, J1 is 2.

M Input parameter.

M is INTEGER

The dimension of the submatrix. M >= 0.

NB Input parameter.

NB is INTEGER

The dimension of the panel to be facotorized.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, M) for. the first panel, while dimension (LDA,M+1) for the remaining panels.

On entry, A contains the last row, or column, of the previous panel, and the trailing submatrix of A to be factorized, except for the first panel, only the panel is passed.

On exit, the leading panel is factorized.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (M)

Details of the row and column interchanges, the row and column k were interchanged with the row and column IPIV(k).

H Input and output parameter.

H is REAL workspace, dimension (LDH, NB).

LDH Input parameter.

LDH is INTEGER

The leading dimension of the workspace H. LDH >= max(1, M).

WORK Output parameter.

WORK is REAL workspace, dimension (M).

4.17.577 slasyf_rook

SLASYF_ROOK computes a partial factorization of a real symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

SLASYF_ROOK is an auxiliary routine called by SSYTRF_ROOK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine slasyf_rook(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void slasyf_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nb, armpl_int_t *kb, float *a,
                  const armpl_int_t *lda, armpl_int_t *ipiv, float *w,
                  const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is REAL

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *clasyf_rook*, *dlasyf_rook* and *zlasyf_rook*.

4.17.578 slatbs

slatbs solves one of the triangular systems

```
A *x = s*b  or  A**T*x = s*b
```

with scaling to prevent overflow, where A is an upper or lower triangular band matrix. Here A^T denotes the transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine STBSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine slatbs(UPLO, TRANS, DIAG, NORMIN, N, KD, AB, LDAB, X, SCALE, CNORM,
                  INFO)
```

C specification:

```
#include "armpl.h"

void slatbs_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n, const armpl_int_t *kd,
             const float *ab, const armpl_int_t *ldab, float *x, float *scale,
             float *cnorm, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^T * x = s*b (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of subdiagonals or superdiagonals in the triangular matrix A. KD >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

X Input and output parameter.

X is REAL

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is REAL

The scaling factor s for the triangular system A * x = s*b or A^T * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is REAL

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatbs*, *dlatbs* and *zlatbs*.

4.17.579 slatdf

slatdf uses the LU factorization of the n-by-n matrix Z computed by SGETC2 and computes a contribution to the reciprocal Dif-estimate by solving Z * x = b for x, and choosing the r.h.s. b such that the norm of x is as large as possible. On entry RHS = b holds the contribution from earlier solved sub-systems, and on return RHS = x.

The factorization of Z returned by SGETC2 has the form Z = P*L*U*Q, where P and Q are permutation matrices. L is lower triangular with unit diagonal elements and U is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine slatdf(IJOB, N, Z, LDZ, RHS, RDSUM, RDSCAL, IPIV, JPIV)
```

C specification:

```
#include "armpl.h"

void slatdf_(const armpl_int_t *ijob, const armpl_int_t *n, const float *z,
             const armpl_int_t *ldz, float *rhs, float *rdsum, float *rdscal,
             const armpl_int_t *ipiv, const armpl_int_t *jpiv);
```

Parameters

IJOB Input parameter.

IJOB is INTEGER

IJOB = 2: First compute an approximative null-vector e of Z using SGECON, e is normalized and solve for Zx = +-e - f with the sign giving the greater value of 2-norm(x). About 5 times as expensive as Default. IJOB .ne. 2: Local look ahead strategy where all entries of the r.h.s. b is chosen as either +1 or -1 (Default).

N Input parameter.

N is INTEGER

The number of columns of the matrix Z.

Z Input parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, the LU part of the factorization of the n-by-n matrix Z computed by SGETC2: Z = P * L * U * Q

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDA >= max(1, N).

RHS Input and output parameter.

RHS is REAL

RHS is an array, dimension N.. On entry, RHS contains contributions from other subsystems. On exit, RHS contains the solution of the subsystem with entries acoording to the value of IJOB (see above).

RDSUM Input and output parameter.

RDSUM is REAL

On entry, the sum of squares of computed contributions to the Dif-estimate under computation by STGSYL, where the scaling factor RDSCAL (see below) has been factored out. On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If TRANS = 'T' RDSUM is not touched. NOTE: RDSUM only makes sense when STGSY2 is called by STGSYL.

RDSCAL Input and output parameter.

RDSCAL is REAL

On entry, scaling factor used to prevent overflow in RDSUM. On exit, RDSCAL is updated w.r.t. the current contributions in RDSUM. If TRANS = 'T', RDSCAL is not touched. NOTE: RDSCAL only makes sense when STGSY2 is called by STGSYL.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Input parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

Related Information

For this routine in other precisions, please see *clatdf*, *dlatdf* and *zlatdf*.

4.17.580 slatps

slatps solves one of the triangular systems

```
A *x = s*b  or  A**T*x = s*b
```

with scaling to prevent overflow, where A is an upper or lower triangular matrix stored in packed form. Here A^T denotes the transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine STPSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine slatps(UPLO, TRANS, DIAG, NORMIN, N, AP, X, SCALE, CNORM, INFO)
```

C specification:

```
#include "armpl.h"

void slatps_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n, const float *ap,
             float *x, float *scale, float *cnorm, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^T * x = s*b (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

X Input and output parameter.

X is REAL

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is REAL

The scaling factor s for the triangular system A * x = s*b or A^T * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is REAL

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatps*, *dlatps* and *zlatps*.

4.17.581 slatrd

slatrd reduces NB rows and columns of a real symmetric matrix A to symmetric tridiagonal form by an orthogonal similarity transformation Q^T * A * Q, and returns the matrices V and W which are needed to apply the transformation to the unreduced part of A.

If UPLO = 'U', slatrd reduces the last NB rows and columns of a matrix, of which the upper triangle is supplied; if UPLO = 'L', slatrd reduces the first NB rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by SSYTRD.

Syntax

Fortran specification:

```
use armpl_library

subroutine slatrd(UPLO, N, NB, A, LDA, E, TAU, W, LDW)
```

C specification:

```
#include "armpl.h"

void slatrd_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             float *a, const armpl_int_t *lda, float *e, float *tau, float *w,
             const armpl_int_t *ldw, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A.

NB Input parameter.

NB is INTEGER

The number of rows and columns to be reduced.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit: if UPLO = 'U', the last NB columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of A; the elements above the diagonal with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the first NB columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of A; the elements below the diagonal with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= (1, N).

E Output parameter.

E is REAL

E is an array, dimension (N-1). If UPLO = 'U', E(n-nb:n-1) contains the superdiagonal elements of the last NB columns of the reduced matrix; if UPLO = 'L', E(1:nb) contains the subdiagonal elements of the first NB columns of the reduced matrix.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors, stored in TAU(n-nb:n-1) if UPLO = 'U', and in TAU(1:nb) if UPLO = 'L'. See Further Details.

W Output parameter.

W is REAL

W is an array, dimension (LDW, NB). The n-by-nb matrix W required to update the unreduced part of A.

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

Related Information

For this routine in other precisions, please see *clatrd*, *dlatrd* and *zlatrd*.

4.17.582 slatrs

slatrs solves one of the triangular systems

```
A *x = s*b  or  A**T*x = s*b
```

with scaling to prevent overflow. Here A is an upper or lower triangular matrix, A^T denotes the transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine STRSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine slatrs(UPLO, TRANS, DIAG, NORMIN, N, A, LDA, X, SCALE, CNORM,
                  INFO)
```

C specification:

```
#include "armpl.h"

void slatrs_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n, const float *a,
             const armpl_int_t *lda, float *x, float *scale, float *cnorm,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^T * x = s*b (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max (1, N).

X Input and output parameter.

X is REAL

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is REAL

The scaling factor s for the triangular system A * x = s*b or A^T * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is REAL

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatrs*, *dlatrs* and *zlatrs*.

4.17.583 slatrz

slatrz factors the M-by-(M+L) real upper trapezoidal matrix [A1 A2] = [A(1:M,1:M) A(1:M,N-L+1:N)] as (R 0) * Z, by means of orthogonal transformations. Z is an (M+L)-by-(M+L) orthogonal matrix and, R and A1 are M-by-M upper triangular matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine slatrz(M, N, L, A, LDA, TAU, WORK)
```

C specification:

```
#include "armpl.h"

void slatrz_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             float *a, const armpl_int_t *lda, float *tau, float *work);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder vectors. N-M >= L >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements N-L+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (M). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (M) .

Related Information

For this routine in other precisions, please see *clatrz*, *dlatrz* and *zlatrz*.

4.17.584 slatsqr

slatsqr computes a blocked Tall-Skinny QR factorization of an M-by-N matrix A, where M >= N: A = Q * R .

Syntax

Fortran specification:

```
use armpl_library

subroutine slatsqr(M, N, MB, NB, A, LDA, T, LDT, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void slatsqr_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *mb, const armpl_int_t *nb, float *a,
              const armpl_int_t *lda, float *t, const armpl_int_t *ldt,
              float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. M >= N >= 0.

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. MB > N.

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. N >= NB >= 1.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the N-by-N upper triangular matrix R; the elements below the diagonal represent Q by the columns of blocked V (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is REAL

T is an array,. dimension (LDT, N * Number_of_row_blocks) where Number_of_row_blocks = CEIL((M-N)/(MB-N)) The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details below.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

(workspace) REAL

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

The dimension of the array WORK. LWORK >= NB*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatsqr*, *dlatsqr* and *zlatsqr*.

4.17.585 slauu2

`slauu2` computes the product U * U^T or L^T * L, where the triangular factor U or L is stored in the upper or lower triangular part of the array A.

If UPLO = 'U' or 'u' then the upper triangle of the result is stored, overwriting the factor U in A. If UPLO = 'L' or 'l' then the lower triangle of the result is stored, overwriting the factor L in A.

This is the unblocked form of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine slauu2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void slauu2_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the triangular factor stored in the array A is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the triangular factor U or L. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the triangular factor U or L. On exit, if UPLO = 'U', the upper triangle of A is overwritten with the upper triangle of the product U * U^T ; if UPLO = 'L', the lower triangle of A is overwritten with the lower triangle of the product L^T * L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clauu2*, *dlauu2* and *zlauu2*.

4.17.586 slauum

`slauum` computes the product U * U^T or L^T * L, where the triangular factor U or L is stored in the upper or lower triangular part of the array A.

If UPLO = 'U' or 'u' then the upper triangle of the result is stored, overwriting the factor U in A. If UPLO = 'L' or 'l' then the lower triangle of the result is stored, overwriting the factor L in A.

This is the blocked form of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine slauum(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void slauum_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the triangular factor stored in the array A is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the triangular factor U or L. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the triangular factor U or L. On exit, if UPLO = 'U', the upper triangle of A is overwritten with the upper triangle of the product U * U^T ; if UPLO = 'L', the lower triangle of A is overwritten with the lower triangle of the product L^T * L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clauum*, *dlauum* and *zlauum*. It also exists with a native C interface as *LAPACKE_slauum*.

4.17.587 sorbdb1

`sorbdb1` simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                         [ B11 ]
[ X11 ]    [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]    [    | P2 ] [ B21 ]
                         [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. Q must be no larger than P, M-P, or M-Q. Routines SORBDB2, SORBDB3, and SORBDB4 handle cases in which Q is not the minimum dimension.

The orthogonal matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are Q-by-Q bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorbdb1(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorbdb1_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, float *x11, const armpl_int_t *ldx11,
              float *x21, const armpl_int_t *ldx21, float *theta, float *phi,
              float *taup1, float *taup2, float *tauq1, float *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= MIN(P,M-P,M-Q).

X11 Input and output parameter.

X11 is REAL

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is REAL

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is REAL

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is REAL

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is REAL

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dorbdb1*.

4.17.588 sorbdb2

sorbdb2 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                         [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                         [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. P must be no larger than M-P, Q, or M-Q. Routines SORBDB1, SORBDB3, and SORBDB4 handle cases in which P is not the minimum dimension.

The orthogonal matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are P-by-P bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorbdb2(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorbdb2_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, float *x11, const armpl_int_t *ldx11,
              float *x21, const armpl_int_t *ldx21, float *theta, float *phi,
              float *taup1, float *taup2, float *tauq1, float *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= min(M-P, Q,M-Q).

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is REAL

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is REAL

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is REAL

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is REAL

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is REAL

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dorbdb2*.

4.17.589 sorbdb3

sorbdb3 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                         [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                         [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. M-P must be no larger than P, Q, or M-Q. Routines SORBDB1, SORBDB2, and SORBDB4 handle cases in which M-P is not the minimum dimension.

The orthogonal matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are (M-P)-by-(M-P) bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorbdb3(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorbdb3_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, float *x11, const armpl_int_t *ldx11,
              float *x21, const armpl_int_t *ldx21, float *theta, float *phi,
              float *taup1, float *taup2, float *tauq1, float *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M. M-P <= min(P, Q,M-Q).

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is REAL

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is REAL

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is REAL

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is REAL

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is REAL

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dorbdb3*.

4.17.590 sorbdb4

sorbdb4 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                         [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                         [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. M-Q must be no larger than P, M-P, or Q. Routines SORBDB1, SORBDB2, and SORBDB3 handle cases in which M-Q is not the minimum dimension.

The orthogonal matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are (M-Q)-by-(M-Q) bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorbdb4(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, PHANTOM, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorbdb4_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, float *x11, const armpl_int_t *ldx11,
              float *x21, const armpl_int_t *ldx21, float *theta, float *phi,
              float *taup1, float *taup2, float *tauq1, float *phantom,
              float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M and M-Q <= min(P,M-P, Q).

X11 Input and output parameter.

X11 is REAL

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is REAL

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is REAL

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is REAL

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is REAL

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is REAL

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is REAL

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

PHANTOM Output parameter.

PHANTOM is REAL

PHANTOM is an array, dimension (M). The routine computes an M-by-1 column vector Y that is orthogonal to the columns of [X11; X21]. PHANTOM(1:P) and PHANTOM(P+1:M) contain Householder vectors for Y(1:P) and Y(P+1:M), respectively.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dorbdb4*.

4.17.591 sorbdb5

sorbdb5 orthogonalizes the column vector

```
X = [ X1 ]
    [ X2 ]
```

with respect to the columns of

```
Q = [ Q1 ] .
    [ Q2 ]
```

The columns of Q must be orthonormal.

If the projection is zero according to Kahan's "twice is enough" criterion, then some other vector from the orthogonal complement is returned. This vector is chosen in an arbitrary but deterministic way.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorbdb5(M1, M2, N, X1, INCX1, X2, INCX2, Q1, LDQ1, Q2, LDQ2, WORK,
                   LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorbdb5_(const armpl_int_t *m1, const armpl_int_t *m2,
              const armpl_int_t *n, float *x1, const armpl_int_t *incx1,
              float *x2, const armpl_int_t *incx2, float *q1,
              const armpl_int_t *ldq1, float *q2, const armpl_int_t *ldq2,
              float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M1 Input parameter.

M1 is INTEGER

The dimension of X1 and the number of rows in Q1. 0 <= M1.

M2 Input parameter.

M2 is INTEGER

The dimension of X2 and the number of rows in Q2. 0 <= M2.

N Input parameter.

N is INTEGER

The number of columns in Q1 and Q2. 0 <= N.

X1 Input and output parameter.

X1 is REAL

X1 is an array, dimension (M1). On entry, the top part of the vector to be orthogonalized. On exit, the top part of the projected vector.

INCX1 Input parameter.

INCX1 is INTEGER

Increment for entries of X1.

X2 Input and output parameter.

X2 is REAL

X2 is an array, dimension (M2). On entry, the bottom part of the vector to be orthogonalized. On exit, the bottom part of the projected vector.

INCX2 Input parameter.

INCX2 is INTEGER

Increment for entries of X2.

Q1 Input parameter.

Q1 is REAL

Q1 is an array, dimension (LDQ1, N). The top part of the orthonormal basis matrix.

LDQ1 Input parameter.

LDQ1 is INTEGER

The leading dimension of Q1. LDQ1 >= M1.

Q2 Input parameter.

Q2 is REAL

Q2 is an array, dimension (LDQ2, N). The bottom part of the orthonormal basis matrix.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of Q2. LDQ2 >= M2.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dorbdb5*.

4.17.592 sorbdb6

sorbdb6 orthogonalizes the column vector

```
X = [ X1 ]
    [ X2 ]
```

with respect to the columns of

```
Q = [ Q1 ] .
    [ Q2 ]
```

The columns of Q must be orthonormal.

If the projection is zero according to Kahan's "twice is enough" criterion, then the zero vector is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorbdb6(M1, M2, N, X1, INCX1, X2, INCX2, Q1, LDQ1, Q2, LDQ2, WORK,
                   LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorbdb6_(const armpl_int_t *m1, const armpl_int_t *m2,
              const armpl_int_t *n, float *x1, const armpl_int_t *incx1,
              float *x2, const armpl_int_t *incx2, float *q1,
              const armpl_int_t *ldq1, float *q2, const armpl_int_t *ldq2,
              float *work, const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M1 Input parameter.

M1 is INTEGER

The dimension of X1 and the number of rows in Q1. 0 <= M1.

M2 Input parameter.

M2 is INTEGER

The dimension of X2 and the number of rows in Q2. 0 <= M2.

N Input parameter.

N is INTEGER

The number of columns in Q1 and Q2. 0 <= N.

X1 Input and output parameter.

X1 is REAL

X1 is an array, dimension (M1). On entry, the top part of the vector to be orthogonalized. On exit, the top part of the projected vector.

INCX1 Input parameter.

INCX1 is INTEGER

Increment for entries of X1.

X2 Input and output parameter.

X2 is REAL

X2 is an array, dimension (M2). On entry, the bottom part of the vector to be orthogonalized. On exit, the bottom part of the projected vector.

INCX2 Input parameter.

INCX2 is INTEGER

Increment for entries of X2.

Q1 Input parameter.

Q1 is REAL

Q1 is an array, dimension (LDQ1, N). The top part of the orthonormal basis matrix.

LDQ1 Input parameter.

LDQ1 is INTEGER

The leading dimension of Q1. LDQ1 >= M1.

Q2 Input parameter.

Q2 is REAL

Q2 is an array, dimension (LDQ2, N). The bottom part of the orthonormal basis matrix.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of Q2. LDQ2 >= M2.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dorbdb6*.

4.17.593 sorg2l

sorg2l generates an m by n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by SGEQLF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorg2l(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorg2l_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             float *a, const armpl_int_t *lda, const float *tau, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGEQLF in the last k columns of its array argument A. On exit, the m by n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *dorg2l*.

4.17.594 sorg2r

sorg2r generates an m by n real matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by SGEQRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorg2r(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorg2r_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             float *a, const armpl_int_t *lda, const float *tau, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGEQRF in the first k columns of its array argument A. On exit, the m-by-n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQRF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *dorg2r*.

4.17.595 sorgl2

`sorgl2` generates an m by n real matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by SGELQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorgl2(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorgl2_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             float *a, const armpl_int_t *lda, const float *tau, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix Q. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix Q. `N` >= `M`.

K Input parameter.

`K` is `INTEGER`

The number of elementary reflectors whose product defines the matrix Q. `M` >= `K` >= 0.

A Input and output parameter.

`A` is `REAL`

`A` is an array, dimension (`LDA`, `N`). On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGELQF in the first k rows of its array argument `A`. On exit, the m-by-n matrix Q.

LDA Input parameter.

`LDA` is `INTEGER`

The first dimension of the array `A`. `LDA` >= max(1, `M`).

TAU Input parameter.

`TAU` is `REAL`

`TAU` is an array, dimension (`K`). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *dorgl2*.

4.17.596 sorgr2

sorgr2 generates an m by n real matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by SGERQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorgr2(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorgr2_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             float *a, const armpl_int_t *lda, const float *tau, float *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGERQF in the last k rows of its array argument A. On exit, the m by n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *dorgr2*.

4.17.597 sorm2l

sorm2l overwrites the general real m by n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**T * C  if SIDE = 'L' and TRANS = 'T', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**T if SIDE = 'R' and TRANS = 'T',
```

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by SGEQLF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine sorm2l(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorm2l_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const float *a,
             const armpl_int_t *lda, const float *tau, float *c,
             const armpl_int_t *ldc, float *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left = 'R': apply Q or Q^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'T': apply Q^T (Transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGEQLF in the last k columns of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

             const armpl_int_t *ldc, float *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left = 'R': apply Q or Q^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'T': apply Q^T (Transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by SGEQRF in the first k columns of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQRF.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

```

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by STZRZF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine sormr3(SIDE, TRANS, M, N, K, L, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sormr3_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const armpl_int_t *l,
             const float *a, const armpl_int_t *lda, const float *tau,
             float *c, const armpl_int_t *ldc, float *work, armpl_int_t *info,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left = 'R': apply Q or Q^T from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'T': apply Q^T (Transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

A Input parameter.

A is REAL

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by STZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by STZRZF.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dormr3*.

4.17.602 spbtf2

spbtf2 computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

```
A = U**T * U ,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix, U^T is the transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine spbtf2(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void spbtf2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             float *ab, const armpl_int_t *ldab, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpbtf2*, *dpbtf2* and *zpbtf2*.

4.17.603 spotf2

spotf2 computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

```
A = U**T * U ,  if UPLO = 'U', or
A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine spotf2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void spotf2_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpotf2*, *dpotf2* and *zpotf2*.

4.17.604 spstf2

spstf2 computes the Cholesky factorization with complete pivoting of a real symmetric positive semidefinite matrix A.

The factorization has the form

```
P**T * A * P = U**T * U ,  if UPLO = 'U',
P**T * A * P = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector PIV.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine spstf2(UPLO, N, A, LDA, PIV, RANK, TOL, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void spstf2_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *piv, armpl_int_t *rank,
             const float *tol, float *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization as above.

PIV Output parameter.

PIV is INTEGER array, dimension (N)

PIV is such that the nonzero entries are P(PIV(K), K) = 1.

RANK Output parameter.

RANK is INTEGER

The rank of A given by the number of steps the algorithm completed.

TOL Input parameter.

TOL is REAL

User defined tolerance. If TOL < 0, then N*U*MAX(A(K,K)) will be used. The algorithm terminates at the (K-1)st step if the pivot <= TOL.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N). Work space.

INFO Output parameter.

INFO is INTEGER

< 0: If INFO = -K, the K-th argument had an illegal value, = 0: algorithm completed successfully, and > 0: the matrix A is either rank deficient with computed rank as returned in RANK, or is not positive semidefinite. See Section 7 of LAPACK Working Note #161 for further information.

Related Information

For this routine in other precisions, please see *cpstf2*, *dpstf2* and *zpstf2*.

4.17.605 sptts2

sptts2 solves a tridiagonal system of the form

```
A * X = B
```

using the L*D*L^T factorization of A computed by SPTTRF. D is a diagonal matrix specified in the vector D, L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E, and X and B are N by NRHS matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine sptts2(N, NRHS, D, E, B, LDB)
```

C specification:

```
#include "armpl.h"

void sptts2_(const armpl_int_t *n, const armpl_int_t *nrhs, const float *d,
             const float *e, float *b, const armpl_int_t *ldb);
```

Parameters

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the L*D*L^T factorization of A.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L^T factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization A = U^T *D*U.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Related Information

For this routine in other precisions, please see *cptts2*, *dptts2* and *zptts2*.

4.17.606 srscl

srscl multiplies an n-element real vector x by the real scalar 1/a. This is done without overflow or underflow as long as the final result x/a does not overflow or underflow.

Syntax

Fortran specification:

```
use armpl_library

subroutine srscl(N, SA, SX, INCX)
```

C specification:

```
#include "armpl.h"

void srscl_(const armpl_int_t *n, const float *sa, float *sx,
            const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of components of the vector x.

SA Input parameter.

SA is REAL

The scalar a which is used to divide each component of x. SA must be >= 0, or the subroutine will divide by zero.

SX Input and output parameter.

SX is REAL

SX is an array, dimension. (1+(N-1)*abs(INCX)) The n-element vector x.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of the vector SX. > 0: SX(1) = X(1) and SX(1+(i-1)*INCX) = x(i), 1< i<= n

Related Information

For this routine in other precisions, please see *drscl*.

4.17.607 ssfrk

Level 3 BLAS like routine for C in RFP Format.

ssfrk performs one of the symmetric rank–k operations

```
C := alpha*A*A**T + beta*C,
```

or

```
C := alpha*A**T*A + beta*C,
```

where alpha and beta are real scalars, C is an n–by–n symmetric matrix and A is an n–by–k matrix in the first case and a k–by–n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssfrk(TRANSR, UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C)
```

C specification:

```
#include "armpl.h"

void ssfrk_(const char *transr, const char *uplo, const char *trans,
            const armpl_int_t *n, const armpl_int_t *k, const float *alpha,
            const float *a, const armpl_int_t *lda, const float *beta,
            float *c, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal Form of RFP A is stored; = 'T': The Transpose Form of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*A^T + beta*C.

TRANS = 'T' or 't' C := alpha*A^T * A + beta*C.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is REAL

A is an array, dimension (LDA,ka). where KA is K when TRANS = 'N' or 'n', and is N otherwise. Before entry with TRANS = 'N' or 'n', the leading N–by–K part of the array A must contain the matrix A, otherwise the leading K–by–N part of the array A must contain the matrix A. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. Unchanged on exit.

C Input and output parameter.

C is REAL

C is an array, dimension (NT). NT = N*(N+1)/2. On entry, the symmetric matrix C in RFP Format. RFP Format is described by TRANSR, UPLO and N.

Related Information

For this routine in other precisions, please see *dsfrk*. It also exists with a native C interface as *LAPACKE_ssfrk*.

4.17.608 ssyconv

ssyconv convert A given by TRF into L and D and vice-versa. Get Non-diag elements of D (returned in workspace) and apply or reverse permutation done in TRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyconv(UPLO, WAY, N, A, LDA, IPIV, E, INFO)
```

C specification:

```
#include "armpl.h"

void ssyconv_(const char *uplo, const char *way, const armpl_int_t *n,
              float *a, const armpl_int_t *lda, const armpl_int_t *ipiv,
              float *e, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

E Output parameter.

E is REAL

E is an array, dimension (N). E stores the supdiagonal/subdiagonal of the symmetric 1-by-1 or 2-by-2 block diagonal matrix D in LDLT.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyconv*, *dsyconv* and *zsyconv*. It also exists with a native C interface as *LAPACKE_ssyconv*.

4.17.609 ssygs2

ssygs2 reduces a real symmetric-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^T or L^T*A*L.

B must have been previously factorized as U^T*U or L*L^T by SPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssygs2(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ssygs2_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             float *a, const armpl_int_t *lda, const float *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

= 1: compute inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T); = 2 or 3: compute U*A*U^T or L^T*A*L.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored, and how B has been factorized. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is REAL

B is an array, dimension (LDB, N). The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dsygs2*.

4.17.610 ssyswapr

SSYSWAPR applies an elementary permutation on the rows and the columns of a symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyswapr(UPLO, N, A, LDA, I1, I2)
```

C specification:

```
#include "armpl.h"

void ssyswapr_(const char *uplo, const armpl_int_t *n, float *a,
               const armpl_int_t *lda, const armpl_int_t *i1,
               const armpl_int_t *i2, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

I1 Input parameter.

I1 is INTEGER

Index of the first row to swap

I2 Input parameter.

I2 is INTEGER

Index of the second row to swap

Related Information

For this routine in other precisions, please see *csyswapr*, *dsyswapr* and *zsyswapr*. It also exists with a native C interface as *LAPACKE_ssyswapr*.

4.17.611 ssytd2

ssytd2 reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: Q^T * A * Q = T.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytd2(UPLO, N, A, LDA, D, E, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void ssytd2_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *d, float *e, float *tau,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dsytd2*.

4.17.612 ssytf2

ssytf2 computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^T is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytf2(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void ssytf2_(const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of

A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csytf2*, *dsytf2* and *zsytf2*.

4.17.613 ssytf2_rook

SSYTF2_ROOK computes the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^T is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytf2_rook(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void ssytf2_rook_(const char *uplo, const armpl_int_t *n, float *a,
                  const armpl_int_t *lda, armpl_int_t *ipiv,
                  armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

4.17.614 stfsm

Level 3 BLAS like routine for A in RFP Format.

`stfsm` solves the matrix equation

```
op( A )*X = alpha*B  or  X*op( A ) = alpha*B
```

where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**T.
```

A is in Rectangular Full Packed (RFP) Format.

The matrix X is overwritten on B.

Syntax

Fortran specification:

```
use armpl_library

subroutine stfsm(TRANSR, SIDE, UPLO, TRANS, DIAG, M, N, ALPHA, A, B, LDB)
```

C specification:

```
#include "armpl.h"

void stfsm_(const char *transr, const char *side, const char *uplo,
            const char *trans, const char *diag, const armpl_int_t *m,
            const armpl_int_t *n, const float *alpha, const float *a,
            float *b, const armpl_int_t *ldb, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal Form of RFP A is stored; = 'T': The Transpose Form of RFP A is stored.

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l' op(A)*X = alpha*B.

SIDE = 'R' or 'r' X*op(A) = alpha*B.

Unchanged on exit.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the RFP matrix A came from an upper or lower triangular matrix as follows: UPLO = 'U' or 'u' RFP A came from an upper triangular matrix UPLO = 'L' or 'l' RFP A came from a lower triangular matrix

Unchanged on exit.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANS = 'N' or 'n' op(A) = A.

TRANS = 'T' or 't' op(A) = A'.

Unchanged on exit.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not RFP A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A Input parameter.

A is REAL

A is an array, dimension (NT). NT = N*(N+1)/2. On entry, the matrix A in RFP Format. RFP Format is described by TRANSR, UPLO and N as follows: If TRANSR='N' then RFP A is (0:N,0:K-1) when N is even; K=N/2. RFP A is (0:N-1,0:K) when N is odd; K=N/2. If TRANSR = 'T' then RFP is the transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the NT elements of upper packed A either in normal or transpose Format. If UPLO = 'L' the RFP A contains the NT elements of lower packed A either in normal or transpose Format. The LDA of RFP A is (N+1)/2 when TRANSR = 'T'. When TRANSR is 'N' the LDA is N+1 when N is even and is N when is odd. See the Note below for more details. Unchanged on exit.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m). Unchanged on exit.

Related Information

For this routine in other precisions, please see *ctfsm*, *dtfsm* and *ztfsm*. It also exists with a native C interface as *LAPACKE_stfsm*.

4.17.615 stfttp

stfttp copies a triangular matrix A from rectangular full packed format (TF) to standard packed format (TP).

Syntax

Fortran specification:

```
use armpl_library

subroutine stfttp(TRANSR, UPLO, N, ARF, AP, INFO)
```

C specification:

```
#include "armpl.h"

void stfttp_(const char *transr, const char *uplo, const armpl_int_t *n,
             const float *arf, float *ap, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF is in Normal format; = 'T': ARF is in Transpose format;

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ARF Input parameter.

ARF is REAL

ARF is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

AP Output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctfttp*, *dtfttp* and *ztfttp*. It also exists with a native C interface as *LAPACKE_stfttp*.

4.17.616 stfttr

stfttr copies a triangular matrix A from rectangular full packed format (TF) to standard full format (TR).

Syntax

Fortran specification:

```
use armpl_library

subroutine stfttr(TRANSR, UPLO, N, ARF, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void stfttr_(const char *transr, const char *uplo, const armpl_int_t *n,
             const float *arf, float *a, const armpl_int_t *lda,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF is in Normal format; = 'T': ARF is in Transpose format.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrices ARF and A. N >= 0.

ARF Input parameter.

ARF is REAL

ARF is an array, dimension (N*(N+1)/2).. On entry, the upper (if UPLO = 'U') or lower (if UPLO = 'L') matrix A in RFP format. See the "Notes" below for more details.

A Output parameter.

A is REAL

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is

not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctfttr*, *dtfttr* and *ztfttr*. It also exists with a native C interface as *LAPACKE_stfttr*.

4.17.617 stgex2

stgex2 swaps adjacent diagonal blocks (A11, B11) and (A22, B22) of size 1-by-1 or 2-by-2 in an upper (quasi) triangular matrix pair (A, B) by an orthogonal equivalence transformation.

(A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)**T = Q(out) * A(out) * Z(out)**T
Q(in) * B(in) * Z(in)**T = Q(out) * B(out) * Z(out)**T
```

Syntax

Fortran specification:

```
use armpl_library

subroutine stgex2(WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, J1, N1, N2,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void stgex2_(const armpl_int_t *wantq, const armpl_int_t *wantz,
             const armpl_int_t *n, float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, float *q, const armpl_int_t *ldq,
             float *z, const armpl_int_t *ldz, const armpl_int_t *j1,
             const armpl_int_t *n1, const armpl_int_t *n2, float *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, the updated matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, the updated matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. Not referenced if WANTQ = .FALSE..

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, if WANTZ =.TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. Not referenced if WANTZ = .FALSE..

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

J1 Input parameter.

J1 is INTEGER

The index to the first block (A11, B11). 1 <= J1 <= N.

N1 Input parameter.

N1 is INTEGER

The order of the first block (A11, B11). N1 = 0, 1 or 2.

N2 Input parameter.

N2 is INTEGER

The order of the second block (A22, B22). N2 = 0, 1 or 2.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= MAX(N*(N2+N1), (N2+N1)*(N2+N1)*2)

INFO Output parameter.

INFO is INTEGER

=0: Successful exit >0: If INFO = 1, the transformed matrix (A, B) would be too far from generalized Schur form; the blocks are not swapped and (A, B) and (Q, Z) are unchanged. The problem of swapping is too ill-conditioned. <0: If INFO = -16: LWORK is too small. Appropriate value for LWORK is returned in WORK(1).

Related Information

For this routine in other precisions, please see *ctgex2*, *dtgex2* and *ztgex2*.

4.17.618 stgsy2

stgsy2 solves the generalized Sylvester equation:

```
A * R - L * B = scale * C                (1)
D * R - L * E = scale * F,
```

using Level 1 and 2 BLAS. where R and L are unknown M-by-N matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size M-by-M, N-by-N and M-by-N, respectively, with real entries. (A, D) and (B, E) must be in generalized Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular. The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation solving equation (1) corresponds to solve Z*x = scale*b, where Z is defined as

```
Z = [ kron(In, A)  -kron(B**T, Im) ]             (2)
    [ kron(In, D)  -kron(E**T, Im) ],
```

Ik is the identity matrix of size k and X^T is the transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y. In the process of solving (1), we solve a number of such systems where Dim(In), Dim(In) = 1 or 2.

If TRANS = 'T', solve the transposed system Z^T *y = scale*b for y, which is equivalent to solve for R and L in

```
A**T * R  + D**T * L   = scale * C           (3)
R  * B**T + L  * E**T  = scale * -F
```

This case is used to compute an estimate of Dif[(A, D), (B, E)] = sigma_min(Z) using reverse communicaton with SLACON.

stgsy2 also (IJOB >= 1) contributes to the computation in STGSYL of an upper bound on the separation between to matrix pairs. Then the input (A, D), (B, E) are sub-pencils of the matrix pair in STGSYL. See STGSYL for details.

Syntax

Fortran specification:

```
use armpl_library

subroutine stgsy2(TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD, E, LDE,
                  F, LDF, SCALE, RDSUM, RDSCAL, IWORK, PQ, INFO)
```

C specification:

```
#include "armpl.h"

void stgsy2_(const char *trans, const armpl_int_t *ijob, const armpl_int_t *m,
             const armpl_int_t *n, const float *a, const armpl_int_t *lda,
             const float *b, const armpl_int_t *ldb, float *c,
             const armpl_int_t *ldc, const float *d, const armpl_int_t *ldd,
             const float *e, const armpl_int_t *lde, float *f,
             const armpl_int_t *ldf, float *scale, float *rdsum,
             float *rdscal, armpl_int_t *iwork, armpl_int_t *pq,
             armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N', solve the generalized Sylvester equation (1). = 'T': solve the 'transposed' system (3).

IJOB Input parameter.

IJOB is INTEGER

Specifies what kind of functionality to be performed. = 0: solve (1) only. = 1: A contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed. (look ahead strategy is used). = 2: A contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed. (SGECON on sub-systems is used.) Not referenced if TRANS = 'T'.

M Input parameter.

M is INTEGER

On entry, M specifies the order of A and D, and the row dimension of C, F, R and L.

N Input parameter.

N is INTEGER

On entry, N specifies the order of B and E, and the column dimension of C, F, R and L.

A Input parameter.

A is REAL

A is an array, dimension (LDA, M). On entry, A contains an upper quasi triangular matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the matrix A. LDA >= max(1, M).

B Input parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, B contains an upper quasi triangular matrix.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the matrix B. LDB >= max(1, N).

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, C contains the right-hand-side of the first matrix equation in (1). On exit, if IJOB = 0, C has been overwritten by the solution R.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the matrix C. LDC >= max(1, M).

D Input parameter.

D is REAL

D is an array, dimension (LDD, M). On entry, D contains an upper triangular matrix.

LDD Input parameter.

LDD is INTEGER

The leading dimension of the matrix D. LDD >= max(1, M).

E Input parameter.

E is REAL

E is an array, dimension (LDE, N). On entry, E contains an upper triangular matrix.

LDE Input parameter.

LDE is INTEGER

The leading dimension of the matrix E. LDE >= max(1, N).

F Input and output parameter.

F is REAL

F is an array, dimension (LDF, N). On entry, F contains the right-hand-side of the second matrix equation in (1). On exit, if IJOB = 0, F has been overwritten by the solution L.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the matrix F. LDF >= max(1, M).

SCALE Output parameter.

SCALE is REAL

On exit, 0 <= SCALE <= 1. If 0 < SCALE < 1, the solutions R and L (C and F on entry) will hold the solutions to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If SCALE = 0, R and L will hold the solutions to the homogeneous system with C = F = 0. Normally, SCALE = 1.

RDSUM Input and output parameter.

RDSUM is REAL

On entry, the sum of squares of computed contributions to the Dif-estimate under computation by STGSYL, where the scaling factor RDSCAL (see below) has been factored out. On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If TRANS = 'T' RDSUM is not touched. NOTE: RDSUM only makes sense when STGSY2 is called by STGSYL.

RDSCAL Input and output parameter.

RDSCAL is REAL

On entry, scaling factor used to prevent overflow in RDSUM. On exit, RDSCAL is updated w.r.t. the current contributions in RDSUM. If TRANS = 'T', RDSCAL is not touched. NOTE: RDSCAL only makes sense when STGSY2 is called by STGSYL.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M+N+2)

PQ Output parameter.

PQ is INTEGER

On exit, the number of subsystems (of size 2-by-2, 4-by-4 and 8-by-8) solved by this routine.

INFO Output parameter.

INFO is INTEGER

On exit, if INFO is set to =0: Successful exit <0: If INFO = -i, the i-th argument had an illegal value. >0: The matrix pairs (A, D) and (B, E) have common or very close eigenvalues.

Related Information

For this routine in other precisions, please see *ctgsy2*, *dtgsy2* and *ztgsy2*.

4.17.619 stplqt2

stplqt2 computes a LQ a factorization of a real "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine stplqt2(M, N, L, A, LDA, B, LDB, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void stplqt2_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *l, float *a, const armpl_int_t *lda,
              float *b, const armpl_int_t *ldb, float *t,
              const armpl_int_t *ldt, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The total number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the lower trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, M). On entry, the lower triangular M-by-M matrix A. On exit, the elements on and below the diagonal of the array contain the lower triangular matrix L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first N-L columns are rectangular, and the last L columns are lower trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (LDT, M). The N-by-N upper triangular factor T of the block reflector. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, M)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctplqt2*, *dtplqt2* and *ztplqt2*.

4.17.620 stpqrt2

stpqrt2 computes a QR factorization of a real "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine stpqrt2(M, N, L, A, LDA, B, LDB, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void stpqrt2_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *l, float *a, const armpl_int_t *lda,
              float *b, const armpl_int_t *ldb, float *t,
              const armpl_int_t *ldt, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The total number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the upper trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the upper triangular N-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first M-L rows are rectangular, and the last L rows are upper trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is REAL

T is an array, dimension (LDT, N). The N-by-N upper triangular factor T of the block reflector. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpqrt2*, *dtpqrt2* and *ztpqrt2*. It also exists with a native C interface as *LAPACKE_stpqrt2*.

4.17.621 stprfb

stprfb applies a real "triangular-pentagonal" block reflector H or its conjugate transpose H^H to a real matrix C, which is composed of two blocks A and B, either from the left or right.

Syntax

Fortran specification:

```
use armpl_library

subroutine stprfb(SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV, T, LDT, A,
                  LDA, B, LDB, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void stprfb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l, const float *v,
             const armpl_int_t *ldv, const float *t, const armpl_int_t *ldt,
             float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, float *work, const armpl_int_t *ldwork,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^H from the Left = 'R': apply H or H^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'C': apply H^H (Conjugate transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columns = 'R': Rows

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The order of the matrix T, i.e. the number of elementary reflectors whose product defines the block reflector. K >= 0.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

V Input parameter.

V is REAL

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, M) if STOREV = 'R' and SIDE = 'L' (LDV, N) if STOREV = 'R' and SIDE = 'R' The pentagonal matrix V, which contains the elementary reflectors H(1), H(2), . . . , H(K). See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C' and SIDE = 'L', LDV >= max(1, M); if STOREV = 'C' and SIDE = 'R', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

T Input parameter.

T is REAL

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

A Input and output parameter.

A is REAL

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of H*C or H^H*C or C*H or C*H^H. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of H*C or H^H*C or C*H or C*H^H. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension. (LDWORK, N) if SIDE = 'L', (LDWORK, K) if SIDE = 'R'.

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= K; if SIDE = 'R', LDWORK >= M.

Related Information

For this routine in other precisions, please see *ctprfb*, *dtprfb* and *ztprfb*. It also exists with a native C interface as *LAPACKE_stprfb*.

4.17.622 stpttf

stpttf copies a triangular matrix A from standard packed format (TP) to rectangular full packed format (TF).

Syntax

Fortran specification:

```
use armpl_library

subroutine stpttf(TRANSR, UPLO, N, AP, ARF, INFO)
```

C specification:

```
#include "armpl.h"

void stpttf_(const char *transr, const char *uplo, const armpl_int_t *n,
             const float *ap, float *arf, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF in Normal format is wanted; = 'T': ARF in Conjugate-transpose format is wanted.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

ARF Output parameter.

ARF is REAL

ARF is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpttf*, *dtpttf* and *ztpttf*. It also exists with a native C interface as *LAPACKE_stpttf*.

4.17.623 stpttr

stpttr copies a triangular matrix A from standard packed format (TP) to standard full format (TR).

Syntax

Fortran specification:

```
use armpl_library

subroutine stpttr(UPLO, N, AP, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void stpttr_(const char *uplo, const armpl_int_t *n, const float *ap,
             float *a, const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular. = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

A Output parameter.

A is REAL

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpttr*, *dtpttr* and *ztpttr*. It also exists with a native C interface as *LAPACKE_stpttr*.

4.17.624 strti2

strti2 computes the inverse of a real upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine strti2(UPLO, DIAG, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void strti2_(const char *uplo, const char *diag, const armpl_int_t *n,
             float *a, const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrti2*, *dtrti2* and *ztrti2*.

4.17.625 strttf

strttf copies a triangular matrix A from standard full format (TR) to rectangular full packed format (TF) .

Syntax

Fortran specification:

```
use armpl_library

subroutine strttf(TRANSR, UPLO, N, A, LDA, ARF, INFO)
```

C specification:

```
#include "armpl.h"

void strttf_(const char *transr, const char *uplo, const armpl_int_t *n,
             const float *a, const armpl_int_t *lda, float *arf,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF in Normal form is wanted; = 'T': ARF in Transpose form is wanted.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N).. On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the matrix A. LDA >= max(1, N).

ARF Output parameter.

ARF is REAL

ARF is an array, dimension (NT).. NT=N*(N+1)/2. On exit, the triangular matrix A in RFP format.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrttf*, *dtrttf* and *ztrttf*. It also exists with a native C interface as *LAPACKE_strttf*.

4.17.626 strttp

strttp copies a triangular matrix A from full format (TR) to standard packed format (TP).

Syntax

Fortran specification:

```
use armpl_library

subroutine strttp(UPLO, N, A, LDA, AP, INFO)
```

C specification:

```
#include "armpl.h"

void strttp_(const char *uplo, const armpl_int_t *n, const float *a,
             const armpl_int_t *lda, float *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular. = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrices AP and A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AP Output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On exit, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrttp*, *dtrttp* and *ztrttp*. It also exists with a native C interface as *LAPACKE_strttp*.

4.17.627 zdrscl

zdrscl multiplies an n-element complex vector x by the real scalar 1/a. This is done without overflow or underflow as long as the final result x/a does not overflow or underflow.

Syntax

Fortran specification:

```
use armpl_library

subroutine zdrscl(N, SA, SX, INCX)
```

C specification:

```
#include "armpl.h"

void zdrscl_(const armpl_int_t *n, const double *sa,
             armpl_doublecomplex_t *sx, const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of components of the vector x.

SA Input parameter.

SA is DOUBLE PRECISION

The scalar a which is used to divide each component of x. SA must be >= 0, or the subroutine will divide by zero.

SX Input and output parameter.

SX is COMPLEX*16

SX is an array, dimension. (1+(N-1)*abs(INCX)) The n-element vector x.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of the vector SX. > 0: SX(1) = X(1) and SX(1+(i-1)*INCX) = x(i), 1< i<= n

Related Information

4.17.628 zgbtf2

zgbtf2 computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbtf2(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zgbtf2_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
```

(continues on next page)

(continued from previous page)

```
            armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
            armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgbtf2*, *dgbtf2* and *sgbtf2*.

4.17.629 zgebd2

`zgebd2` reduces a complex general m by n matrix A to upper or lower real bidiagonal form B by a unitary transformation: Q^H * A * P = B.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgebd2(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgebd2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda, double *d,
             double *e, armpl_doublecomplex_t *tauq,
             armpl_doublecomplex_t *taup, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns in the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the m by n general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (min(M, N)-1). The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,. . . ,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,. . . ,m-1.

TAUQ Output parameter.

TAUQ is COMPLEX*16

TAUQ is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP Output parameter.

TAUP is COMPLEX*16

TAUP is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (max(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebd2*, *dgebd2* and *sgebd2*.

4.17.630 zgehd2

zgehd2 reduces a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation: $Q^H * A * Q = H$.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgehd2(N, ILO, IHI, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgehd2_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to ZGEBAL; otherwise they should be set to 1 and N respectively. See Further Details. 1 <= ILO <= IHI <= max(1, N).

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the n by n general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgehd2*, *dgehd2* and *sgehd2*.

4.17.631 zgelq2

zgelq2 computes an LQ factorization of a complex m by n matrix A: A = L * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgelq2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgelq2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and below the diagonal of the array contain the m by min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelq2*, *dgelq2* and *sgelq2*. It also exists with a native C interface as *LAPACKE_zgelq2*.

4.17.632 zgelqt3

DGELQT3 recursively computes a LQ factorization of a complex M-by-N matrix A, using the compact WY representation of Q.

Based on the algorithm of Elmroth and Gustavson, IBM J. Res. Develop. Vol 44 No. 4 July 2000.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine zgelqt3(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void zgelqt3_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_doublecomplex_t *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M =< N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the real M-by-N matrix A. On exit, the elements on and below the diagonal contain the N-by-N lower triangular matrix L; the elements above the diagonal are the rows of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgelqt3*, *dgelqt3* and *sgelqt3*.

4.17.633 zgeql2

zgeql2 computes a QL factorization of a complex m by n matrix A: A = Q * L.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeql2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeql2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the n by n lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the m by n lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeql2*, *dgeql2* and *sgeql2*.

4.17.634 zgeqr2

zgeqr2 computes a QR factorization of a complex m by n matrix A: A = Q * R.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeqr2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqr2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and above the diagonal of the array contain the min(m,n) by n upper trapezoidal matrix R (R is upper triangular if m >=

n); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqr2*, *dgeqr2* and *sgeqr2*. It also exists with a native C interface as *LAPACKE_zgeqr2*.

4.17.635 zgeqr2p

zgeqr2p computes a QR factorization of a complex m by n matrix A: A = Q * R. The diagonal entries of R are real and nonnegative.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeqr2p(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqr2p_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and above the diagonal of the array contain the min(m,n) by n upper trapezoidal matrix R (R is upper triangular if m >= n). The diagonal entries of R are real and nonnegative; the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqr2p*, *dgeqr2p* and *sgeqr2p*.

4.17.636 zgeqrt2

zgeqrt2 computes a QR factorization of a complex M-by-N matrix A, using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeqrt2(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqrt2_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_doublecomplex_t *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the complex M-by-N matrix A. On exit, the elements on and above the diagonal contain the N-by-N upper triangular matrix R; the elements below the diagonal are the columns of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrt2*, *dgeqrt2* and *sgeqrt2*. It also exists with a native C interface as *LAPACKE_zgeqrt2*.

4.17.637 zgeqrt3

zgeqrt3 recursively computes a QR factorization of a complex M-by-N matrix A, using the compact WY representation of Q.

Based on the algorithm of Elmroth and Gustavson, IBM J. Res. Develop. Vol 44 No. 4 July 2000.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine zgeqrt3(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void zgeqrt3_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_doublecomplex_t *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the complex M-by-N matrix A. On exit, the elements on and above the diagonal contain the N-by-N upper triangular matrix R; the elements below the diagonal are the columns of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgeqrt3*, *dgeqrt3* and *sgeqrt3*. It also exists with a native C interface as *LAPACKE_zgeqrt3*.

4.17.638 zgerq2

zgerq2 computes an RQ factorization of a complex m by n matrix A: A = R * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgerq2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgerq2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the m by m upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the m by n upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgerq2*, *dgerq2* and *sgerq2*.

4.17.639 zgesc2

zgesc2 solves a system of linear equations

```
A * X = scale* RHS
```

with a general N-by-N matrix A using the LU factorization with complete pivoting computed by ZGETC2.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgesc2(N, A, LDA, RHS, IPIV, JPIV, SCALE)
```

C specification:

```
#include "armpl.h"

void zgesc2_(const armpl_int_t *n, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *rhs,
             const armpl_int_t *ipiv, const armpl_int_t *jpiv,
             double *scale);
```

Parameters

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the LU part of the factorization of the n-by-n matrix A computed by ZGETC2: A = P * L * U * Q

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

RHS Input and output parameter.

RHS is COMPLEX*16

RHS is an array, dimension N.. On entry, the right hand side vector b. On exit, the solution vector X.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Input parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

SCALE Output parameter.

SCALE is DOUBLE PRECISION

On exit, SCALE contains the scale factor. SCALE is chosen 0 <= SCALE <= 1 to prevent owerflow in the solution.

Related Information

For this routine in other precisions, please see *cgesc2*, *dgesc2* and *sgesc2*.

4.17.640 zgetc2

zgetc2 computes an LU factorization, using complete pivoting, of the n-by-n matrix A. The factorization has the form A = P * L * U * Q, where P and Q are permutation matrices, L is lower triangular with unit diagonal elements and U is upper triangular.

This is a level 1 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgetc2(N, A, LDA, IPIV, JPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zgetc2_(const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *jpiv,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the n-by-n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U*Q; the unit diagonal elements of L are not stored. If U(k, k) appears to be less than SMIN, U(k, k) is given the value of SMIN, giving a nonsingular perturbed system.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Output parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, U(k, k) is likely to produce overflow if one tries to solve for x in Ax = b. So U is perturbed to avoid the overflow.

Related Information

For this routine in other precisions, please see *cgetc2*, *dgetc2* and *sgetc2*.

4.17.641 zgetf2

zgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 2 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgetf2(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zgetf2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *cgetf2*, *dgetf2* and *sgetf2*. It also exists with a native C interface as *LAPACKE_zgetf2*.

4.17.642 zgsvj0

zgsvj0 is called from ZGESVJ as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as ZGESVJ does, but it does not check convergence (stopping criterion). Few tuning parameters (marked by [TP]) are available for the implementer.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgsvj0(JOBV, M, N, A, LDA, D, SVA, MV, V, LDV, EPS, SFMIN, TOL,
                  NSWEEP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgsvj0_(const char *jobv, const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *d, double *sva, const armpl_int_t *mv,
             armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             const double *eps, const double *sfmin, const double *tol,
             const armpl_int_t *nsweep, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether the output from this procedure is used to compute the matrix V: = 'V': the product of the Jacobi rotations is accumulated by postmulyiplying the N-by-N array V. (See the description of V.) = 'A': the product of the Jacobi rotations is accumulated by postmulyiplying the MV-by-N array V. (See the descriptions of MV and V.) = 'N': the Jacobi rotations are not accumulated.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, M-by-N matrix A, such that A*diag(D) represents the input matrix. On exit, A_onexit * diag(D_onexit) represents the input matrix A*diag(D) post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of D, TOL and NSWEEP.)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Input and output parameter.

D is COMPLEX*16

D is an array, dimension (N). The array D accumulates the scaling factors from the complex scaled Jacobi rotations. On entry, A*diag(D) represents the input matrix. On exit, A_onexit*diag(D_onexit) represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of A, TOL and NSWEEP.)

SVA Input and output parameter.

SVA is DOUBLE PRECISION

SVA is an array, dimension (N). On entry, SVA contains the Euclidean norms of the columns of the matrix A*diag(D). On exit, SVA contains the Euclidean norms of the columns of the matrix A_onexit*diag(D_onexit).

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then MV is not referenced.

V Input and output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, N). If JOBV .EQ. 'V' then N rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV .EQ. 'A' then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V', LDV .GE. N. If JOBV = 'A', LDV .GE. MV.

EPS Input parameter.

EPS is DOUBLE PRECISION

EPS = DLAMCH('Epsilon')

SFMIN Input parameter.

SFMIN is DOUBLE PRECISION

SFMIN = DLAMCH('Safe Minimum')

TOL Input parameter.

TOL is DOUBLE PRECISION

TOL is the threshold for Jacobi rotations. For a pair A(:,p), A(:,q) of pivot columns, the Jacobi rotation is applied only if ABS(COS(angle(A(:,p),A(:,q)))) .GT. TOL.

NSWEEP Input parameter.

NSWEEP is INTEGER

NSWEEP is the number of sweeps of Jacobi rotations to be performed.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

LWORK is the dimension of WORK. LWORK .GE. M.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgsvj0*, *dgsvj0* and *sgsvj0*.

4.17.643 zgsvj1

zgsvj1 is called from ZGESVJ as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as ZGESVJ does, but it targets only particular pivots and it does not check convergence (stopping criterion). Few tunning parameters (marked by [TP]) are available for the implementer.

Further Details

zgsvj1 applies few sweeps of Jacobi rotations in the column space of the input M-by-N matrix A. The pivot pairs are taken from the (1,2) off-diagonal block in the corresponding N-by-N Gram matrix A^T * A. The block-entries (tiles) of the (1,2) off-diagonal block are marked by the [x]'s in the following scheme:

```
| *  *  * [x] [x] [x]|
| *  *  * [x] [x] [x]|    Row-cycling in the nblr-by-nblc [x] blocks.
| *  *  * [x] [x] [x]|    Row-cyclic pivoting inside each [x] block.
|[x] [x] [x] *  *  * |
|[x] [x] [x] *  *  * |
|[x] [x] [x] *  *  * |
```

In terms of the columns of A, the first N1 columns are rotated 'against' the remaining N-N1 columns, trying to increase the angle between the corresponding subspaces. The off-diagonal block is N1-by(N-N1) and it is tiled using quadratic tiles of side KBL. Here, KBL is a tunning parmeter. The number of sweeps is given in NSWEEP and the orthogonality threshold is given in TOL.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgsvj1(JOBV, M, N, N1, A, LDA, D, SVA, MV, V, LDV, EPS, SFMIN, TOL,
                  NSWEEP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgsvj1_(const char *jobv, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *n1, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *d, double *sva,
             const armpl_int_t *mv, armpl_doublecomplex_t *v,
             const armpl_int_t *ldv, const double *eps, const double *sfmin,
             const double *tol, const armpl_int_t *nsweep,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether the output from this procedure is used to compute the matrix V: = 'V': the product of the Jacobi rotations is accumulated by postmulyiplying the N-by-N array V. (See the description of V.) = 'A': the product of the Jacobi rotations is accumulated by postmulyiplying the MV-by-N array V. (See the descriptions of MV and V.) = 'N': the Jacobi rotations are not accumulated.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

N1 Input parameter.

N1 is INTEGER

N1 specifies the 2 x 2 block partition, the first N1 columns are rotated 'against' the remaining N-N1 columns of A.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, M-by-N matrix A, such that A*diag(D) represents the input matrix. On exit, A_onexit * D_onexit represents the input matrix A*diag(D) post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of N1, D, TOL and NSWEEP.)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Input and output parameter.

D is COMPLEX*16

D is an array, dimension (N). The array D accumulates the scaling factors from the fast scaled Jacobi rotations. On entry, A*diag(D) represents the input matrix. On exit, A_onexit*diag(D_onexit) represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of N1, A, TOL and NSWEEP.)

SVA Input and output parameter.

SVA is DOUBLE PRECISION

SVA is an array, dimension (N). On entry, SVA contains the Euclidean norms of the columns of the matrix A*diag(D). On exit, SVA contains the Euclidean norms of the columns of the matrix onexit*diag(D_onexit).

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then MV is not referenced.

V Input and output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, N). If JOBV .EQ. 'V' then N rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV .EQ. 'A' then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V', LDV .GE. N. If JOBV = 'A', LDV .GE. MV.

EPS Input parameter.

EPS is DOUBLE PRECISION

EPS = DLAMCH('Epsilon')

SFMIN Input parameter.

SFMIN is DOUBLE PRECISION

SFMIN = DLAMCH('Safe Minimum')

TOL Input parameter.

TOL is DOUBLE PRECISION

TOL is the threshold for Jacobi rotations. For a pair A(:,p), A(:,q) of pivot columns, the Jacobi rotation is applied only if ABS(COS(angle(A(:,p),A(:,q)))) .GT. TOL.

NSWEEP Input parameter.

NSWEEP is INTEGER

NSWEEP is the number of sweeps of Jacobi rotations to be performed.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

LWORK is the dimension of WORK. LWORK .GE. M.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgsvj1*, *dgsvj1* and *sgsvj1*.

4.17.644 zgtts2

zgtts2 solves one of the systems of equations

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

with a tridiagonal matrix A using the LU factorization computed by ZGTTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgtts2(ITRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB)
```

C specification:

```
#include "armpl.h"

void zgtts2_(const armpl_int_t *itrans, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_doublecomplex_t *dl,
             const armpl_doublecomplex_t *d, const armpl_doublecomplex_t *du,
             const armpl_doublecomplex_t *du2, const armpl_int_t *ipiv,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb);
```

Parameters

ITRANS Input parameter.

ITRANS is INTEGER

Specifies the form of the system of equations. = 0: A * X = B (No transpose) = 1: A^T * X = B (Transpose) = 2: A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is COMPLEX*16

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input parameter.

D is COMPLEX*16

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is COMPLEX*16

DU is an array, dimension (N-1). The (n-1) elements of the first super-diagonal of U.

DU2 Input parameter.

DU2 is COMPLEX*16

DU2 is an array, dimension (N-2). The (n-2) elements of the second super-diagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Related Information

For this routine in other precisions, please see *cgtts2*, *dgtts2* and *sgtts2*.

4.17.645 zhegs2

zhegs2 reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^H or L^H *A*L.

B must have been previously factorized as U^H *U or L*L^H by ZPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhegs2(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zhegs2_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

= 1: compute inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H); = 2 or 3: compute U*A*U^H or L^H *A*L.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored, and how B has been factorized. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). The triangular factor from the Cholesky factorization of B, as returned by ZPOTRF.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *chegs2*.

4.17.646 zheswapr

ZHESWAPR applies an elementary permutation on the rows and the columns of a hermitian matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheswapr(UPLO, N, A, LDA, I1, I2)
```

C specification:

```
#include "armpl.h"

void zheswapr_(const char *uplo, const armpl_int_t *n,
               armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_int_t *i1, const armpl_int_t *i2, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

I1 Input parameter.

I1 is INTEGER

Index of the first row to swap

I2 Input parameter.

I2 is INTEGER

Index of the second row to swap

Related Information

For this routine in other precisions, please see *cheswapr*. It also exists with a native C interface as *LAPACKE_zheswapr*.

4.17.647 zhetd2

zhetd2 reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^H * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetd2(UPLO, N, A, LDA, D, E, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void zhetd2_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, double *d, double *e,
             armpl_doublecomplex_t *tau, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *chetd2*.

4.17.648 zhetf2

zhetf2 computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^H is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetf2(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zhetf2_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *chetf2*.

4.17.649 zhetf2_rook

ZHETF2_ROOK computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^H is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetf2_rook(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zhetf2_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_doublecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *chetf2_rook*.

4.17.650 zhfrk

Level 3 BLAS like routine for C in RFP Format.

zhfrk performs one of the Hermitian rank–k operations

```
C := alpha*A*A**H + beta*C,
```

or

```
C := alpha*A**H*A + beta*C,
```

where alpha and beta are real scalars, C is an n–by–n Hermitian matrix and A is an n–by–k matrix in the first case and a k–by–n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhfrk(TRANSR, UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C)
```

C specification:

```
#include "armpl.h"

void zhfrk_(const char *transr, const char *uplo, const char *trans,
            const armpl_int_t *n, const armpl_int_t *k, const double *alpha,
            const armpl_doublecomplex_t *a, const armpl_int_t *lda,
            const double *beta, armpl_doublecomplex_t *c, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal Form of RFP A is stored; = 'C': The Conjugate-transpose Form of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*A^H + beta*C.

TRANS = 'C' or 'c' C := alpha*A^H * A + beta*C.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA,ka). where KA is K when TRANS = 'N' or 'n', and is N otherwise. Before entry with TRANS = 'N' or 'n', the leading N–by–K part of the array A must contain the matrix A, otherwise the leading K–by–N part of the array A must contain the matrix A. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION

On entry, BETA specifies the scalar beta. Unchanged on exit.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (N*(N+1)/2). On entry, the matrix A in RFP Format. RFP Format is described by TRANSR, UPLO and N. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Related Information

For this routine in other precisions, please see *chfrk*. It also exists with a native C interface as *LAPACKE_zhfrk*.

4.17.651 zla_gbamv

ZLA_GBAMV performs one of the matrix-vector operations

```
      y := alpha*abs(A)*abs(x) + beta*abs(y),
or    y := alpha*abs(A)**T*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_gbamv(TRANS, M, N, KL, KU, ALPHA, AB, LDAB, X, INCX, BETA, Y,
                     INCY)
```

C specification:

```
#include "armpl.h"

void zla_gbamv_(const armpl_int_t *trans, const armpl_int_t *m,
                const armpl_int_t *n, const armpl_int_t *kl,
                const armpl_int_t *ku, const double *alpha,
                const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
                const armpl_doublecomplex_t *x, const armpl_int_t *incx,
                const double *beta, double *y, const armpl_int_t *incy);
```

Parameters

TRANS Input parameter.

TRANS is INTEGER

On entry, TRANS specifies the operation to be performed as follows:

BLAS_NO_TRANS y := alpha*abs(A)*abs(x) + beta*abs(y) BLAS_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y) BLAS_CONJ_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y)

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, n). Before entry, the leading m by n part of the array AB must contain the matrix of coefficients. Unchanged on exit.

LDAB Input parameter.

LDAB is INTEGER

On entry, LDAB specifies the first dimension of AB as declared in the calling (sub) program. LDAB must be at least max(1, m). Unchanged on exit.

X Input parameter.

X is COMPLEX*16

X is an array, dimension. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Level 2 Blas routine.

Related Information

For this routine in other precisions, please see *cla_gbamv*, *dla_gbamv* and *sla_gbamv*.

4.17.652 zla_gbrcond_c

```
ZLA_GBRCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_gbrcond_c(TRANS, N, KL, KU, AB, LDAB, AFB,
                                        LDAFB, IPIV, C, CAPPLY, INFO, WORK,
                                        RWORK)
```

C specification:

```
#include "armpl.h"

double zla_gbrcond_c_(const char *trans, const armpl_int_t *n,
                      const armpl_int_t *kl, const armpl_int_t *ku,
                      const armpl_doublecomplex_t *ab,
                      const armpl_int_t *ldab,
                      const armpl_doublecomplex_t *afb,
                      const armpl_int_t *ldafb, const armpl_int_t *ipiv,
                      const double *c, const armpl_int_t *capply,
                      armpl_int_t *info, const armpl_doublecomplex_t *work,
                      const double *rwork, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by ZGBTRF; row i of the matrix was interchanged with row IPIV(i).

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N).. Workspace.

Related Information

For this routine in other precisions, please see *cla_gbrcond_c*.

4.17.653 zla_gbrcond_x

```
ZLA_GBRCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX*16 vector.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_gbrcond_x(TRANS, N, KL, KU, AB, LDAB, AFB,
                                        LDAFB, IPIV, X, INFO, WORK, RWORK)
```

C specification:

```
#include "armpl.h"

double zla_gbrcond_x_(const char *trans, const armpl_int_t *n,
                      const armpl_int_t *kl, const armpl_int_t *ku,
                      const armpl_doublecomplex_t *ab,
                      const armpl_int_t *ldab,
                      const armpl_doublecomplex_t *afb,
                      const armpl_int_t *ldafb, const armpl_int_t *ipiv,
                      const armpl_doublecomplex_t *x, armpl_int_t *info,
                      const armpl_doublecomplex_t *work, const double *rwork,
                      ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by ZGBTRF; row i of the matrix was interchanged with row IPIV(i).

X Input parameter.

X is COMPLEX*16

X is an array, dimension (N). The vector X in the formula op(A) * diag(X).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N).. Workspace.

4.17.654 zla_gbrfsx_extended

zla_gbrfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by ZGBRFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_gbrfsx_extended(PREC_TYPE, TRANS_TYPE, N, KL, KU, NRHS, AB,
                               LDAB, AFB, LDAFB, IPIV, COLEQU, C, B, LDB, Y,
                               LDY, BERR_OUT, N_NORMS, ERR_BNDS_NORM,
                               ERR_BNDS_COMP, RES, AYB, DY, Y_TAIL, RCOND,
                               ITHRESH, RTHRESH, DZ_UB, IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void zla_gbrfsx_extended_(const armpl_int_t *prec_type,
                          const armpl_int_t *trans_type, const armpl_int_t *n,
                          const armpl_int_t *kl, const armpl_int_t *ku,
                          const armpl_int_t *nrhs,
                          const armpl_doublecomplex_t *ab,
                          const armpl_int_t *ldab,
                          const armpl_doublecomplex_t *afb,
                          const armpl_int_t *ldafb, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const double *c,
                          const armpl_doublecomplex_t *b,
                          const armpl_int_t *ldb, armpl_doublecomplex_t *y,
                          const armpl_int_t *ldy, double *berr_out,
                          const armpl_int_t *n_norms, double *err_bnds_norm,
                          double *err_bnds_comp, armpl_doublecomplex_t *res,
                          double *ayb, armpl_doublecomplex_t *dy,
                          armpl_doublecomplex_t *y_tail, const double *rcond,
                          const armpl_int_t *ithresh, const double *rthresh,
                          const double *dz_ub,
                          const armpl_int_t *ignore_cwise,
                          armpl_int_t *info);
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = ‘S’: Single = ‘D’: Double = ‘I’: Indigenous = ‘X’, ‘E’: Extra

TRANS_TYPE Input parameter.

TRANS_TYPE is INTEGER

Specifies the transposition operation on A. The value is defined by ILATRANS(T) where T is a CHARACTER and T = ‘N’: No transpose = ‘T’: Transpose = ‘C’: Conjugate transpose

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the N-by-N matrix A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array A. LDAB >= max(1, N).

AFB Input parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by ZGBTRF.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by ZGBTRF; row i of the matrix was interchanged with row IPIV(i).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by ZGBTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is DOUBLE PRECISION

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by ZLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX*16

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX*16

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX*16

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is DOUBLE PRECISION

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is DOUBLE PRECISION

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to ZGBTRS had an illegal value

Related Information

For this routine in other precisions, please see *cla_gbrfsx_extended*, *dla_gbrfsx_extended* and *sla_gbrfsx_extended*.

4.17.655 zla_gbrpvgrw

ZLA_GBRPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_gbrpvgrw(N, KL, KU, NCOLS, AB, LDAB, AFB,
                                       LDAFB)
```

C specification:

```
#include "armpl.h"

double zla_gbrpvgrw_(const armpl_int_t *n, const armpl_int_t *kl,
                     const armpl_int_t *ku, const armpl_int_t *ncols,
                     const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
                     const armpl_doublecomplex_t *afb,
                     const armpl_int_t *ldafb);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX*16

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

Related Information

For this routine in other precisions, please see *cla_gbrpvgrw*, *dla_gbrpvgrw* and *sla_gbrpvgrw*.

4.17.656 zla_geamv

ZLA_GEAMV performs one of the matrix-vector operations

```
     y := alpha*abs(A)*abs(x) + beta*abs(y),
or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_geamv(TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zla_geamv_(const armpl_int_t *trans, const armpl_int_t *m,
                const armpl_int_t *n, const double *alpha,
                const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                const armpl_doublecomplex_t *x, const armpl_int_t *incx,
                const double *beta, double *y, const armpl_int_t *incy);
```

Parameters

TRANS Input parameter.

TRANS is INTEGER

On entry, TRANS specifies the operation to be performed as follows:

BLAS_NO_TRANS y := alpha*abs(A)*abs(x) + beta*abs(y) BLAS_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y) BLAS_CONJ_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y)

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, n). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m). Unchanged on exit.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Level 2 Blas routine.

Related Information

For this routine in other precisions, please see *cla_geamv*, *dla_geamv* and *sla_geamv*.

4.17.657 zla_gercond_c

```
ZLA_GERCOND_C computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_gercond_c(TRANS, N, A, LDA, AF, LDAF, IPIV, C,
                                        CAPPLY, INFO, WORK, RWORK)
```

C specification:

```
#include "armpl.h"

double zla_gercond_c_(const char *trans, const armpl_int_t *n,
                      const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                      const armpl_doublecomplex_t *af,
                      const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                      const double *c, const armpl_int_t *capply,
                      armpl_int_t *info, const armpl_doublecomplex_t *work,
                      const double *rwork, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by ZGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by ZGETRF; row i of the matrix was interchanged with row IPIV(i).

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N).. Workspace.

4.17.658 zla_gercond_x

```
ZLA_GERCOND_X computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX*16 vector.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_gercond_x(TRANS, N, A, LDA, AF, LDAF, IPIV, X,
                                        INFO, WORK, RWORK)
```

C specification:

```
#include "armpl.h"

double zla_gercond_x_(const char *trans, const armpl_int_t *n,
                      const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                      const armpl_doublecomplex_t *af,
                      const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                      const armpl_doublecomplex_t *x, armpl_int_t *info,
                      const armpl_doublecomplex_t *work, const double *rwork,
                      ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by ZGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by ZGETRF; row i of the matrix was interchanged with row IPIV(i).

X Input parameter.

X is COMPLEX*16

X is an array, dimension (N). The vector X in the formula op(A) * diag(X).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N).. Workspace.

4.17.659 zla_gerfsx_extended

zla_gerfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by ZGERFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERRS_N and ERRS_C for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERRS_N and ERRS_C.

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_gerfsx_extended(PREC_TYPE, TRANS_TYPE, N, NRHS, A, LDA, AF,
                               LDAF, IPIV, COLEQU, C, B, LDB, Y, LDY,
                               BERR_OUT, N_NORMS, ERRS_N, ERRS_C, RES, AYB,
                               DY, Y_TAIL, RCOND, ITHRESH, RTHRESH, DZ_UB,
                               IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void zla_gerfsx_extended_(const armpl_int_t *prec_type,
                          const armpl_int_t *trans_type, const armpl_int_t *n,
                          const armpl_int_t *nrhs,
                          const armpl_doublecomplex_t *a,
                          const armpl_int_t *lda,
                          const armpl_doublecomplex_t *af,
                          const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const double *c,
                          const armpl_doublecomplex_t *b,
                          const armpl_int_t *ldb, armpl_doublecomplex_t *y,
                          const armpl_int_t *ldy, double *berr_out,
                          const armpl_int_t *n_norms, double *errs_n,
                          double *errs_c, armpl_doublecomplex_t *res,
                          double *ayb, armpl_doublecomplex_t *dy,
                          armpl_doublecomplex_t *y_tail, const double *rcond,
                          const armpl_int_t *ithresh, const double *rthresh,
                          const double *dz_ub,
                          const armpl_int_t *ignore_cwise,
                          armpl_int_t *info);
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

TRANS_TYPE Input parameter.

TRANS_TYPE is INTEGER

Specifies the transposition operation on A. The value is defined by ILATRANS(T) where T is a CHARACTER and T = 'N': No transpose = 'T': Transpose = 'C': Conjugate transpose

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by ZGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by ZGETRF; row i of the matrix was interchanged with row IPIV(i).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by ZGETRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is DOUBLE PRECISION

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by ZLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERRS_N and ERRS_C). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERRS_N Input and output parameter.

ERRS_N is DOUBLE PRECISION

ERRS_N is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERRS_N(i,:) corresponds to the ith right-hand side.

The second index in ERRS_N(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERRS_C Input and output parameter.

ERRS_C is DOUBLE PRECISION

ERRS_C is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERRS_C is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERRS_C(i,:) corresponds to the ith right-hand side.

The second index in ERRS_C(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX*16

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX*16

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX*16

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERRS_N and ERRS_C may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is DOUBLE PRECISION

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is DOUBLE PRECISION

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to ZGETRS had an illegal value

Related Information

For this routine in other precisions, please see *cla_gerfsx_extended*, *dla_gerfsx_extended* and *sla_gerfsx_extended*.

4.17.660 zla_gerpvgrw

ZLA_GERPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The “max absolute element” norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_gerpvgrw(N, NCOLS, A, LDA, AF, LDAF)
```

C specification:

```
#include "armpl.h"

double zla_gerpvgrw_(const armpl_int_t *n, const armpl_int_t *ncols,
                     const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                     const armpl_doublecomplex_t *af,
                     const armpl_int_t *ldaf);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by ZGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

Related Information

For this routine in other precisions, please see *cla_gerpvgrw*, *dla_gerpvgrw* and *sla_gerpvgrw*.

4.17.661 zla_heamv

ZLA_SYAMV performs the matrix-vector operation

```
y := alpha*abs(A)*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an n by n symmetric matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_heamv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zla_heamv_(const armpl_int_t *uplo, const armpl_int_t *n,
                const double *alpha, const armpl_doublecomplex_t *a,
                const armpl_int_t *lda, const armpl_doublecomplex_t *x,
                const armpl_int_t *incx, const double *beta, double *y,
                const armpl_int_t *incy);
```

Parameters

UPLO Input parameter.

UPLO is INTEGER

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = BLAS_UPPER Only the upper triangular part of A is to be referenced.

UPLO = BLAS_LOWER Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION .

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, n).. Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n). Unchanged on exit.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION .

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension. (1 + (n - 1)*abs(INCY)) Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Related Information

4.17.662 zla_hercond_c

```
ZLA_HERCOND_C computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_hercond_c(UPLO, N, A, LDA, AF, LDAF, IPIV, C,
                                        CAPPLY, INFO, WORK, RWORK)
```

C specification:

```
#include "armpl.h"

double zla_hercond_c_(const char *uplo, const armpl_int_t *n,
                      const armpl_doublecomplex_t *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                        const armpl_doublecomplex_t *af,
                        const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                        const double *c, const armpl_int_t *capply,
                        armpl_int_t *info, const armpl_doublecomplex_t *work,
                        const double *rwork, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N).. Workspace.

Related Information

```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

X Input parameter.

X is COMPLEX*16

X is an array, dimension (N). The vector X in the formula op(A) * diag(X).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N).. Workspace.

4.17.664 zla_herfsx_extended

zla_herfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by ZHERFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_herfsx_extended(PREC_TYPE, UPLO, N, NRHS, A, LDA, AF, LDAF,
                               IPIV, COLEQU, C, B, LDB, Y, LDY, BERR_OUT,
                               N_NORMS, ERR_BNDS_NORM, ERR_BNDS_COMP, RES,
                               AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
                               DZ_UB, IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void zla_herfsx_extended_(const armpl_int_t *prec_type, const char *uplo,
                          const armpl_int_t *n, const armpl_int_t *nrhs,
                          const armpl_doublecomplex_t *a,
                          const armpl_int_t *lda,
                          const armpl_doublecomplex_t *af,
                          const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const double *c,
                          const armpl_doublecomplex_t *b,
                          const armpl_int_t *ldb, armpl_doublecomplex_t *y,
                          const armpl_int_t *ldy, double *berr_out,
                          const armpl_int_t *n_norms, double *err_bnds_norm,
                          double *err_bnds_comp, armpl_doublecomplex_t *res,
                          double *ayb, armpl_doublecomplex_t *dy,
                          armpl_doublecomplex_t *y_tail, const double *rcond,
                          const armpl_int_t *ithresh, const double *rthresh,
                          const double *dz_ub,
                          const armpl_int_t *ignore_cwise, armpl_int_t *info,
                          ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF.

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by ZHETRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is DOUBLE PRECISION

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by ZLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix

Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX*16

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX*16

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX*16

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is DOUBLE PRECISION

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is DOUBLE PRECISION

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to ZLA_HERFSX_EXTENDED had an illegal value

Related Information

For this routine in other precisions, please see *cla_herfsx_extended*.

4.17.665 zla_herpvgrw

ZLA_HERPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_herpvgrw(UPLO, N, INFO, A, LDA, AF, LDAF, IPIV,
                                       WORK)
```

C specification:

```
#include "armpl.h"

double zla_herpvgrw_(const char *uplo, const armpl_int_t *n,
                     const armpl_int_t *info, const armpl_doublecomplex_t *a,
                     const armpl_int_t *lda, const armpl_doublecomplex_t *af,
                     const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                     double *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

INFO Input parameter.

INFO is INTEGER

The value of INFO returned from ZHETRF, .i.e., the pivot in column INFO is exactly 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF.

WORK Input parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *cla_herpvgrw*.

4.17.666 zla_lin_berr

```
ZLA_LIN_BERR computes componentwise relative backward error from
   the formula
       max(i) ( abs(R(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
   where abs(Z) is the componentwise absolute value of the matrix
   or vector Z.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_lin_berr(N, NZ, NRHS, RES, AYB, BERR)
```

C specification:

```
#include "armpl.h"

void zla_lin_berr_(const armpl_int_t *n, const armpl_int_t *nz,
                   const armpl_int_t *nrhs, const armpl_doublecomplex_t *res,
                   const double *ayb, double *berr);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NZ Input parameter.

NZ is INTEGER

We add (NZ+1)*SLAMCH('Safe minimum') to R(i) in the numerator to guard against spuriously zero residuals. Default value is N.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices AYB, RES, and BERR. NRHS >= 0.

RES Input parameter.

RES is COMPLEX*16

RES is an array, dimension (N, NRHS). The residual matrix, i.e., the matrix R in the relative backward error formula above.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N, NRHS). The denominator in the relative backward error formula above, i.e., the matrix abs(op(A_s))*abs(Y) + abs(B_s). The matrices A, Y, and B are from iterative refinement (see zla_gerfsx_extended.f).

BERR Output parameter.

BERR is DOUBLE PRECISION

BERR is an array, dimension (NRHS). The componentwise relative backward error from the formula above.

Related Information

4.17.667 zla_porcond_c

```
ZLA_PORCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector
```

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_porcond_c(UPLO, N, A, LDA, AF, LDAF, C, CAPPLY,
                                        INFO, WORK, RWORK)
```

C specification:

```
#include "armpl.h"

double zla_porcond_c_(const char *uplo, const armpl_int_t *n,
                      const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                      const armpl_doublecomplex_t *af,
                      const armpl_int_t *ldaf, const double *c,
                      const armpl_int_t *capply, armpl_int_t *info,
                      const armpl_doublecomplex_t *work, const double *rwork,
                      ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by ZPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N).. Workspace.

double zla_porcond_x_(const char *uplo, const armpl_int_t *n,
                      const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                      const armpl_doublecomplex_t *af,
                      const armpl_int_t *ldaf, const armpl_doublecomplex_t *x,
                      armpl_int_t *info, const armpl_doublecomplex_t *work,
                      const double *rwork, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by ZPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

X Input parameter.

X is COMPLEX*16

X is an array, dimension (N). The vector X in the formula op(A) * diag(X).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N).. Workspace.

Related Information

4.17.669 zla_porfsx_extended

zla_porfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by ZPORFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_porfsx_extended(PREC_TYPE, UPLO, N, NRHS, A, LDA, AF, LDAF,
                               COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS,
                               ERR_BNDS_NORM, ERR_BNDS_COMP, RES, AYB, DY,
                               Y_TAIL, RCOND, ITHRESH, RTHRESH, DZ_UB,
                               IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void zla_porfsx_extended_(const armpl_int_t *prec_type, const char *uplo,
                          const armpl_int_t *n, const armpl_int_t *nrhs,
                          const armpl_doublecomplex_t *a,
                          const armpl_int_t *lda,
                          const armpl_doublecomplex_t *af,
                          const armpl_int_t *ldaf, const armpl_int_t *colequ,

                          double *ayb, armpl_doublecomplex_t *dy,
                          armpl_doublecomplex_t *y_tail, const double *rcond,
                          const armpl_int_t *ithresh, const double *rthresh,
                          const double *dz_ub,
                          const armpl_int_t *ignore_cwise, armpl_int_t *info,
                          ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by ZPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by ZPOTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is DOUBLE PRECISION

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by ZLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX*16

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX*16 PRECISION array, dimension (N)

Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX*16

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is DOUBLE PRECISION

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is DOUBLE PRECISION

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to ZPOTRS had an illegal value

Related Information

For this routine in other precisions, please see *cla_porfsx_extended*, *dla_porfsx_extended* and *sla_porfsx_extended*.

4.17.670 zla_porpvgrw

ZLA_PORPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_porpvgrw(UPLO, NCOLS, A, LDA, AF, LDAF, WORK)
```

C specification:

```
#include "armpl.h"

double zla_porpvgrw_(const char *uplo, const armpl_int_t *ncols,
                     const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                     const armpl_doublecomplex_t *af, const armpl_int_t *ldaf,
                     double *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA,N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1,N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF,N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by ZPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1,N).

WORK Input parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *cla_porpvgrw*, *dla_porpvgrw* and *sla_porpvgrw*.

4.17.671 zla_syamv

ZLA_SYAMV performs the matrix-vector operation

```
y := alpha*abs(A)*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an n by n symmetric matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_syamv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void zla_syamv_(const armpl_int_t *uplo, const armpl_int_t *n,
                const double *alpha, const armpl_doublecomplex_t *a,
                const armpl_int_t *lda, const armpl_doublecomplex_t *x,
                const armpl_int_t *incx, const double *beta, double *y,
                const armpl_int_t *incy);
```

Parameters

UPLO Input parameter.

UPLO is INTEGER

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = BLAS_UPPER Only the upper triangular part of A is to be referenced.

UPLO = BLAS_LOWER Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION .

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, n).. Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n). Unchanged on exit.

X Input parameter.

X is COMPLEX*16

X is an array, dimension at least. (1 + (n - 1)*abs(INCX)) Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is DOUBLE PRECISION .

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is DOUBLE PRECISION

Y is an array, dimension. (1 + (n - 1)*abs(INCY)) Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

4.17.672 zla_syrcond_c

```
ZLA_SYRCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector.
```

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_syrcond_c(UPLO, N, A, LDA, AF, LDAF, IPIV, C,
                                        CAPPLY, INFO, WORK, RWORK)
```

C specification:

```
#include "armpl.h"

double zla_syrcond_c_(const char *uplo, const armpl_int_t *n,
                      const armpl_doublecomplex_t *a, const armpl_int_t *lda,
```

                        const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                        const double *c, const armpl_int_t *capply,
                        armpl_int_t *info, const armpl_doublecomplex_t *work,
                        const double *rwork, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N).. Workspace.

4.17.674 zla_syrfsx_extended

zla_syrfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by ZSYRFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_syrfsx_extended(PREC_TYPE, UPLO, N, NRHS, A, LDA, AF, LDAF,
                               IPIV, COLEQU, C, B, LDB, Y, LDY, BERR_OUT,
                               N_NORMS, ERR_BNDS_NORM, ERR_BNDS_COMP, RES,
                               AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
                               DZ_UB, IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void zla_syrfsx_extended_(const armpl_int_t *prec_type, const char *uplo,
                          const armpl_int_t *n, const armpl_int_t *nrhs,
                          const armpl_doublecomplex_t *a,
                          const armpl_int_t *lda,
                          const armpl_doublecomplex_t *af,
                          const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const double *c,
                          const armpl_doublecomplex_t *b,
                          const armpl_int_t *ldb, armpl_doublecomplex_t *y,
                          const armpl_int_t *ldy, double *berr_out,
                          const armpl_int_t *n_norms, double *err_bnds_norm,
                          double *err_bnds_comp, armpl_doublecomplex_t *res,
                          double *ayb, armpl_doublecomplex_t *dy,
                          armpl_doublecomplex_t *y_tail, const double *rcond,
                          const armpl_int_t *ithresh, const double *rthresh,
                          const double *dz_ub,
                          const armpl_int_t *ignore_cwise, armpl_int_t *info,
                          ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by ZSYTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is DOUBLE PRECISION

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by ZLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is DOUBLE PRECISION

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is DOUBLE PRECISION

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix

Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX*16

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is DOUBLE PRECISION

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX*16

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX*16

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is DOUBLE PRECISION

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is DOUBLE PRECISION

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is DOUBLE PRECISION

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to ZLA_HERFSX_EXTENDED had an illegal value

Related Information

For this routine in other precisions, please see *cla_syrfsx_extended*, *dla_syrfsx_extended* and *sla_syrfsx_extended*.

4.17.675 zla_syrpvgrw

ZLA_SYRPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

double precision function zla_syrpvgrw(UPLO, N, INFO, A, LDA, AF, LDAF, IPIV,
                                       WORK)
```

C specification:

```
#include "armpl.h"

double zla_syrpvgrw_(const char *uplo, const armpl_int_t *n,
                     const armpl_int_t *info, const armpl_doublecomplex_t *a,
                     const armpl_int_t *lda, const armpl_doublecomplex_t *af,
                     const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                     double *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

INFO Input parameter.

INFO is INTEGER

The value of INFO returned from ZSYTRF, .i.e., the pivot in column INFO is exactly 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX*16

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

WORK Input parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *cla_syrpvgrw*, *dla_syrpvgrw* and *sla_syrpvgrw*.

4.17.676 zla_wwaddw

```
ZLA_WWADDW adds a vector W into a doubled-single vector (X, Y).

   This works for all extant IBM's hex and binary floating point
   arithmetics, but not for decimal.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zla_wwaddw(N, X, Y, W)
```

C specification:

```
#include "armpl.h"

void zla_wwaddw_(const armpl_int_t *n, armpl_doublecomplex_t *x,
                 armpl_doublecomplex_t *y, const armpl_doublecomplex_t *w);
```

Parameters

N Input parameter.

N is INTEGER

The length of vectors X, Y, and W.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (N). The first part of the doubled-single accumulation vector.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension (N). The second part of the doubled-single accumulation vector.

W Input parameter.

W is COMPLEX*16

W is an array, dimension (N). The vector to be added.

Related Information

For this routine in other precisions, please see *cla_wwaddw*, *dla_wwaddw* and *sla_wwaddw*.

4.17.677 zlabrd

zlabrd reduces the first NB rows and columns of a complex general m by n matrix A to upper or lower real bidiagonal form by a unitary transformation Q^H * A * P, and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A.

If m >= n, A is reduced to upper bidiagonal form; if m < n, to lower bidiagonal form.

This is an auxiliary routine called by ZGEBRD

Syntax

Fortran specification:

```
use armpl_library

subroutine zlabrd(M, N, NB, A, LDA, D, E, TAUQ, TAUP, X, LDX, Y, LDY)
```

C specification:

```
#include "armpl.h"

void zlabrd_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nb, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, double *d, double *e,
             armpl_doublecomplex_t *tauq, armpl_doublecomplex_t *taup,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx,
             armpl_doublecomplex_t *y, const armpl_int_t *ldy);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A.

N Input parameter.

N is INTEGER

The number of columns in the matrix A.

NB Input parameter.

NB is INTEGER

The number of leading rows and columns of A to be reduced.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the m by n general matrix to be reduced. On exit, the first NB rows and columns of the matrix are overwritten; the rest of the array is unchanged. If m >= n, elements on and below the diagonal in the first NB columns, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first NB rows, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. If m < n, elements below the diagonal in the first NB columns, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first NB rows, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (NB). The diagonal elements of the first NB rows and columns of the reduced matrix. D(i) = A(i,i).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (NB). The off-diagonal elements of the first NB rows and columns of the reduced matrix.

TAUQ Output parameter.

TAUQ is COMPLEX*16

TAUQ is an array, dimension (NB). The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP Output parameter.

TAUP is COMPLEX*16

TAUP is an array, dimension (NB). The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NB). The m-by-nb matrix X required to update the unreduced part of A.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, M).

Y Output parameter.

Y is COMPLEX*16

Y is an array, dimension (LDY, NB). The n-by-nb matrix Y required to update the unreduced part of A.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

Related Information

For this routine in other precisions, please see *clabrd*, *dlabrd* and *slabrd*.

4.17.678 zlacgv

zlacgv conjugates a complex vector of length N.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlacgv(N, X, INCX)
```

C specification:

```
#include "armpl.h"

void zlacgv_(const armpl_int_t *n, armpl_doublecomplex_t *x,
             const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vector X. N >= 0.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension. (1+(N-1)*abs(INCX)) On entry, the vector of length N to be conjugated. On exit, X is overwritten with conjg(X).

INCX Input parameter.

INCX is INTEGER

The spacing between successive elements of X.

Related Information

For this routine in other precisions, please see *clacgv*. It also exists with a native C interface as *LAPACKE_zlacgv*.

4.17.679 zlacn2

`zlacn2` estimates the 1-norm of a square, complex matrix A. Reverse communication is used for evaluating matrix-vector products.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlacn2(N, V, X, EST, KASE, ISAVE)
```

C specification:

```
#include "armpl.h"

void zlacn2_(const armpl_int_t *n, armpl_doublecomplex_t *v,
             armpl_doublecomplex_t *x, double *est, armpl_int_t *kase,
             armpl_int_t *isave);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 1.

V Output parameter.

V is COMPLEX*16

V is an array, dimension (N). On the final return, V = A*W, where EST = norm(V)/norm(W) (W is not returned).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (N). On an intermediate return, X should be overwritten by A * X, if KASE=1, A^H * X, if KASE=2, where A^H is the conjugate transpose of A, and ZLACN2 must be re-called with all the other parameters unchanged.

EST Input and output parameter.

EST is DOUBLE PRECISION

On entry with KASE = 1 or 2 and ISAVE(1) = 3, EST should be unchanged from the previous call to ZLACN2. On exit, EST is an estimate (a lower bound) for norm(A).

KASE Input and output parameter.

KASE is INTEGER

On the initial call to ZLACN2, KASE should be 0. On an intermediate return, KASE will be 1 or 2, indicating whether X should be overwritten by A * X or A^H * X. On the final return from ZLACN2, KASE will again be 0.

ISAVE Input and output parameter.

ISAVE is INTEGER array, dimension (3)

ISAVE is used to save variables between calls to ZLACN2

Related Information

For this routine in other precisions, please see *clacn2*, *dlacn2* and *slacn2*. It also exists with a native C interface as *LAPACKE_zlacn2*.

4.17.680 zlacon

`zlacon` estimates the 1-norm of a square, complex matrix A. Reverse communication is used for evaluating matrix-vector products.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlacon(N, V, X, EST, KASE)
```

C specification:

```
#include "armpl.h"

void zlacon_(const armpl_int_t *n, armpl_doublecomplex_t *v,
             armpl_doublecomplex_t *x, double *est, armpl_int_t *kase);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 1.

V Output parameter.

V is COMPLEX*16

V is an array, dimension (N). On the final return, V = A*W, where EST = norm(V)/norm(W) (W is not returned).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (N). On an intermediate return, X should be overwritten by A * X, if KASE=1, A^H * X, if KASE=2, where A^H is the conjugate transpose of A, and ZLACON must be re-called with all the other parameters unchanged.

EST Input and output parameter.

EST is DOUBLE PRECISION

On entry with KASE = 1 or 2 and JUMP = 3, EST should be unchanged from the previous call to ZLACON. On exit, EST is an estimate (a lower bound) for norm(A).

KASE Input and output parameter.

KASE is INTEGER

On the initial call to ZLACON, KASE should be 0. On an intermediate return, KASE will be 1 or 2, indicating whether X should be overwritten by A * X or A^H * X. On the final return from ZLACON, KASE will again be 0.

Related Information

For this routine in other precisions, please see *clacon*, *dlacon* and *slacon*.

4.17.681 zlacp2

`zlacp2` copies all or part of a real two-dimensional matrix A to a complex matrix B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlacp2(UPLO, M, N, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void zlacp2_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const double *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be copied to B. = 'U': Upper triangular part = 'L': Lower triangular part Otherwise: All of the matrix A

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The m by n matrix A. If UPLO = 'U', only the upper trapezium is accessed; if UPLO = 'L', only the lower trapezium is accessed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On exit, B = A in the locations specified by UPLO.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

Related Information

For this routine in other precisions, please see *clacp2*. It also exists with a native C interface as *LAPACKE_zlacp2*.

4.17.682 zlacpy

zlacpy copies all or part of a two-dimensional matrix A to another matrix B.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlacpy(UPLO, M, N, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void zlacpy_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be copied to B. = 'U': Upper triangular part = 'L': Lower triangular part Otherwise: All of the matrix A

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The m by n matrix A. If UPLO = 'U', only the upper trapezium is accessed; if UPLO = 'L', only the lower trapezium is accessed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On exit, B = A in the locations specified by UPLO.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

Related Information

For this routine in other precisions, please see *clacpy*, *dlacpy* and *slacpy*. It also exists with a native C interface as *LAPACKE_zlacpy*.

4.17.683 zlacrm

zlacrm performs a very simple matrix-matrix multiplication:

```
C := A * B,
```

where A is M by N and complex; B is N by N and real; C is M by N and complex.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlacrm(M, N, A, LDA, B, LDB, C, LDC, RWORK)
```

C specification:

```
#include "armpl.h"

void zlacrm_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const double *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *c, const armpl_int_t *ldc,
             double *rwork);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A and of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns and rows of the matrix B and the number of columns of the matrix C. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, A contains the M by N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >=max(1, M).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, B contains the N by N matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >=max(1, N).

C Output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On exit, C contains the M by N matrix C.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >=max(1, N).

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*M*N) .

Related Information

For this routine in other precisions, please see *clacrm*. It also exists with a native C interface as *LAPACKE_zlacrm*.

4.17.684 zlacrt

zlacrt performs the operation

```
(  c  s )( x )  ==> ( x )
( -s  c )( y )      ( y )
```

where c and s are complex and the vectors x and y are complex.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlacrt(N, CX, INCX, CY, INCY, C, S)
```

C specification:

```
#include "armpl.h"

void zlacrt_(const armpl_int_t *n, armpl_doublecomplex_t *cx,
             const armpl_int_t *incx, armpl_doublecomplex_t *cy,
             const armpl_int_t *incy, const armpl_doublecomplex_t *c,
             const armpl_doublecomplex_t *s);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements in the vectors CX and CY.

CX Input and output parameter.

CX is COMPLEX*16

CX is an array, dimension (N). On input, the vector x. On output, CX is overwritten with c*x + s*y.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of CX. INCX <> 0.

CY Input and output parameter.

CY is COMPLEX*16

CY is an array, dimension (N). On input, the vector y. On output, CY is overwritten with -s*x + c*y.

INCY Input parameter.

INCY is INTEGER

The increment between successive values of CY. INCY <> 0.

C Input parameter.

C is COMPLEX*16

S Input parameter.

S is COMPLEX*16

C and S define the matrix [C S]. [-S C]

Related Information

For this routine in other precisions, please see *clacrt*.

4.17.685 zladiv

zladiv := X / Y, where X and Y are complex. The computation of X / Y will not overflow on an intermediary step unless the results overflows.

Syntax

Fortran specification:

```
use armpl_library

complex*16 function zladiv(X, Y)
```

C specification:

```
#include "armpl.h"

DOUBLECOMPLEX_RET_VALUE zladiv_(DOUBLECOMPLEX_RET_PARAM const armpl_doublecomplex_
↪t *x,
                                const armpl_doublecomplex_t *y);
```

Parameters

X Input parameter.

X is COMPLEX*16

Y Input parameter.

Y is COMPLEX*16

The complex scalars X and Y.

Related Information

For this routine in other precisions, please see *cladiv*, *dladiv* and *sladiv*.

4.17.686 zlaed0

Using the divide and conquer method, zlaed0 computes all eigenvalues of a symmetric tridiagonal matrix which is one diagonal block of those from reducing a dense or band Hermitian matrix and corresponding eigenvectors of the dense or band matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaed0(QSIZ, N, D, E, Q, LDQ, QSTORE, LDQS, RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlaed0_(const armpl_int_t *qsiz, const armpl_int_t *n, double *d,
             double *e, armpl_doublecomplex_t *q, const armpl_int_t *ldq,
             armpl_doublecomplex_t *qstore, const armpl_int_t *ldqs,
             double *rwork, armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the unitary matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the diagonal elements of the tridiagonal matrix. On exit, the eigenvalues in ascending order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the off-diagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, Q must contain an QSIZ x N matrix whose columns unitarily orthonormal. It is a part of the unitary matrix that reduces the full dense Hermitian matrix to a (reducible) symmetric tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

IWORK Output parameter.

IWORK is INTEGER array,

the dimension of IWORK must be at least 6 + 6* N + 5*N*lg N (lg(N) = smallest integer k such that 2^k >= N)

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array,. dimension (1 + 3* N + 2*N*lg N + 3*N**2) (lg(N) = smallest integer k such that 2^k >= N)

QSTORE Output parameter.

QSTORE is COMPLEX*16

QSTORE is an array, dimension (LDQS, N). Used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

LDQS Input parameter.

LDQS is INTEGER

The leading dimension of the array QSTORE. LDQS >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *claed0*, *dlaed0* and *slaed0*.

4.17.687 zlaed7

zlaed7 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and optionally eigenvectors of a dense or banded Hermitian matrix that has been reduced to tridiagonal form.

```
T = Q(in) ( D(in) + RHO * Z*Z**H ) Q**H(in) = Q(out) * D(out) * Q**H(out)

where Z = Q**Hu, u is a vector of length N with ones in the
CUTPNT and CUTPNT + 1 th elements and zeros elsewhere.

 The eigenvectors of the original matrix are stored in Q, and the
 eigenvalues are in D.  The algorithm consists of three stages:

    The first stage consists of deflating the size of the problem
    when there are multiple eigenvalues or if there is a zero in
    the Z vector.  For each such occurrence the dimension of the
    secular equation problem is reduced by one.  This stage is
    performed by the routine DLAED2.

    The second stage consists of calculating the updated
    eigenvalues. This is done by finding the roots of the secular
    equation via the routine DLAED4 (as called by SLAED3).
    This routine also calculates the eigenvectors of the current
    problem.

    The final stage consists of computing the updated eigenvectors
    directly using the updated eigenvalues.  The eigenvectors for
    the current problem are multiplied with the eigenvectors from
    the overall problem.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaed7(N, CUTPNT, QSIZ, TLVLS, CURLVL, CURPBM, D, Q, LDQ, RHO,
                  INDXQ, QSTORE, QPTR, PRMPTR, PERM, GIVPTR, GIVCOL, GIVNUM,
                  WORK, RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlaed7_(const armpl_int_t *n, const armpl_int_t *cutpnt,
             const armpl_int_t *qsiz, const armpl_int_t *tlvls,
             const armpl_int_t *curlvl, const armpl_int_t *curpbm, double *d,
             armpl_doublecomplex_t *q, const armpl_int_t *ldq,
             const double *rho, armpl_int_t *indxq, double *qstore,
             armpl_int_t *qptr, const armpl_int_t *prmptr,
             const armpl_int_t *perm, const armpl_int_t *givptr,
             const armpl_int_t *givcol, const double *givnum,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

CUTPNT Input parameter.

CUTPNT is INTEGER

Contains the location of the last eigenvalue in the leading sub-matrix. min(1, N) <= CUTPNT <= N.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the unitary matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N.

TLVLS Input parameter.

TLVLS is INTEGER

The total number of merging levels in the overall divide and conquer tree.

CURLVL Input parameter.

CURLVL is INTEGER

The current level in the overall merge routine, 0 <= curlvl <= tlvls.

CURPBM Input parameter.

CURPBM is INTEGER

The current problem in the current level in the overall merge routine (counting from upper left to lower right).

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the eigenvalues of the rank-1-perturbed matrix. On exit, the eigenvalues of the repaired matrix.

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, the eigenvectors of the rank-1-perturbed matrix. On exit, the eigenvectors of the repaired tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

RHO Input parameter.

RHO is DOUBLE PRECISION

Contains the subdiagonal element used to create the rank-1 modification.

INDXQ Output parameter.

INDXQ is INTEGER array, dimension (N)

This contains the permutation which will reintegrate the subproblem just solved back into sorted order, ie. D(INDXQ(I = 1, N)) will be in ascending order.

IWORK Output parameter.

IWORK is INTEGER array, dimension (4*N)

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array,. dimension (3*N+2*QSIZ*N)

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (QSIZ*N) .

QSTORE Input and output parameter.

QSTORE is DOUBLE PRECISION

QSTORE is an array, dimension (N**2+1). Stores eigenvectors of submatrices encountered during divide and conquer, packed together. QPTR points to beginning of the submatrices.

QPTR Input and output parameter.

QPTR is INTEGER array, dimension (N+2)

List of indices pointing to beginning of submatrices stored in QSTORE. The submatrices are numbered starting at the bottom left of the divide and conquer tree, from left to right and bottom to top.

PRMPTR Input parameter.

PRMPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in PERM a level's permutation is stored. PRMPTR(i+1) - PRMPTR(i) indicates the size of the permutation and also the size of the full, non-deflated problem.

PERM Input parameter.

PERM is INTEGER array, dimension (N lg N)

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in GIVCOL a level's Givens rotations are stored. GIVPTR(i+1) - GIVPTR(i) indicates the number of Givens rotations.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (2, N lg N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Input parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (2, N lg N). Each number indicates the S value to be used in the corresponding Givens rotation.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *claed7*, *dlaed7* and *slaed7*.

4.17.688 zlaed8

zlaed8 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny element in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaed8(K, N, QSIZ, Q, LDQ, D, RHO, CUTPNT, Z, DLAMDA, Q2, LDQ2, W,
                  INDXP, INDX, INDXQ, PERM, GIVPTR, GIVCOL, GIVNUM, INFO)
```

C specification:

```
#include "armpl.h"

void zlaed8_(armpl_int_t *k, const armpl_int_t *n, const armpl_int_t *qsiz,
             armpl_doublecomplex_t *q, const armpl_int_t *ldq, double *d,
             double *rho, const armpl_int_t *cutpnt, const double *z,
             double *dlamda, armpl_doublecomplex_t *q2,
             const armpl_int_t *ldq2, double *w, armpl_int_t *indxp,
             armpl_int_t *indx, const armpl_int_t *indxq, armpl_int_t *perm,
             armpl_int_t *givptr, armpl_int_t *givcol, double *givnum,
             armpl_int_t *info);
```

Parameters

K Output parameter.

K is INTEGER

Contains the number of non-deflated eigenvalues. This is the order of the related secular equation.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the unitary matrix used to reduce the dense or band matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, Q contains the eigenvectors of the partially solved system which has been previously updated in matrix multiplies with other partially solved eigensystems. On exit, Q contains the trailing (N-K) updated eigenvectors (those which were deflated) in its last N-K columns.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, D contains the eigenvalues of the two submatrices to be combined. On exit, D contains the trailing (N-K) updated eigenvalues (those which were deflated) sorted into increasing order.

RHO Input and output parameter.

RHO is DOUBLE PRECISION

Contains the off diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined. RHO is modified during the computation to the value required by DLAED3.

CUTPNT Input parameter.

CUTPNT is INTEGER

Contains the location of the last eigenvalue in the leading sub-matrix. MIN(1, N) <= CUTPNT <= N.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (N). On input this vector contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). The contents of Z are destroyed during the updating process.

DLAMDA Output parameter.

DLAMDA is DOUBLE PRECISION

DLAMDA is an array, dimension (N). Contains a copy of the first K eigenvalues which will be used by DLAED3 to form the secular equation.

Q2 Output parameter.

Q2 is COMPLEX*16

Q2 is an array, dimension (LDQ2, N). If ICOMPQ = 0, Q2 is not referenced. Otherwise, Contains a copy of the first K eigenvectors which will be used by DLAED7 in a matrix multiply (DGEMM) to update the new eigenvectors.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of the array Q2. LDQ2 >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). This will hold the first k values of the final deflation-altered z-vector and will be passed to DLAED3.

INDXP Output parameter.

INDXP is INTEGER array, dimension (N)

This will contain the permutation used to place deflated values of D at the end of the array. On output INDXP(1:K) points to the nondeflated D-values and INDXP(K+1:N) points to the deflated eigenvalues.

INDX Output parameter.

INDX is INTEGER array, dimension (N)

This will contain the permutation used to sort the contents of D into ascending order.

INDXQ Input parameter.

INDXQ is INTEGER array, dimension (N)

This contains the permutation which separately sorts the two sub-problems in D into ascending order. Note that elements in the second half of this permutation must first have CUTPNT added to their values in order to be accurate.

PERM Output parameter.

PERM is INTEGER array, dimension (N)

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Output parameter.

GIVPTR is INTEGER

Contains the number of Givens rotations which took place in this subproblem.

GIVCOL Output parameter.

GIVCOL is INTEGER array, dimension (2, N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Output parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (2, N). Each number indicates the S value to be used in the corresponding Givens rotation.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *claed8*, *dlaed8* and *slaed8*.

4.17.689 zlaein

zlaein uses inverse iteration to find a right or left eigenvector corresponding to the eigenvalue W of a complex upper Hessenberg matrix H.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaein(RIGHTV, NOINIT, N, H, LDH, W, V, B, LDB, RWORK, EPS3,
                  SMLNUM, INFO)
```

C specification:

```
#include "armpl.h"

void zlaein_(const armpl_int_t *rightv, const armpl_int_t *noinit,
             const armpl_int_t *n, const armpl_doublecomplex_t *h,
             const armpl_int_t *ldh, const armpl_doublecomplex_t *w,
             armpl_doublecomplex_t *v, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, double *rwork, const double *eps3,
             const double *smlnum, armpl_int_t *info);
```

Parameters

RIGHTV Input parameter.

RIGHTV is LOGICAL

= .TRUE. : compute right eigenvector; = .FALSE.: compute left eigenvector.

NOINIT Input parameter.

NOINIT is LOGICAL

= .TRUE. : no initial vector supplied in V = .FALSE.: initial vector supplied in V.

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

H Input parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). The upper Hessenberg matrix H.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

W Input parameter.

W is COMPLEX*16

The eigenvalue of H whose corresponding right or left eigenvector is to be computed.

V Input and output parameter.

V is COMPLEX*16

V is an array, dimension (N). On entry, if NOINIT = .FALSE., V must contain a starting vector for inverse iteration; otherwise V need not be set. On exit, V contains the computed eigenvector, normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x| + |y|.

B Output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N) .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

EPS3 Input parameter.

EPS3 is DOUBLE PRECISION

A small machine-dependent value which is used to perturb close eigenvalues, and to replace zero pivots.

SMLNUM Input parameter.

SMLNUM is DOUBLE PRECISION

A machine-dependent value close to the underflow threshold.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit = 1: inverse iteration did not converge; V is set to the last iterate.

Related Information

For this routine in other precisions, please see *claein*, *dlaein* and *slaein*.

4.17.690 zlaesy

`zlaesy` computes the eigendecomposition of a 2-by-2 symmetric matrix

```
( ( A, B );( B, C ) )
```

provided the norm of the matrix of eigenvectors is larger than some threshold value.

RT1 is the eigenvalue of larger absolute value, and RT2 of smaller absolute value. If the eigenvectors are computed, then on return (CS1, SN1) is the unit eigenvector for RT1, hence

[CS1 SN1] . [A B] . [CS1 -SN1] = [RT1 0] [-SN1 CS1] [B C] [SN1 CS1] [0 RT2]

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaesy(A, B, C, RT1, RT2, EVSCAL, CS1, SN1)
```

C specification:

```
#include "armpl.h"

void zlaesy_(const armpl_doublecomplex_t *a, const armpl_doublecomplex_t *b,
             const armpl_doublecomplex_t *c, armpl_doublecomplex_t *rt1,
             armpl_doublecomplex_t *rt2, armpl_doublecomplex_t *evscal,
             armpl_doublecomplex_t *cs1, armpl_doublecomplex_t *sn1);
```

Parameters

A Input parameter.

`A` is `COMPLEX*16`

The (1, 1) element of input matrix.

B Input parameter.

`B` is `COMPLEX*16`

The (1, 2) element of input matrix. The (2, 1) element is also given by `B`, since the 2-by-2 matrix is symmetric.

C Input parameter.

`C` is `COMPLEX*16`

The (2, 2) element of input matrix.

RT1 Output parameter.

`RT1` is `COMPLEX*16`

The eigenvalue of larger modulus.

RT2 Output parameter.

RT2 is COMPLEX*16

The eigenvalue of smaller modulus.

EVSCAL Output parameter.

EVSCAL is COMPLEX*16

The complex value by which the eigenvector matrix was scaled to make it orthonormal. If EVSCAL is zero, the eigenvectors were not computed. This means one of two things: the 2-by-2 matrix could not be diagonalized, or the norm of the matrix of eigenvectors before scaling was larger than the threshold value THRESH (set below).

CS1 Output parameter.

CS1 is COMPLEX*16

SN1 Output parameter.

SN1 is COMPLEX*16

If EVSCAL .NE. 0, (CS1, SN1) is the unit right eigenvector for RT1.

Related Information

For this routine in other precisions, please see *claesy*.

4.17.691 zlaev2

zlaev2 computes the eigendecomposition of a 2-by-2 Hermitian matrix

```
[  A         B  ]
[  CONJG(B)  C  ].
```

On return, RT1 is the eigenvalue of larger absolute value, RT2 is the eigenvalue of smaller absolute value, and (CS1,SN1) is the unit right eigenvector for RT1, giving the decomposition

[CS1 CONJG(SN1)] [A B] [CS1 -CONJG(SN1)] = [RT1 0] [-SN1 CS1] [CONJG(B) C] [SN1 CS1] [0 RT2].

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaev2(A, B, C, RT1, RT2, CS1, SN1)
```

C specification:

```
#include "armpl.h"

void zlaev2_(const armpl_doublecomplex_t *a, const armpl_doublecomplex_t *b,
             const armpl_doublecomplex_t *c, double *rt1, double *rt2,
             double *cs1, armpl_doublecomplex_t *sn1);
```

Parameters

A Input parameter.

A is COMPLEX*16

The (1,1) element of the 2-by-2 matrix.

B Input parameter.

B is COMPLEX*16

The (1,2) element and the conjugate of the (2,1) element of the 2-by-2 matrix.

C Input parameter.

C is COMPLEX*16

The (2,2) element of the 2-by-2 matrix.

RT1 Output parameter.

RT1 is DOUBLE PRECISION

The eigenvalue of larger absolute value.

RT2 Output parameter.

RT2 is DOUBLE PRECISION

The eigenvalue of smaller absolute value.

CS1 Output parameter.

CS1 is DOUBLE PRECISION

SN1 Output parameter.

SN1 is COMPLEX*16

The vector (CS1, SN1) is a unit right eigenvector for RT1.

Related Information

For this routine in other precisions, please see *claev2*, *dlaev2* and *slaev2*.

4.17.692 zlag2c

zlag2c converts a COMPLEX*16 matrix, SA, to a COMPLEX matrix, A.

RMAX is the overflow for the SINGLE PRECISION arithmetic zlag2c checks that all the entries of A are between -RMAX and RMAX. If not the conversion is aborted and a flag is raised.

This is an auxiliary routine so there is no argument checking.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlag2c(M, N, A, LDA, SA, LDSA, INFO)
```

C specification:

```
#include "armpl.h"

void zlag2c_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *sa, const armpl_int_t *ldsa,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of lines of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N coefficient matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

SA Output parameter.

SA is COMPLEX

SA is an array, dimension (LDSA, N). On exit, if INFO=0, the M-by-N coefficient matrix SA; if INFO>0, the content of SA is unspecified.

LDSA Input parameter.

LDSA is INTEGER

The leading dimension of the array SA. LDSA >= max(1, M).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. = 1: an entry of the matrix A is greater than the SINGLE PRECISION overflow threshold, in this case, the content of SA in exit is unspecified.

Related Information

It also exists with a native C interface as *LAPACKE_zlag2c*.

4.17.693 zlags2

zlags2 computes 2-by-2 unitary matrices U, V and Q, such that if (UPPER) then

```
U**H *A*Q = U**H *( A1 A2 )*Q = ( x  0  )
                  ( 0  A3 )     ( x  x  )
```

and

```
V**H*B*Q = V**H *( B1  B2 )*Q = ( x   0  )
                ( 0   B3 )      ( x   x  )
```

or if (.NOT.UPPER) then

```
U**H *A*Q = U**H *( A1  0  )*Q = ( x   x  )
                 ( A2  A3 )      ( 0   x  )
```

and

```
V**H *B*Q = V**H *( B1  0  )*Q = ( x   x  )
                 ( B2  B3 )      ( 0   x  )
```

where

```
 U = (    CSU     SNU ), V = (  CSV     SNV ),
     ( -SNU**H   CSU )       ( -SNV**H CSV )

Q = (    CSQ     SNQ )
     ( -SNQ**H   CSQ )
```

The rows of the transformed A and B are parallel. Moreover, if the input 2-by-2 matrix A is not zero, then the transformed (1,1) entry of A is not zero. If the input matrices A and B are both not zero, then the transformed (2,2) element of B is not zero, except when the first rows of input A and B are parallel and the second rows are zero.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlags2(UPPER, A1, A2, A3, B1, B2, B3, CSU, SNU, CSV, SNV, CSQ,
                  SNQ)
```

C specification:

```
#include "armpl.h"

void zlags2_(const armpl_int_t *upper, const double *a1,
             const armpl_doublecomplex_t *a2, const double *a3,
             const double *b1, const armpl_doublecomplex_t *b2,
             const double *b3, double *csu, armpl_doublecomplex_t *snu,
             double *csv, armpl_doublecomplex_t *snv, double *csq,
             armpl_doublecomplex_t *snq);
```

Parameters

UPPER Input parameter.

UPPER is LOGICAL

= .TRUE.: the input matrices A and B are upper triangular. = .FALSE.: the input matrices A and B are lower triangular.

A1 Input parameter.

A1 is DOUBLE PRECISION

A2 Input parameter.

A2 is COMPLEX*16

A3 Input parameter.

A3 is DOUBLE PRECISION

On entry, A1, A2 and A3 are elements of the input 2-by-2 upper (lower) triangular matrix A.

B1 Input parameter.

B1 is DOUBLE PRECISION

B2 Input parameter.

B2 is COMPLEX*16

B3 Input parameter.

B3 is DOUBLE PRECISION

On entry, B1, B2 and B3 are elements of the input 2-by-2 upper (lower) triangular matrix B.

CSU Output parameter.

CSU is DOUBLE PRECISION

SNU Output parameter.

SNU is COMPLEX*16

The desired unitary matrix U.

CSV Output parameter.

CSV is DOUBLE PRECISION

SNV Output parameter.

SNV is COMPLEX*16

The desired unitary matrix V.

CSQ Output parameter.

CSQ is DOUBLE PRECISION

SNQ Output parameter.

SNQ is COMPLEX*16

The desired unitary matrix Q.

Related Information

For this routine in other precisions, please see *clags2*, *dlags2* and *slags2*.

4.17.694 zlagtm

zlagtm performs a matrix-vector product of the form

```
B := alpha * A * X + beta * B
```

where A is a tridiagonal matrix of order N, B and X are N by NRHS matrices, and alpha and beta are real scalars, each of which may be 0., 1., or -1.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlagtm(TRANS, N, NRHS, ALPHA, DL, D, DU, X, LDX, BETA, B, LDB)
```

C specification:

```
#include "armpl.h"

void zlagtm_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const double *alpha, const armpl_doublecomplex_t *dl,
             const armpl_doublecomplex_t *d, const armpl_doublecomplex_t *du,
             const armpl_doublecomplex_t *x, const armpl_int_t *ldx,
             const double *beta, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': No transpose, B := alpha * A * X + beta * B = 'T': Transpose, B := alpha * A^T * X + beta * B = 'C': Conjugate transpose, B := alpha * A^H * X + beta * B

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices X and B.

ALPHA Input parameter.

ALPHA is DOUBLE PRECISION

The scalar alpha. ALPHA must be 0., 1., or -1.; otherwise, it is assumed to be 0.

DL Input parameter.

DL is COMPLEX*16

DL is an array, dimension (N-1). The (n-1) sub-diagonal elements of T.

D Input parameter.

D is COMPLEX*16

D is an array, dimension (N). The diagonal elements of T.

DU Input parameter.

DU is COMPLEX*16

DU is an array, dimension (N-1). The (n-1) super-diagonal elements of T.

X Input parameter.

X is COMPLEX*16

X is an array, dimension (LDX, NRHS). The N by NRHS matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(N,1).

BETA Input parameter.

BETA is DOUBLE PRECISION

The scalar beta. BETA must be 0., 1., or -1.; otherwise, it is assumed to be 1.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the N by NRHS matrix B. On exit, B is overwritten by the matrix expression B := alpha * A * X + beta * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(N,1).

4.17.695 zlahef

zlahef computes a partial factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**H U22**H )
```

A = (L11 0) (D 0) ($L11^H$ $L21^H$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0      I     )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB. Note that U^H denotes the conjugate transpose of U.

zlahef is an auxiliary routine called by ZHETRF. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine zlahef(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void zlahef_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             armpl_int_t *kb, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv,
```

(continues on next page)

(continued from previous page)

```
            armpl_doublecomplex_t *w, const armpl_int_t *ldw,
            armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *clahef*.

4.17.696 zlahef_aa

DLAHEF_AA factorizes a panel of a complex hermitian matrix A using the Aasen's algorithm. The panel consists of a set of NB rows of A when UPLO is U, or a set of NB columns when UPLO is L.

In order to factorize the panel, the Aasen's algorithm requires the last row, or column, of the previous panel. The first row, or column, of A is set to be the first row, or column, of an identity matrix, which is used to factorize the first panel.

The resulting J-th row of U, or J-th column of L, is stored in the (J-1)-th row, or column, of A (without the unit diagonals), while the diagonal and subdiagonal of A are overwritten by those of T.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlahef_aa(UPLO, J1, M, NB, A, LDA, IPIV, H, LDH, WORK)
```

C specification:

```
#include "armpl.h"

void zlahef_aa_(const char *uplo, const armpl_int_t *j1, const armpl_int_t *m,
                const armpl_int_t *nb, armpl_doublecomplex_t *a,
                const armpl_int_t *lda, armpl_int_t *ipiv,
                armpl_doublecomplex_t *h, const armpl_int_t *ldh,
                armpl_doublecomplex_t *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

J1 Input parameter.

J1 is INTEGER

The location of the first row, or column, of the panel within the submatrix of A, passed to this routine, e.g., when called by ZHETRF_AA, for the first panel, J1 is 1, while for the remaining panels, J1 is 2.

M Input parameter.

M is INTEGER

The dimension of the submatrix. M >= 0.

NB Input parameter.

NB is INTEGER

The dimension of the panel to be facotorized.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, M) for. the first panel, while dimension (LDA,M+1) for the remaining panels.

On entry, A contains the last row, or column, of the previous panel, and the trailing submatrix of A to be factorized, except for the first panel, only the panel is passed.

On exit, the leading panel is factorized.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1,N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the row and column interchanges, the row and column k were interchanged with the row and column IPIV(k).

H Input and output parameter.

H is COMPLEX*16 workspace, dimension (LDH, NB).

LDH Input parameter.

LDH is INTEGER

The leading dimension of the workspace H. LDH >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16 workspace, dimension (M).

Related Information

For this routine in other precisions, please see *clahef_aa*.

4.17.697 zlahef_rook

ZLAHEF_ROOK computes a partial factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**H U22**H )
```

A = (L11 0) (D 0) ($L11^H$ $L21^H$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0      I     )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB. Note that U^H denotes the conjugate transpose of U.

ZLAHEF_ROOK is an auxiliary routine called by ZHETRF_ROOK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine zlahef_rook(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void zlahef_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nb, armpl_int_t *kb,
                  armpl_doublecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_doublecomplex_t *w,
                  const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *clahef_rook*.

4.17.698 zlahqr

```
ZLAHQR is an auxiliary routine called by CHSEQR to update the
   eigenvalues and Schur decomposition already computed by CHSEQR, by
   dealing with the Hessenberg submatrix in rows and columns ILO to
   IHI.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlahqr(WANTT, WANTZ, N, ILO, IHI, H, LDH, W, ILOZ, IHIZ, Z, LDZ,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zlahqr_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_doublecomplex_t *h,
             const armpl_int_t *ldh, armpl_doublecomplex_t *w,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns IHI+1:N, and that H(ILO,ILO-1) = 0 (unless ILO = 1). ZLAHQR works primarily with the Hessenberg submatrix in rows and columns ILO to IHI, but applies transformations to all of H if WANTT is .TRUE.. 1 <= ILO <= max(1, IHI); IHI <= N.

H Input and output parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO is zero and if WANTT is .TRUE., then H is upper triangular in rows and columns ILO:IHI. If INFO is zero and if WANTT is .FALSE., then the contents of H are unspecified on exit. The output state of H in case INF is positive is below under the description of INFO.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

W Output parameter.

W is COMPLEX*16

W is an array, dimension (N). The computed eigenvalues ILO to IHI are stored in the corresponding elements of W. If WANTT is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with W(i) = H(i,i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 <= ILOZ <= ILO; IHI <= IHIZ <= N.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If WANTZ is .TRUE., on entry Z must contain the current matrix Z of transformations accumulated by CHSEQR, and on exit Z has been updated; transformations are applied only to the submatrix Z(ILOZ:IHIZ,ILO:IHI). If WANTZ is .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: if INFO = i, ZLAHQR failed to compute all the eigenvalues ILO to IHI in a total of 30 iterations per eigenvalue; elements i+1:ihi of W contain those eigenvalues which have been successfully computed.

If INFO .GT. 0 and WANTT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO thorugh INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit (*) (initial value of H)*U = U*(final value of H) where U is an orthognal matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit (final value of Z) = (initial value of Z)*U where U is the orthogonal matrix in (*) (regardless of the value of WANTT.)

Related Information

For this routine in other precisions, please see *clahqr*, *dlahqr* and *slahqr*.

4.17.699 zlahr2

zlahr2 reduces the first NB columns of A complex general n-BY-(n-k+1) matrix A so that elements below the k-th subdiagonal are zero. The reduction is performed by an unitary similarity transformation Q^H * A * Q. The routine returns the matrices V and T which determine Q as a block reflector I - V*T*V^H , and also the matrix Y = A * V * T.

This is an auxiliary routine called by ZGEHRD.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlahr2(N, K, NB, A, LDA, TAU, T, LDT, Y, LDY)
```

C specification:

```
#include "armpl.h"

void zlahr2_(const armpl_int_t *n, const armpl_int_t *k,
             const armpl_int_t *nb, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *t, const armpl_int_t *ldt,
             armpl_doublecomplex_t *y, const armpl_int_t *ldy);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A.

K Input parameter.

K is INTEGER

The offset for the reduction. Elements below the k-th subdiagonal in the first NB columns are reduced to zero. K < N.

NB Input parameter.

NB is INTEGER

The number of columns to be reduced.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA,N-K+1). On entry, the n-by-(n-k+1) general matrix A. On exit, the elements on and above the k-th subdiagonal in the first NB columns are overwritten with the corresponding elements of the reduced matrix; the elements below the k-th subdiagonal, with the array TAU, represent the matrix Q as a product of elementary reflectors. The other columns of A are unchanged. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (NB). The scalar factors of the elementary reflectors. See Further Details.

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, NB). The upper triangular matrix T.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

Y Output parameter.

Y is COMPLEX*16

Y is an array, dimension (LDY, NB). The n-by-nb matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= N.

Related Information

For this routine in other precisions, please see *clahr2*, *dlahr2* and *slahr2*.

4.17.700 zlaic1

zlaic1 applies one step of incremental condition estimation in its simplest version:

Let x, twonorm(x) = 1, be an approximate singular vector of an j-by-j lower triangular matrix L, such that

```
twonorm(L*x) = sest
```

Then zlaic1 computes sestpr, s, c such that the vector

```
       [ s*x ]
xhat = [  c  ]
```

is an approximate singular vector of

```
       [ L       0   ]
Lhat = [ w**H gamma ]
```

in the sense that

```
twonorm(Lhat*xhat) = sestpr.
```

Depending on JOB, an estimate for the largest or smallest singular value is computed.

Note that [s c]^H and sestpr**2 is an eigenpair of the system

```
diag(sest*sest, 0) + [alpha  gamma] * [ conjg(alpha) ]
                                      [ conjg(gamma) ]
```

where alpha = x^H * w.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaic1(JOB, J, X, SEST, W, GAMMA, SESTPR, S, C)
```

C specification:

```
#include "armpl.h"

void zlaic1_(const armpl_int_t *job, const armpl_int_t *j,
             const armpl_doublecomplex_t *x, const double *sest,
             const armpl_doublecomplex_t *w,
             const armpl_doublecomplex_t *gamma, double *sestpr,
             armpl_doublecomplex_t *s, armpl_doublecomplex_t *c);
```

Parameters

JOB Input parameter.

JOB is INTEGER

= 1: an estimate for the largest singular value is computed. = 2: an estimate for the smallest singular value is computed.

J Input parameter.

J is INTEGER

Length of X and W

X Input parameter.

X is COMPLEX*16

X is an array, dimension (J). The j-vector x.

SEST Input parameter.

SEST is DOUBLE PRECISION

Estimated singular value of j by j matrix L

W Input parameter.

W is COMPLEX*16

W is an array, dimension (J). The j-vector w.

GAMMA Input parameter.

GAMMA is COMPLEX*16

The diagonal element gamma.

SESTPR Output parameter.

SESTPR is DOUBLE PRECISION

Estimated singular value of (j+1) by (j+1) matrix Lhat.

S Output parameter.

S is COMPLEX*16

Sine needed in forming xhat.

C Output parameter.

C is COMPLEX*16

Cosine needed in forming xhat.

Related Information

For this routine in other precisions, please see *claic1*, *dlaic1* and *slaic1*.

4.17.701 zlals0

zlals0 applies back the multiplying factors of either the left or the right singular vector matrix of a diagonal matrix appended by a row to the right hand side matrix B in solving the least squares problem using the divide-and-conquer SVD approach.

For the left singular vector matrix, three types of orthogonal matrices are involved:

(1L) Givens rotations: the number of such rotations is GIVPTR; the

```
pairs of columns/rows they were applied to are stored in GIVCOL;
and the C- and S-values of these rotations are stored in GIVNUM.
```

(2L) Permutation. The (NL+1)-st row of B is to be moved to the first

```
row, and for J=2:N, PERM(J)-th row of B is to be moved to the
J-th row.
```

(3L) The left singular vector matrix of the remaining matrix.

For the right singular vector matrix, four types of orthogonal matrices are involved:

(1R) The right singular vector matrix of the remaining matrix.

(2R) If SQRE = 1, one extra Givens rotation to generate the right

```
null space.
```

(3R) The inverse transformation of (2L).

(4R) The inverse transformation of (1L).

Syntax

Fortran specification:

```
use armpl_library

subroutine zlals0(ICOMPQ, NL, NR, SQRE, NRHS, B, LDB, BX, LDBX, PERM, GIVPTR,
                  GIVCOL, LDGCOL, GIVNUM, LDGNUM, POLES, DIFL, DIFR, Z, K, C,
                  S, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlals0_(const armpl_int_t *icompq, const armpl_int_t *nl,
             const armpl_int_t *nr, const armpl_int_t *sqre,
             const armpl_int_t *nrhs, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *bx,
             const armpl_int_t *ldbx, const armpl_int_t *perm,
             const armpl_int_t *givptr, const armpl_int_t *givcol,
             const armpl_int_t *ldgcol, const double *givnum,
             const armpl_int_t *ldgnum, const double *poles,
             const double *difl, const double *difr, const double *z,
             const armpl_int_t *k, const double *c, const double *s,
             double *rwork, armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in factored form: = 0: Left singular vector matrix. = 1: Right singular vector matrix.

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has row dimension N = NL + NR + 1, and column dimension M = N + SQRE.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B and BX. NRHS must be at least 1.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem in rows 1 through M. On output, B contains the solution X in rows 1 through N.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB must be at least max(1,MAX(M, N)).

BX Output parameter.

BX is COMPLEX*16

BX is an array, dimension (LDBX, NRHS) .

LDBX Input parameter.

LDBX is INTEGER

The leading dimension of BX.

PERM Input parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) applied to the two blocks.

GIVPTR Input parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2)

Each pair of numbers indicates a pair of rows/columns involved in a Givens rotation.

LDGCOL Input parameter.

LDGCOL is INTEGER

The leading dimension of GIVCOL, must be at least N.

GIVNUM Input parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (LDGNUM, 2). Each number indicates the C or S value used in the corresponding Givens rotation.

LDGNUM Input parameter.

LDGNUM is INTEGER

The leading dimension of arrays DIFR, POLES and GIVNUM, must be at least K.

POLES Input parameter.

POLES is DOUBLE PRECISION

POLES is an array, dimension (LDGNUM, 2). On entry, POLES(1:K, 1) contains the new singular values obtained from solving the secular equation, and POLES(1:K, 2) is an array containing the poles in the secular equation.

DIFL Input parameter.

DIFL is DOUBLE PRECISION

DIFL is an array, dimension (K).. On entry, DIFL(I) is the distance between I-th updated (undeflated) singular value and the I-th (undeflated) old singular value.

DIFR Input parameter.

DIFR is DOUBLE PRECISION

DIFR is an array, dimension (LDGNUM, 2).. On entry, DIFR(I, 1) contains the distances between I-th updated (undeflated) singular value and the I+1-th (undeflated) old singular value. And DIFR(I, 2) is the normalizing factor for the I-th right singular vector.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (K). Contain the components of the deflation-adjusted updating row vector.

K Input parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. 1 <= K <=N.

C Input parameter.

C is DOUBLE PRECISION

C contains garbage if SQRE =0 and the C-value of a Givens rotation related to the right null space if SQRE = 1.

S Input parameter.

S is DOUBLE PRECISION

S contains garbage if SQRE =0 and the S-value of a Givens rotation related to the right null space if SQRE = 1.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension. (K*(1+NRHS) + 2* NRHS)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

4.17.702 zlalsa

`zlalsa` is an itermediate step in solving the least squares problem by computing the SVD of the coefficient matrix in compact form (The singular vectors are computed as products of simple orthorgonal matrices.).

If ICOMPQ = 0, `zlalsa` applies the inverse of the left singular vector matrix of an upper bidiagonal matrix to the right hand side; and if ICOMPQ = 1, `zlalsa` applies the right singular vector matrix to the right hand side. The singular vector matrices were generated in compact form by `zlalsa`.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlalsa(ICOMPQ, SMLSIZ, N, NRHS, B, LDB, BX, LDBX, U, LDU, VT, K,
                  DIFL, DIFR, Z, POLES, GIVPTR, GIVCOL, LDGCOL, PERM, GIVNUM,
                  C, S, RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlalsa_(const armpl_int_t *icompq, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *bx, const armpl_int_t *ldbx,
             const double *u, const armpl_int_t *ldu, const double *vt,
             const armpl_int_t *k, const double *difl, const double *difr,
             const double *z, const double *poles, const armpl_int_t *givptr,
             const armpl_int_t *givcol, const armpl_int_t *ldgcol,
             const armpl_int_t *perm, const double *givnum, const double *c,
             const double *s, double *rwork, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

`ICOMPQ` is `INTEGER`

Specifies whether the left or the right singular vector matrix is involved. = 0: Left singular vector matrix = 1: Right singular vector matrix

SMLSIZ Input parameter.

`SMLSIZ` is `INTEGER`

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

`N` is `INTEGER`

The row and column dimensions of the upper bidiagonal matrix.

NRHS Input parameter.

`NRHS` is `INTEGER`

The number of columns of `B` and `BX`. `NRHS` must be at least 1.

B Input and output parameter.

`B` is `COMPLEX*16`

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem in rows 1 through M. On output, B contains the solution X in rows 1 through N.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B in the calling subprogram. LDB must be at least max(1,MAX(M, N)).

BX Output parameter.

BX is COMPLEX*16

BX is an array, dimension (LDBX, NRHS). On exit, the result of applying the left or right singular vector matrix to B.

LDBX Input parameter.

LDBX is INTEGER

The leading dimension of BX.

U Input parameter.

U is DOUBLE PRECISION

U is an array, dimension (LDU, SMLSIZ).. On entry, U contains the left singular vector matrices of all subproblems at the bottom level.

LDU Input parameter.

LDU is INTEGER, LDU = > N.

The leading dimension of arrays U, VT, DIFL, DIFR, POLES, GIVNUM, and Z.

VT Input parameter.

VT is DOUBLE PRECISION

VT is an array, dimension (LDU, SMLSIZ+1).. On entry, VT^H contains the right singular vector matrices of all subproblems at the bottom level.

K Input parameter.

K is INTEGER array, dimension (N).

DIFL Input parameter.

DIFL is DOUBLE PRECISION

DIFL is an array, dimension (LDU, NLVL).. where NLVL = INT(log_2 (N/(SMLSIZ+1))) + 1.

DIFR Input parameter.

DIFR is DOUBLE PRECISION

DIFR is an array, dimension (LDU, 2 * NLVL).. On entry, DIFL(*, I) and DIFR(*, 2 * I -1) record distances between singular values on the I-th level and singular values on the (I -1)-th level, and DIFR(*, 2 * I) record the normalizing factors of the right singular vectors matrices of subproblems on I-th level.

Z Input parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDU, NLVL).. On entry, Z(1, I) contains the components of the deflation- adjusted updating row vector for subproblems on the I-th level.

POLES Input parameter.

POLES is DOUBLE PRECISION

POLES is an array, dimension (LDU, 2 * NLVL).. On entry, POLES(*, 2 * I -1: 2 * I) contains the new and old singular values involved in the secular equations on the I-th level.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N).

On entry, GIVPTR(I) records the number of Givens rotations performed on the I-th problem on the computation tree.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2 * NLVL).

On entry, for each I, GIVCOL(*, 2 * I - 1: 2 * I) records the locations of Givens rotations performed on the I-th level on the computation tree.

LDGCOL Input parameter.

LDGCOL is INTEGER, LDGCOL = > N.

The leading dimension of arrays GIVCOL and PERM.

PERM Input parameter.

PERM is INTEGER array, dimension (LDGCOL, NLVL).

On entry, PERM(*, I) records permutations done on the I-th level of the computation tree.

GIVNUM Input parameter.

GIVNUM is DOUBLE PRECISION

GIVNUM is an array, dimension (LDU, 2 * NLVL).. On entry, GIVNUM(*, 2 *I -1 : 2 * I) records the C- and S- values of Givens rotations performed on the I-th level on the computation tree.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N).. On entry, if the I-th subproblem is not square, C(I) contains the C-value of a Givens rotation related to the right null space of the I-th subproblem.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (N).. On entry, if the I-th subproblem is not square, S(I) contains the S-value of a Givens rotation related to the right null space of the I-th subproblem.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension at least. MAX((SMLSZ+1)*NRHS*3, N*(1+NRHS) + 2* NRHS).

IWORK Output parameter.

IWORK is INTEGER array, dimension (3*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *clalsa*, *dlalsa* and *slalsa*.

4.17.703 zlalsd

`zlalsd` uses the singular value decomposition of A to solve the least squares problem of finding X to minimize the Euclidean norm of each column of A*X-B, where A is N-by-N upper bidiagonal, and X and B are N-by-NRHS. The solution X overwrites B.

The singular values of A smaller than RCOND times the largest singular value are treated as zero in solving the least squares problem; in this case a minimum norm solution is returned. The actual singular values are returned in D in ascending order.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlalsd(UPLO, SMLSIZ, N, NRHS, D, E, B, LDB, RCOND, RANK, WORK,
                  RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlalsd_(const char *uplo, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *nrhs, double *d,
             double *e, armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             const double *rcond, armpl_int_t *rank,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': D and E define an upper bidiagonal matrix. = 'L': D and E define a lower bidiagonal matrix.

SMLSIZ Input parameter.

SMLSIZ is INTEGER

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

N is INTEGER

The dimension of the bidiagonal matrix. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B. NRHS must be at least 1.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry D contains the main diagonal of the bidiagonal matrix. On exit, if INFO = 0, D contains its singular values.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). Contains the super-diagonal entries of the bidiagonal matrix. On exit, E has been destroyed.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem. On output, B contains the solution X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B in the calling subprogram. LDB must be at least max(1, N).

RCOND Input parameter.

RCOND is DOUBLE PRECISION

The singular values of A less than or equal to RCOND times the largest singular value are treated as zero in solving the least squares problem. If RCOND is negative, machine precision is used instead. For example, if diag(S)*X=B were the least squares problem, where diag(S) is a diagonal matrix of singular values, the solution would be X(i) = B(i) / S(i) if S(i) is greater than RCOND*max(S), and X(i) = 0 if S(i) is less than or equal to RCOND*max(S).

RANK Output parameter.

RANK is INTEGER

The number of singular values of A greater than RCOND times the largest singular value.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N * NRHS) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension at least. (9* N + 2*N* SMLSIZ + 8*N*NLVL + 3*SMLSIZ* NRHS + MAX((SMLSIZ+1)**2, N*(1+NRHS) + 2* NRHS), where NLVL = MAX(0, INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1)

IWORK Output parameter.

IWORK is INTEGER array, dimension at least

(3*N*NLVL + 11*N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute a singular value while working on the submatrix lying in rows and columns INFO/(N+1) through MOD(INFO,N+1).

Related Information

For this routine in other precisions, please see *clalsd*, *dlalsd* and *slalsd*.

4.17.704 zlamswlq

ZLAMQRTS overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by short wide LQ factorization (ZLASWLQ)

Syntax

Fortran specification:

```
use armpl_library

subroutine zlamswlq(SIDE, TRANS, M, N, K, MB, NB, A, LDA, T, LDT, C, LDC,
                    WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlamswlq_(const char *side, const char *trans, const armpl_int_t *m,
               const armpl_int_t *n, const armpl_int_t *k,
               const armpl_int_t *mb, const armpl_int_t *nb,
               armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_doublecomplex_t *t, const armpl_int_t *ldt,
               armpl_doublecomplex_t *c, const armpl_int_t *ldc,
               armpl_doublecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0;

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. M >= MB >= 1

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. NB > M.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. MB > M.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the blocked elementary reflector H(i), for i = 1,2,...,k, as returned by ZLASWLQ in the first k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is COMPLEX*16

T is an array, dimension. (M * Number of blocks(CEIL(N-K/NB-K)), The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) COMPLEX*16

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, NB) * MB; if SIDE = 'R', LWORK >= max(1, M) * MB. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clamswlq*, *dlamswlq* and *slamswlq*.

4.17.705 zlamtsqr

ZLAMTSQR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by tall skinny QR factorization (ZLATSQR)

Syntax

Fortran specification:

```
use armpl_library

subroutine zlamtsqr(SIDE, TRANS, M, N, K, MB, NB, A, LDA, T, LDT, C, LDC,
                    WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlamtsqr_(const char *side, const char *trans, const armpl_int_t *m,
               const armpl_int_t *n, const armpl_int_t *k,
               const armpl_int_t *mb, const armpl_int_t *nb,
               armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_doublecomplex_t *t, const armpl_int_t *ldt,
               armpl_doublecomplex_t *c, const armpl_int_t *ldc,
               armpl_doublecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0;

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. MB > N. (must be the same as DLATSQR)

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. N >= NB >= 1.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the blockedelementary reflector H(i), for i = 1,2,...,k, as returned by DLATSQR in the first k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is COMPLEX*16

T is an array, dimension. (N * Number of blocks(CEIL(M-K/MB-K)), The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) COMPLEX*16

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If SIDE = 'L', LWORK >= max(1, N)*NB; if SIDE = 'R', LWORK >= max(1, MB)*NB. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clamtsqr*, *dlamtsqr* and *slamtsqr*.

4.17.706 zlangb

`zlangb` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n band matrix A, with kl sub-diagonals and ku super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlangb(NORM, N, KL, KU, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

double zlangb_(const char *norm, const armpl_int_t *n, const armpl_int_t *kl,
               const armpl_int_t *ku, const armpl_doublecomplex_t *ab,
               const armpl_int_t *ldab, double *work, ... );
```

Returns

ZLANGB = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in ZLANGB as described above.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0. When `N` = 0, ZLANGB is set to zero.

KL Input parameter.

`KL` is `INTEGER`

The number of sub-diagonals of the matrix A. `KL` >= 0.

KU Input parameter.

`KU` is `INTEGER`

The number of super-diagonals of the matrix A. `KU` >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clangb*, *dlangb* and *slangb*.

4.17.707 zlange

zlange returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlange(NORM, M, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

double zlange_(const char *norm, const armpl_int_t *m, const armpl_int_t *n,
               const armpl_doublecomplex_t *a, const armpl_int_t *lda,
               double *work, ... );
```

Returns

ZLANGE = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANGE as described above.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0. When M = 0, ZLANGE is set to zero.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0. When N = 0, ZLANGE is set to zero.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The m by n matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clange*, *dlange* and *slange*. It also exists with a native C interface as *LAPACKE_zlange*.

4.17.708 zlangt

zlangt returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlangt(NORM, N, DL, D, DU)
```

C specification:

```
#include "armpl.h"

double zlangt_(const char *norm, const armpl_int_t *n,
               const armpl_doublecomplex_t *dl,
               const armpl_doublecomplex_t *d,
               const armpl_doublecomplex_t *du, ... );
```

Returns

ZLANGT = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANGT as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, ZLANGT is set to zero.

DL Input parameter.

DL is COMPLEX*16

DL is an array, dimension (N-1). The (n-1) sub-diagonal elements of A.

D Input parameter.

D is COMPLEX*16

D is an array, dimension (N). The diagonal elements of A.

DU Input parameter.

DU is COMPLEX*16

DU is an array, dimension (N-1). The (n-1) super-diagonal elements of A.

Related Information

For this routine in other precisions, please see *clangt*, *dlangt* and *slangt*.

4.17.709 zlanhb

zlanhb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n hermitian band matrix A, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlanhb(NORM, UPLO, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

double zlanhb_(const char *norm, const char *uplo, const armpl_int_t *n,
               const armpl_int_t *k, const armpl_doublecomplex_t *ab,
               const armpl_int_t *ldab, double *work, ... );
```

Returns

ZLANHB = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANHB as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the band matrix A is supplied. = ‘U’: Upper triangular = ‘L’: Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, ZLANHB is set to zero.

K Input parameter.

K is INTEGER

The number of super-diagonals or sub-diagonals of the band matrix A. K >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The upper or lower triangle of the hermitian band matrix A, stored in the first K+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = ‘U’, AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if UPLO = ‘L’, AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k). Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = ‘I’ or ‘1’ or ‘O’; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clanhb*.

4.17.710 zlanhe

`zlanhe` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex hermitian matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlanhe(NORM, UPLO, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

double zlanhe_(const char *norm, const char *uplo, const armpl_int_t *n,
               const armpl_doublecomplex_t *a, const armpl_int_t *lda,
               double *work, ... );
```

Returns

ZLANHE = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in ZLANHE as described above.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the upper or lower triangular part of the hermitian matrix `A` is to be referenced. = ‘`U`’: Upper triangular part of `A` is referenced = ‘`L`’: Lower triangular part of `A` is referenced

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0. When `N` = 0, ZLANHE is set to zero.

A Input parameter.

`A` is `COMPLEX*16`

`A` is an array, dimension (`LDA`, `N`). The hermitian matrix `A`. If `UPLO` = ‘`U`’, the leading n by n upper triangular part of `A` contains the upper triangular part of the matrix `A`, and the strictly lower triangular part of A is not

referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clanhe*. It also exists with a native C interface as *LAPACKE_zlanhe*.

4.17.711 zlanhf

zlanhf returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A in RFP format.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlanhf(NORM, TRANSR, UPLO, N, A, WORK)
```

C specification:

```
#include "armpl.h"

double zlanhf_(const char *norm, const char *transr, const char *uplo,
               const armpl_int_t *n, const armpl_doublecomplex_t *a,
               double *work, ... );
```

Returns

ZLANHF = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER

Specifies the value to be returned in ZLANHF as described above.

TRANSR Input parameter.

TRANSR is CHARACTER

Specifies whether the RFP format of A is normal or conjugate-transposed format. = 'N': RFP format is Normal = 'C': RFP format is Conjugate-transposed

UPLO Input parameter.

UPLO is CHARACTER

On entry, UPLO specifies whether the RFP matrix A came from an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' RFP A came from an upper triangular matrix

UPLO = 'L' or 'l' RFP A came from a lower triangular matrix

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, ZLANHF is set to zero.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (N*(N+1)/2);. On entry, the matrix A in RFP Format. RFP Format is described by TRANSR, UPLO and N as follows: If TRANSR='N' then RFP A is (0:N,0:K-1) when N is even; K=N/2. RFP A is (0:N-1,0:K) when N is odd; K=N/2. If TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the (N*(N+1)/2) elements of upper packed A either in normal or conjugate-transpose Format. If UPLO = 'L' the RFP A contains the (N*(N+1) /2) elements of lower packed A either in normal or conjugate-transpose Format. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and is N when is odd. See the Note below for more details. Unchanged on exit.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clanhf*.

4.17.712 zlanhp

zlanhp returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex hermitian matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlanhp(NORM, UPLO, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

double zlanhp_(const char *norm, const char *uplo, const armpl_int_t *n,
               const armpl_doublecomplex_t *ap, double *work, ... );
```

Returns

ZLANHP = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANHP as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the hermitian matrix A is supplied. = ‘U’: Upper triangular part of A is supplied = ‘L’: Lower triangular part of A is supplied

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, ZLANHP is set to zero.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = ‘U’, AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = ‘L’, AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = ‘I’ or ‘1’ or ‘O’; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clanhp*.

4.17.713 zlanhs

zlanhs returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hessenberg matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlanhs(NORM, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

double zlanhs_(const char *norm, const armpl_int_t *n,
               const armpl_doublecomplex_t *a, const armpl_int_t *lda,
               double *work, ... );
```

Returns

ZLANHS = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANHS as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, ZLANHS is set to zero.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The n by n upper Hessenberg matrix A; the part of A below the first sub-diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = ‘I’; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clanhs*, *dlanhs* and *slanhs*.

4.17.714 zlanht

`zlanht` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlanht(NORM, N, D, E)
```

C specification:

```
#include "armpl.h"

double zlanht_(const char *norm, const armpl_int_t *n, const double *d,
               const armpl_doublecomplex_t *e, ... );
```

Returns

ZLANHT = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in ZLANHT as described above.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0. When `N` = 0, ZLANHT is set to zero.

D Input parameter.

`D` is `DOUBLE PRECISION`

`D` is an array, dimension (`N`). The diagonal elements of A.

E Input parameter.

`E` is `COMPLEX*16`

`E` is an array, dimension (N-1). The (n-1) sub-diagonal or super-diagonal elements of A.

Related Information

For this routine in other precisions, please see *clanht*.

4.17.715 zlansb

`zlansb` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n symmetric band matrix A, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlansb(NORM, UPLO, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

double zlansb_(const char *norm, const char *uplo, const armpl_int_t *n,
               const armpl_int_t *k, const armpl_doublecomplex_t *ab,
               const armpl_int_t *ldab, double *work, ... );
```

Returns

ZLANSB = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in ZLANSB as described above.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the upper or lower triangular part of the band matrix A is supplied. = ‘`U`’: Upper triangular part is supplied = ‘`L`’: Lower triangular part is supplied

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0. When `N` = 0, ZLANSB is set to zero.

K Input parameter.

`K` is `INTEGER`

The number of super-diagonals or sub-diagonals of the band matrix A. `K` >= 0.

AB Input parameter.

`AB` is `COMPLEX*16`

`AB` is an array, dimension (`LDAB`, `N`). The upper or lower triangle of the symmetric band matrix A, stored in the first K+1 rows of `AB`. The j-th column of A is stored in the j-th column of the array `AB` as follows: if `UPLO` = ‘`U`’, AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if `UPLO` = ‘`L`’, AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clansb*, *dlansb* and *slansb*.

4.17.716 zlansp

zlansp returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex symmetric matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlansp(NORM, UPLO, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

double zlansp_(const char *norm, const char *uplo, const armpl_int_t *n,
               const armpl_doublecomplex_t *ap, double *work, ... );
```

Returns

ZLANSP = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANSP as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is supplied. = 'U': Upper triangular part of A is supplied = 'L': Lower triangular part of A is supplied

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, ZLANSP is set to zero.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clansp*, *dlansp* and *slansp*.

4.17.717 zlansy

zlansy returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex symmetric matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlansy(NORM, UPLO, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

double zlansy_(const char *norm, const char *uplo, const armpl_int_t *n,
               const armpl_doublecomplex_t *a, const armpl_int_t *lda,
               double *work, ... );
```

Returns

ZLANSY = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANSY as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced. = 'U': Upper triangular part of A is referenced = 'L': Lower triangular part of A is referenced

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, ZLANSY is set to zero.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clansy*, *dlansy* and *slansy*. It also exists with a native C interface as *LAPACKE_zlansy*.

4.17.718 zlantb

zlantb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n triangular band matrix A, with (k + 1) diagonals.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlantb(NORM, UPLO, DIAG, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

double zlantb_(const char *norm, const char *uplo, const char *diag,
               const armpl_int_t *n, const armpl_int_t *k,
               const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
               double *work, ... );
```

Returns

ZLANTB = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANTB as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, ZLANTB is set to zero.

K Input parameter.

K is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals of the matrix A if UPLO = 'L'. K >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first k+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k). Note that when DIAG = 'U', the elements of the array AB corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clantb*, *dlantb* and *slantb*.

4.17.719 zlantp

zlantp returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlantp(NORM, UPLO, DIAG, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

double zlantp_(const char *norm, const char *uplo, const char *diag,
               const armpl_int_t *n, const armpl_doublecomplex_t *ap,
               double *work, ... );
```

Returns

ZLANTP = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANTP as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, ZLANTP is set to zero.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. Note that when DIAG = 'U', the elements of the array AP corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clantp*, *dlantp* and *slantp*.

4.17.720 zlantr

zlantr returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix A.

Syntax

Fortran specification:

```
use armpl_library

double precision function zlantr(NORM, UPLO, DIAG, M, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

double zlantr_(const char *norm, const char *uplo, const char *diag,
               const armpl_int_t *m, const armpl_int_t *n,
               const armpl_doublecomplex_t *a, const armpl_int_t *lda,
               double *work, ... );
```

Returns

ZLANTR = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in ZLANTR as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower trapezoidal. = 'U': Upper trapezoidal = 'L': Lower trapezoidal Note that A is triangular instead of trapezoidal if M = N.

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A has unit diagonal. = 'N': Non-unit diagonal = 'U': Unit diagonal

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0, and if UPLO = 'U', M <= N. When M = 0, ZLANTR is set to zero.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0, and if UPLO = 'L', N <= M. When N = 0, ZLANTR is set to zero.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The trapezoidal matrix A (A is triangular if M = N). If UPLO = 'U', the leading m by n upper trapezoidal part of the array A contains the upper trapezoidal matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading m by n lower trapezoidal part of the array A contains the lower trapezoidal matrix, and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be one.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *clantr*, *dlantr* and *slantr*. It also exists with a native C interface as *LAPACKE_zlantr*.

4.17.721 zlapll

Given two column vectors X and Y, let

```
A = ( X Y ).
```

The subroutine first computes the QR factorization of A = Q*R, and then computes the SVD of the 2-by-2 upper triangular matrix R. The smaller singular value of R is returned in SSMIN, which is used as the measurement of the linear dependency of the vectors X and Y.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlapll(N, X, INCX, Y, INCY, SSMIN)
```

C specification:

```
#include "armpl.h"

void zlapll_(const armpl_int_t *n, armpl_doublecomplex_t *x,
             const armpl_int_t *incx, armpl_doublecomplex_t *y,
             const armpl_int_t *incy, double *ssmin);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors X and Y.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (1+(N-1)*INCX). On entry, X contains the N-vector X. On exit, X is overwritten.

INCX Input parameter.

INCX is INTEGER

The increment between successive elements of X. INCX > 0.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension (1+(N-1)*INCY). On entry, Y contains the N-vector Y. On exit, Y is overwritten.

INCY Input parameter.

INCY is INTEGER

The increment between successive elements of Y. INCY > 0.

SSMIN Output parameter.

SSMIN is DOUBLE PRECISION

The smallest singular value of the N-by-2 matrix A = (X Y).

Related Information

For this routine in other precisions, please see *clapll*, *dlapll* and *slapll*.

4.17.722 zlapmr

`zlapmr` rearranges the rows of the M by N matrix X as specified by the permutation K(1),K(2),...,K(M) of the integers 1,...,M. If FORWRD = .TRUE., forward permutation:

```
X(K(I),*) is moved X(I,*) for I = 1,2,...,M.
```

If FORWRD = .FALSE., backward permutation:

```
X(I,*) is moved to X(K(I),*) for I = 1,2,...,M.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlapmr(FORWRD, M, N, X, LDX, K)
```

C specification:

```
#include "armpl.h"

void zlapmr_(const armpl_int_t *forwrd, const armpl_int_t *m,
             const armpl_int_t *n, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, armpl_int_t *k);
```

Parameters

FORWRD Input parameter.

FORWRD is LOGICAL

= .TRUE., forward permutation = .FALSE., backward permutation

M Input parameter.

M is INTEGER

The number of rows of the matrix X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix X. N >= 0.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, N). On entry, the M by N matrix X. On exit, X contains the permuted matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X, LDX >= MAX(1, M).

K Input and output parameter.

K is INTEGER array, dimension (M)

On entry, K contains the permutation vector. K is used as internal workspace, but reset to its original value on output.

Related Information

For this routine in other precisions, please see *clapmr*, *dlapmr* and *slapmr*. It also exists with a native C interface as *LAPACKE_zlapmr*.

4.17.723 zlapmt

`zlapmt` rearranges the columns of the M by N matrix X as specified by the permutation K(1),K(2),...,K(N) of the integers 1,...,N. If FORWRD = .TRUE., forward permutation:

```
X(*,K(J)) is moved X(*,J) for J = 1,2,...,N.
```

If FORWRD = .FALSE., backward permutation:

```
X(*,J) is moved to X(*,K(J)) for J = 1,2,...,N.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlapmt(FORWRD, M, N, X, LDX, K)
```

C specification:

```
#include "armpl.h"

void zlapmt_(const armpl_int_t *forwrd, const armpl_int_t *m,
             const armpl_int_t *n, armpl_doublecomplex_t *x,
             const armpl_int_t *ldx, armpl_int_t *k);
```

Parameters

FORWRD Input parameter.

FORWRD is LOGICAL

= .TRUE., forward permutation = .FALSE., backward permutation

M Input parameter.

M is INTEGER

The number of rows of the matrix X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix X. N >= 0.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, N). On entry, the M by N matrix X. On exit, X contains the permuted matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X, LDX >= MAX(1, M).

K Input and output parameter.

K is INTEGER array, dimension (N)

On entry, K contains the permutation vector. K is used as internal workspace, but reset to its original value on output.

Related Information

For this routine in other precisions, please see *clapmt*, *dlapmt* and *slapmt*. It also exists with a native C interface as *LAPACKE_zlapmt*.

4.17.724 zlaqgb

zlaqgb equilibrates a general M by N band matrix A with KL subdiagonals and KU superdiagonals using the row and scaling factors in the vectors R and C.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqgb(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void zlaqgb_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             const double *r, const double *c, const double *rowcnd,
             const double *colcnd, const double *amax, char *equed, ... );
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, the equilibrated matrix, in the same storage format as A. See EQUED for the form of the equilibrated matrix.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDA >= KL+KU+1.

R Input parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). The row scale factors for A.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A.

ROWCND Input parameter.

ROWCND is DOUBLE PRECISION

Ratio of the smallest R(i) to the largest R(i).

COLCND Input parameter.

COLCND is DOUBLE PRECISION

Ratio of the smallest C(i) to the largest C(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C).

Related Information

For this routine in other precisions, please see *claqgb*, *dlaqgb* and *slaqgb*.

4.17.725 zlaqge

zlaqge equilibrates a general M by N matrix A using the row and column scaling factors in the vectors R and C.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqge(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void zlaqge_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const double *r, const double *c, const double *rowcnd,
             const double *colcnd, const double *amax, char *equed, ... );
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M by N matrix A. On exit, the equilibrated matrix. See EQUED for the form of the equilibrated matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

R Input parameter.

R is DOUBLE PRECISION

R is an array, dimension (M). The row scale factors for A.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (N). The column scale factors for A.

ROWCND Input parameter.

ROWCND is DOUBLE PRECISION

Ratio of the smallest R(i) to the largest R(i).

COLCND Input parameter.

COLCND is DOUBLE PRECISION

Ratio of the smallest C(i) to the largest C(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C).

Related Information

For this routine in other precisions, please see *claqge*, *dlaqge* and *slaqge*.

4.17.726 zlaqhb

zlaqhb equilibrates a Hermitian band matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqhb(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void zlaqhb_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab, double *s,
             const double *scond, const double *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is DOUBLE PRECISION

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqhb*.

4.17.727 zlaqhe

zlaqhe equilibrates a Hermitian matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqhe(UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void zlaqhe_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const double *s, const double *scond,
             const double *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if EQUED = 'Y', the equilibrated matrix: diag(S) * A * diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is DOUBLE PRECISION

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqhe*.

4.17.728 zlaqhp

zlaqhp equilibrates a Hermitian matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqhp(UPLO, N, AP, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void zlaqhp_(const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, const double *s, const double *scond,
             const double *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the equilibrated matrix: diag(S) * A * diag(S), in the same storage format as A.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is DOUBLE PRECISION

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqhp*.

4.17.729 zlaqp2

`zlaqp2` computes a QR factorization with column pivoting of the block A(OFFSET+1:M,1:N). The block A(1:OFFSET,1:N) is accordingly pivoted, but not factorized.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqp2(M, N, OFFSET, A, LDA, JPVT, TAU, VN1, VN2, WORK)
```

C specification:

```
#include "armpl.h"

void zlaqp2_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *offset, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *jpvt,
             armpl_doublecomplex_t *tau, double *vn1, double *vn2,
             armpl_doublecomplex_t *work);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

OFFSET Input parameter.

`OFFSET` is `INTEGER`

The number of rows of the matrix `A` that must be pivoted but no factorized. `OFFSET` >= 0.

A Input and output parameter.

`A` is `COMPLEX*16`

`A` is an array, dimension (`LDA`, `N`). On entry, the M-by-N matrix `A`. On exit, the upper triangle of block A(OFFSET+1:M,1:N) is the triangular factor obtained; the elements in block A(OFFSET+1:M,1:N) below the diagonal, together with the array `TAU`, represent the orthogonal matrix Q as a product of elementary reflectors. Block A(1:OFFSET,1:N) has been accordingly pivoted, but no factorized.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of A*P (a leading column); if JPVT(i) = 0, the i-th column of A is a free column. On exit, if JPVT(i) = k, then the i-th column of A*P was the k-th column of A.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors.

VN1 Input and output parameter.

VN1 is DOUBLE PRECISION

VN1 is an array, dimension (N). The vector with the partial column norms.

VN2 Input and output parameter.

VN2 is DOUBLE PRECISION

VN2 is an array, dimension (N). The vector with the exact column norms.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

Related Information

For this routine in other precisions, please see *claqp2*, *dlaqp2* and *slaqp2*.

4.17.730 zlaqps

zlaqps computes a step of QR factorization with column pivoting of a complex M-by-N matrix A by using Blas-3. It tries to factorize NB columns from A starting from the row OFFSET+1, and updates all of the matrix with Blas-3 xGEMM.

In some cases, due to catastrophic cancellations, it cannot factorize NB columns. Hence, the actual number of factorized columns is returned in KB.

Block A(1:OFFSET,1:N) is accordingly pivoted, but not factorized.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqps(M, N, OFFSET, NB, KB, A, LDA, JPVT, TAU, VN1, VN2, AUXV, F,
                  LDF)
```

C specification:

```
#include "armpl.h"

void zlaqps_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *offset, const armpl_int_t *nb,
             armpl_int_t *kb, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *jpvt,
```

(continues on next page)

(continued from previous page)

```
                armpl_doublecomplex_t *tau, double *vn1, double *vn2,
                armpl_doublecomplex_t *auxv, armpl_doublecomplex_t *f,
                const armpl_int_t *ldf);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0

OFFSET Input parameter.

OFFSET is INTEGER

The number of rows of A that have been factorized in previous steps.

NB Input parameter.

NB is INTEGER

The number of columns to factorize.

KB Output parameter.

KB is INTEGER

The number of columns actually factorized.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, block A(OFFSET+1:M,1:KB) is the triangular factor obtained and block A(1:OFFSET,1:N) has been accordingly pivoted, but no factorized. The rest of the matrix, block A(OFFSET+1:M,KB+1:N) has been updated.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

JPVT(I) = K <==> Column K of the full matrix A has been permuted into position I in AP.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (KB). The scalar factors of the elementary reflectors.

VN1 Input and output parameter.

VN1 is DOUBLE PRECISION

VN1 is an array, dimension (N). The vector with the partial column norms.

VN2 Input and output parameter.

VN2 is DOUBLE PRECISION

VN2 is an array, dimension (N). The vector with the exact column norms.

AUXV Input and output parameter.

AUXV is COMPLEX*16

AUXV is an array, dimension (NB). Auxiliar vector.

F Input and output parameter.

F is COMPLEX*16

F is an array, dimension (LDF, NB). Matrix $F^H = L * Y^H * A$.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the array F. LDF >= max(1, N).

4.17.731 zlaqr0

```
ZLAQR0 computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**H, where T is an upper triangular matrix (the
   Schur form), and Z is the unitary matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input unitary
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the unitary matrix Q:  A = Q*H*Q**H = (QZ)*H*(QZ)**H.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqr0(WANTT, WANTZ, N, ILO, IHI, H, LDH, W, ILOZ, IHIZ, Z, LDZ,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlaqr0_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_doublecomplex_t *h,
             const armpl_int_t *ldh, armpl_doublecomplex_t *w,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1, H(ILO,ILO-1) is zero. ILO and IHI are normally set by a previous call to ZGEBAL, and then passed to ZGEHRD when the matrix output by ZGEBAL is reduced to Hessenberg form. Otherwise, ILO and IHI should be set to 1 and N, respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and WANTT is .TRUE., then H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If INFO = 0 and WANT is .FALSE., then the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

This subroutine may explicitly set H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

W Output parameter.

W is COMPLEX*16

W is an array, dimension (N). The computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored in W(ILO:IHI). If WANTT is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with W(i) = H(i,i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, IHI). If WANTZ is .FALSE., then Z is not referenced. If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the orthogonal Schur factor of H(ILO:IHI,ILO:IHI). (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if WANTZ is .TRUE. then LDZ.GE.MAX(1, IHIZ). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension LWORK. On exit, if LWORK = -1, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient, but LWORK typically as large as 6* N may be required for optimal performance. A workspace query to determine the optimal workspace size is recommended.

If LWORK = -1, then ZLAQR0 does a workspace query. In this case, ZLAQR0 checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: if INFO = i, ZLAQR0 failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and WANT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is a unitary matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit

(final value of Z(ILO:IHI,ILOZ:IHIZ) = (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

where U is the unitary matrix in (*) (regard- less of the value of WANTT.)

If INFO .GT. 0 and WANTZ is .FALSE., then Z is not accessed.

Related Information

4.17.732 zlaqr1

```
Given a 2-by-2 or 3-by-3 matrix H, ZLAQR1 sets v to a
     scalar multiple of the first column of the product

     (*)  K = (H - s1*I)*(H - s2*I)

     scaling to avoid overflows and most underflows.

     This is useful for starting double implicit shift bulges
     in the QR algorithm.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqr1(N, H, LDH, S1, S2, V)
```

C specification:

```
#include "armpl.h"

void zlaqr1_(const armpl_int_t *n, const armpl_doublecomplex_t *h,
             const armpl_int_t *ldh, const armpl_doublecomplex_t *s1,
             const armpl_doublecomplex_t *s2, armpl_doublecomplex_t *v);
```

Parameters

N Input parameter.

N is INTEGER

Order of the matrix H. N must be either 2 or 3.

H Input parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). The 2-by-2 or 3-by-3 matrix H in (*).

LDH Input parameter.

LDH is INTEGER

The leading dimension of H as declared in the calling procedure. LDH.GE.N

S1 Input parameter.

S1 is COMPLEX*16

S2 Input parameter.

S2 is COMPLEX*16

S1 and S2 are the shifts defining K in (*) above.

V Output parameter.

V is COMPLEX*16

V is an array, dimension (N). A scalar multiple of the first column of the matrix K in (*).

Related Information

For this routine in other precisions, please see *claqr1*, *dlaqr1* and *slaqr1*.

4.17.733 zlaqr2

```
ZLAQR2 is identical to ZLAQR3 except that it avoids
   recursion by calling ZLAHQR instead of ZLAQR4.

   Aggressive early deflation:

   ZLAQR2 accepts as input an upper Hessenberg matrix
   H and performs an unitary similarity transformation
   designed to detect and deflate fully converged eigenvalues from
   a trailing principal submatrix.  On output H has been over-
   written by a new Hessenberg matrix that is a perturbation of
   an unitary similarity transformation of H.  It is to be
   hoped that the final version of H has many zero subdiagonal
   entries.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqr2(WANTT, WANTZ, N, KTOP, KBOT, NW, H, LDH, ILOZ, IHIZ, Z, LDZ,
                  NS, ND, SH, V, LDV, NH, T, LDT, NV, WV, LDWV, WORK, LWORK)
```

C specification:

```
#include "armpl.h"

void zlaqr2_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ktop,
             const armpl_int_t *kbot, const armpl_int_t *nw,
             armpl_doublecomplex_t *h, const armpl_int_t *ldh,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *ns, armpl_int_t *nd, armpl_doublecomplex_t *sh,
             armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             const armpl_int_t *nh, armpl_doublecomplex_t *t,
             const armpl_int_t *ldt, const armpl_int_t *nv,
             armpl_doublecomplex_t *wv, const armpl_int_t *ldwv,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

If .TRUE., then the Hessenberg matrix H is fully updated so that the triangular Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then only enough of H is updated to preserve the eigenvalues.

WANTZ Input parameter.

WANTZ is LOGICAL

If .TRUE., then the unitary matrix Z is updated so so that the unitary Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then Z is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix H and (if WANTZ is .TRUE.) the order of the unitary matrix Z.

KTOP Input parameter.

KTOP is INTEGER

It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

KBOT Input parameter.

KBOT is INTEGER

It is assumed without a check that either KBOT = N or H(KBOT+1, KBOT)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

NW Input parameter.

NW is INTEGER

Deflation window size. 1 .LE. NW .LE. (KBOT-KTOP+1).

H Input and output parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). On input the initial N-by-N section of H stores the Hessenberg matrix undergoing aggressive early deflation. On output H has been transformed by a unitary similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

LDH Input parameter.

LDH is INTEGER

Leading dimension of H just as declared in the calling subroutine. N .LE. LDH

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). IF WANTZ is .TRUE., then on output, the unitary similarity transformation mentioned above has been accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ is .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of Z just as declared in the calling subroutine. 1 .LE. LDZ.

NS Output parameter.

NS is INTEGER

The number of unconverged (ie approximate) eigenvalues returned in SR and SI that may be used as shifts by the calling subroutine.

ND Output parameter.

ND is INTEGER

The number of converged eigenvalues uncovered by this subroutine.

SH Output parameter.

SH is COMPLEX*16

SH is an array, dimension (KBOT). On output, approximate eigenvalues that may be used for shifts are stored in SH(KBOT-ND-NS+1) through SR(KBOT-ND). Converged eigenvalues are stored in SH(KBOT-ND+1) through SH(KBOT).

V Output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, NW). An NW-by-NW work array.

LDV Input parameter.

LDV is INTEGER

The leading dimension of V just as declared in the calling subroutine. NW .LE. LDV

NH Input parameter.

NH is INTEGER

The number of columns of T. NH.GE.NW.

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, NW) .

LDT Input parameter.

LDT is INTEGER

The leading dimension of T just as declared in the calling subroutine. NW .LE. LDT

NV Input parameter.

NV is INTEGER

The number of rows of work array WV available for workspace. NV.GE.NW.

WV Output parameter.

WV is COMPLEX*16

WV is an array, dimension (LDWV, NW) .

LDWV Input parameter.

LDWV is INTEGER

The leading dimension of W just as declared in the calling subroutine. NW .LE. LDV

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK). On exit, WORK(1) is set to an estimate of the optimal value of LWORK for the given values of N, NW, KTOP and KBOT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the work array WORK. LWORK = 2*NW suffices, but greater efficiency may result from larger values of LWORK.

If LWORK = -1, then a workspace query is assumed; ZLAQR2 only estimates the optimal workspace size for the given values of N, NW, KTOP and KBOT. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

Related Information

For this routine in other precisions, please see *claqr2*, *dlaqr2* and *slaqr2*.

4.17.734 zlaqr3

```
Aggressive early deflation:

   ZLAQR3 accepts as input an upper Hessenberg matrix
   H and performs an unitary similarity transformation
   designed to detect and deflate fully converged eigenvalues from
   a trailing principal submatrix.  On output H has been over-
   written by a new Hessenberg matrix that is a perturbation of
   an unitary similarity transformation of H.  It is to be
   hoped that the final version of H has many zero subdiagonal
   entries.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqr3(WANTT, WANTZ, N, KTOP, KBOT, NW, H, LDH, ILOZ, IHIZ, Z, LDZ,
                  NS, ND, SH, V, LDV, NH, T, LDT, NV, WV, LDWV, WORK, LWORK)
```

C specification:

```
#include "armpl.h"

void zlaqr3_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ktop,
             const armpl_int_t *kbot, const armpl_int_t *nw,
             armpl_doublecomplex_t *h, const armpl_int_t *ldh,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *ns, armpl_int_t *nd, armpl_doublecomplex_t *sh,
             armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             const armpl_int_t *nh, armpl_doublecomplex_t *t,
             const armpl_int_t *ldt, const armpl_int_t *nv,
             armpl_doublecomplex_t *wv, const armpl_int_t *ldwv,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

If .TRUE., then the Hessenberg matrix H is fully updated so that the triangular Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then only enough of H is updated to preserve the eigenvalues.

WANTZ Input parameter.

WANTZ is LOGICAL

If .TRUE., then the unitary matrix Z is updated so so that the unitary Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then Z is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix H and (if WANTZ is .TRUE.) the order of the unitary matrix Z.

KTOP Input parameter.

KTOP is INTEGER

It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

KBOT Input parameter.

KBOT is INTEGER

It is assumed without a check that either KBOT = N or H(KBOT+1, KBOT)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

NW Input parameter.

NW is INTEGER

Deflation window size. 1 .LE. NW .LE. (KBOT-KTOP+1).

H Input and output parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). On input the initial N-by-N section of H stores the Hessenberg matrix undergoing aggressive early deflation. On output H has been transformed by a unitary similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

LDH Input parameter.

LDH is INTEGER

Leading dimension of H just as declared in the calling subroutine. N .LE. LDH

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). IF WANTZ is .TRUE., then on output, the unitary similarity transformation mentioned above has been accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ is .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of Z just as declared in the calling subroutine. 1 .LE. LDZ.

NS Output parameter.

NS is INTEGER

The number of unconverged (ie approximate) eigenvalues returned in SR and SI that may be used as shifts by the calling subroutine.

ND Output parameter.

ND is INTEGER

The number of converged eigenvalues uncovered by this subroutine.

SH Output parameter.

SH is COMPLEX*16

SH is an array, dimension (KBOT). On output, approximate eigenvalues that may be used for shifts are stored in SH(KBOT-ND-NS+1) through SR(KBOT-ND). Converged eigenvalues are stored in SH(KBOT-ND+1) through SH(KBOT).

V Output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, NW). An NW-by-NW work array.

LDV Input parameter.

LDV is INTEGER

The leading dimension of V just as declared in the calling subroutine. NW .LE. LDV

NH Input parameter.

NH is INTEGER

The number of columns of T. NH.GE.NW.

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, NW) .

LDT Input parameter.

LDT is INTEGER

The leading dimension of T just as declared in the calling subroutine. NW .LE. LDT

NV Input parameter.

NV is INTEGER

The number of rows of work array WV available for workspace. NV.GE.NW.

WV Output parameter.

WV is COMPLEX*16

WV is an array, dimension (LDWV, NW) .

LDWV Input parameter.

LDWV is INTEGER

The leading dimension of W just as declared in the calling subroutine. NW .LE. LDV

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK). On exit, WORK(1) is set to an estimate of the optimal value of LWORK for the given values of N, NW, KTOP and KBOT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the work array WORK. LWORK = 2*NW suffices, but greater efficiency may result from larger values of LWORK.

If LWORK = -1, then a workspace query is assumed; ZLAQR3 only estimates the optimal workspace size for the given values of N, NW, KTOP and KBOT. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

4.17.735 zlaqr4

```
ZLAQR4 implements one level of recursion for ZLAQR0.
   It is a complete implementation of the small bulge multi-shift
   QR algorithm.  It may be called by ZLAQR0 and, for large enough
   deflation window size, it may be called by ZLAQR3.  This
   subroutine is identical to ZLAQR0 except that it calls ZLAQR2
   instead of ZLAQR3.

   ZLAQR4 computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**H, where T is an upper triangular matrix (the
   Schur form), and Z is the unitary matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input unitary
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the unitary matrix Q:  A = Q*H*Q**H = (QZ)*H*(QZ)**H.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqr4(WANTT, WANTZ, N, ILO, IHI, H, LDH, W, ILOZ, IHIZ, Z, LDZ,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlaqr4_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_doublecomplex_t *h,
             const armpl_int_t *ldh, armpl_doublecomplex_t *w,
             armpl_int_t *iloz, armpl_int_t *ihiz, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1, H(ILO,ILO-1) is zero. ILO and IHI are normally set by a previous call to ZGEBAL, and then passed to ZGEHRD when the matrix output by ZGEBAL is reduced to Hessenberg form. Otherwise, ILO and IHI should be set to 1 and N, respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and WANTT is .TRUE., then H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If INFO = 0 and WANT is .FALSE., then the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

This subroutine may explicitly set H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

W Output parameter.

W is COMPLEX*16

W is an array, dimension (N). The computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored in W(ILO:IHI). If WANTT is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with W(i) = H(i,i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, IHI). If WANTZ is .FALSE., then Z is not referenced. If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the orthogonal Schur factor

of H(ILO:IHI,ILO:IHI). (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if WANTZ is .TRUE. then LDZ.GE.MAX(1, IHIZ). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension LWORK. On exit, if LWORK = -1, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient, but LWORK typically as large as 6* N may be required for optimal performance. A workspace query to determine the optimal workspace size is recommended.

If LWORK = -1, then ZLAQR4 does a workspace query. In this case, ZLAQR4 checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: if INFO = i, ZLAQR4 failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and WANT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is a unitary matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit

(final value of Z(ILO:IHI,ILOZ:IHIZ) = (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

where U is the unitary matrix in (*) (regard- less of the value of WANTT.)

If INFO .GT. 0 and WANTZ is .FALSE., then Z is not accessed.

4.17.736 zlaqr5

```
ZLAQR5, called by ZLAQR0, performs a
   single small-bulge multi-shift QR sweep.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqr5(WANTT, WANTZ, KACC22, N, KTOP, KBOT, NSHFTS, S, H, LDH,
                  ILOZ, IHIZ, Z, LDZ, V, LDV, U, LDU, NV, WV, LDWV, NH, WH,
                  LDWH)
```

C specification:

```
#include "armpl.h"

void zlaqr5_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *kacc22, const armpl_int_t *n,
             const armpl_int_t *ktop, const armpl_int_t *kbot,
             const armpl_int_t *nshfts, armpl_doublecomplex_t *s,
             armpl_doublecomplex_t *h, const armpl_int_t *ldh,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             armpl_doublecomplex_t *u, const armpl_int_t *ldu,
             const armpl_int_t *nv, armpl_doublecomplex_t *wv,
             const armpl_int_t *ldwv, const armpl_int_t *nh,
             armpl_doublecomplex_t *wh, const armpl_int_t *ldwh);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

WANTT = .true. if the triangular Schur factor is being computed. WANTT is set to .false. otherwise.

WANTZ Input parameter.

WANTZ is LOGICAL

WANTZ = .true. if the unitary Schur factor is being computed. WANTZ is set to .false. otherwise.

KACC22 Input parameter.

KACC22 is INTEGER with value 0, 1, or 2.

Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: ZLAQR5 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: ZLAQR5 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: ZLAQR5 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.

N Input parameter.

N is INTEGER

N is the order of the Hessenberg matrix H upon which this subroutine operates.

KTOP Input parameter.

KTOP is INTEGER

KBOT Input parameter.

KBOT is INTEGER

These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either KTOP = 1 or H(KTOP,KTOP-1) = 0 and either KBOT = N or H(KBOT+1, KBOT) = 0.

NSHFTS Input parameter.

NSHFTS is INTEGER

NSHFTS gives the number of simultaneous shifts. NSHFTS must be positive and even.

S Input and output parameter.

S is COMPLEX*16

S is an array, dimension (NSHFTS). S contains the shifts of origin that define the multi- shift QR sweep. On output S may be reordered.

H Input and output parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). On input H contains a Hessenberg matrix. On output a multi-shift QR sweep with shifts SR(J)+i*SI(J) is applied to the isolated diagonal block in rows and columns KTOP through KBOT.

LDH Input parameter.

LDH is INTEGER

LDH is the leading dimension of H just as declared in the calling procedure. LDH.GE.MAX(1, N).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, IHIZ). If WANTZ = .TRUE., then the QR Sweep unitary similarity transformation is accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ = .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

LDA is the leading dimension of Z just as declared in the calling procedure. LDZ.GE.N.

V Output parameter.

V is COMPLEX*16

V is an array, dimension (LDV,NSHFTS/2) .

LDV Input parameter.

LDV is INTEGER

LDV is the leading dimension of V as declared in the calling procedure. LDV.GE.3.

U Output parameter.

U is COMPLEX*16

U is an array, dimension (LDU,3*NSHFTS-3) .

LDU Input parameter.

LDU is INTEGER

LDU is the leading dimension of U just as declared in the in the calling subroutine. LDU.GE.3*NSHFTS-3.

NH Input parameter.

NH is INTEGER

NH is the number of columns in array WH available for workspace. NH.GE.1.

WH Output parameter.

WH is COMPLEX*16

WH is an array, dimension (LDWH, NH) .

LDWH Input parameter.

LDWH is INTEGER

Leading dimension of WH just as declared in the calling procedure. LDWH.GE.3*NSHFTS-3.

NV Input parameter.

NV is INTEGER

NV is the number of rows in WV agailable for workspace. NV.GE.1.

WV Output parameter.

WV is COMPLEX*16

WV is an array, dimension (LDWV,3*NSHFTS-3) .

LDWV Input parameter.

LDWV is INTEGER

LDWV is the leading dimension of WV as declared in the in the calling subroutine. LDWV.GE.NV.

Related Information

For this routine in other precisions, please see *claqr5*, *dlaqr5* and *slaqr5*.

4.17.737 zlaqsb

zlaqsb equilibrates a symmetric band matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqsb(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void zlaqsb_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             const double *s, const double *scond, const double *amax,
             char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is DOUBLE PRECISION

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqsb*, *dlaqsb* and *slaqsb*.

4.17.738 zlaqsp

`zlaqsp` equilibrates a symmetric matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqsp(UPLO, N, AP, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void zlaqsp_(const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, const double *s, const double *scond,
             const double *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

AP Input and output parameter.

`AP` is `COMPLEX*16`

`AP` is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array `AP` as follows: if `UPLO` = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if `UPLO` = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the equilibrated matrix: diag(`S`) * A * diag(`S`), in the same storage format as A.

S Input parameter.

`S` is `DOUBLE PRECISION`

`S` is an array, dimension (`N`). The scale factors for A.

SCOND Input parameter.

`SCOND` is `DOUBLE PRECISION`

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

`AMAX` is `DOUBLE PRECISION`

Absolute value of largest matrix entry.

EQUED Output parameter.

`EQUED` is `CHARACTER*1`

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqsp*, *dlaqsp* and *slaqsp*.

4.17.739 zlaqsy

zlaqsy equilibrates a symmetric matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaqsy(UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void zlaqsy_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const double *s, const double *scond,
             const double *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if EQUED = 'Y', the equilibrated matrix: diag(S) * A * diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is DOUBLE PRECISION

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is DOUBLE PRECISION

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *claqsy*, *dlaqsy* and *slaqsy*.

4.17.740 zlar1v

zlar1v computes the (scaled) r-th column of the inverse of the sumbmatrix in rows B1 through BN of the tridiagonal matrix L D L^T - sigma I. When sigma is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, r corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation : (a) Stationary qd transform, L D L^T - sigma I = L(+) D(+) $L(+)^T$, (b) Progressive qd transform, L D L^T - sigma I = U(-) D(-) $U(-)^T$, (c) Computation of the diagonal elements of the inverse of

```
L D L**T - sigma I by combining the above transforms, and choosing
r as the index where the diagonal of the inverse is (one of the)
largest in magnitude.
```

(d) Computation of the (scaled) r-th column of the inverse using the

```
twisted factorization obtained by combining the top part of the
the stationary and the bottom part of the progressive transform.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlar1v(N, B1, BN, LAMBDA, D, L, LD, LLD, PIVMIN, GAPTOL, Z, WANTNC,
                  NEGCNT, ZTZ, MINGMA, R, ISUPPZ, NRMINV, RESID, RQCORR,
                  WORK)
```

C specification:

```
#include "armpl.h"

void zlar1v_(const armpl_int_t *n, const armpl_int_t *b1,
             const armpl_int_t *bn, const double *lambda, const double *d,
```

(continues on next page)

(continued from previous page)

```
                const double *l, const double *ld, const double *lld,
                const double *pivmin, const double *gaptol,
                armpl_doublecomplex_t *z, const armpl_int_t *wantnc,
                armpl_int_t *negcnt, double *ztz, double *mingma, armpl_int_t *r,
                armpl_int_t *isuppz, double *nrminv, double *resid,
                double *rqcorr, double *work);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix L D L^T .

B1 Input parameter.

B1 is INTEGER

First index of the submatrix of L D L^T .

BN Input parameter.

BN is INTEGER

Last index of the submatrix of L D L^T .

LAMBDA Input parameter.

LAMBDA is DOUBLE PRECISION

The shift. In order to compute an accurate eigenvector, LAMBDA should be a good approximation to an eigenvalue of L D L^T .

L Input parameter.

L is DOUBLE PRECISION

L is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal matrix L, in elements 1 to N-1.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D.

LD Input parameter.

LD is DOUBLE PRECISION

LD is an array, dimension (N-1). The n-1 elements L(i)*D(i).

LLD Input parameter.

LLD is DOUBLE PRECISION

LLD is an array, dimension (N-1). The n-1 elements L(i)*L(i)*D(i).

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot in the Sturm sequence.

GAPTOL Input parameter.

GAPTOL is DOUBLE PRECISION

Tolerance that indicates when eigenvector entries are negligible w.r.t. their contribution to the residual.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (N). On input, all entries of Z must be set to 0. On output, Z contains the (scaled) r-th column of the inverse. The scaling is such that Z(R) equals 1.

WANTNC Input parameter.

WANTNC is LOGICAL

Specifies whether NEGCNT has to be computed.

NEGCNT Output parameter.

NEGCNT is INTEGER

If WANTNC is .TRUE. then NEGCNT = the number of pivots < pivmin in the matrix factorization L D L^T , and NEGCNT = -1 otherwise.

ZTZ Output parameter.

ZTZ is DOUBLE PRECISION

The square of the 2-norm of Z.

MINGMA Output parameter.

MINGMA is DOUBLE PRECISION

The reciprocal of the largest (in magnitude) diagonal element of the inverse of L D L^T - sigma I.

R Input and output parameter.

R is INTEGER

The twist index for the twisted factorization used to compute Z. On input, 0 <= R <= N. If R is input as 0, R is set to the index where (L D L^T - sigma I)^{-1} is largest in magnitude. If 1 <= R <= N, R is unchanged. On output, R contains the twist index used to compute Z. Ideally, R designates the position of the maximum entry in the eigenvector.

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2)

The support of the vector in Z, i.e., the vector Z is nonzero only in elements ISUPPZ(1) through ISUPPZ(2).

NRMINV Output parameter.

NRMINV is DOUBLE PRECISION

NRMINV = 1/SQRT(ZTZ)

RESID Output parameter.

RESID is DOUBLE PRECISION

The residual of the FP vector. RESID = ABS(MINGMA)/SQRT(ZTZ)

RQCORR Output parameter.

RQCORR is DOUBLE PRECISION

The Rayleigh Quotient correction to LAMBDA. RQCORR = MINGMA*TMP

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

Related Information

For this routine in other precisions, please see *clar1v*, *dlar1v* and *slar1v*.

4.17.741 zlar2v

`zlar2v` applies a vector of complex plane rotations with real cosines from both sides to a sequence of 2-by-2 complex Hermitian matrices, defined by the elements of the vectors x, y and z. For i = 1,2,...,n

```
(       x(i)  z(i) ) :=
( conjg(z(i)) y(i) )

  (  c(i) conjg(s(i)) ) (       x(i)  z(i) ) ( c(i) -conjg(s(i)) )
  ( -s(i)       c(i)  ) ( conjg(z(i)) y(i) ) ( s(i)        c(i)  )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlar2v(N, X, Y, Z, INCX, C, S, INCC)
```

C specification:

```
#include "armpl.h"

void zlar2v_(const armpl_int_t *n, armpl_doublecomplex_t *x,
             armpl_doublecomplex_t *y, armpl_doublecomplex_t *z,
             const armpl_int_t *incx, const double *c,
             const armpl_doublecomplex_t *s, const armpl_int_t *incc);
```

Parameters

N Input parameter.

`N` is `INTEGER`

The number of plane rotations to be applied.

X Input and output parameter.

`X` is `COMPLEX*16`

`X` is an array, dimension (1+(N-1)*INCX). The vector x; the elements of x are assumed to be real.

Y Input and output parameter.

`Y` is `COMPLEX*16`

`Y` is an array, dimension (1+(N-1)*INCX). The vector y; the elements of y are assumed to be real.

Z Input and output parameter.

`Z` is `COMPLEX*16`

`Z` is an array, dimension (1+(N-1)*INCX). The vector z.

INCX Input parameter.

`INCX` is `INTEGER`

The increment between elements of `X`, `Y` and `Z`. `INCX` > 0.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

S Input parameter.

S is COMPLEX*16

S is an array, dimension (1+(N-1)*INCC). The sines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C and S. INCC > 0.

Related Information

For this routine in other precisions, please see *clar2v*, *dlar2v* and *slar2v*.

4.17.742 zlarcm

zlarcm performs a very simple matrix-matrix multiplication:

```
C := A * B,
```

where A is M by M and real; B is M by N and complex; C is M by N and complex.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarcm(M, N, A, LDA, B, LDB, C, LDC, RWORK)
```

C specification:

```
#include "armpl.h"

void zlarcm_(const armpl_int_t *m, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, double *rwork);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A and of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns and rows of the matrix B and the number of columns of the matrix C. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, M). On entry, A contains the M by M matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >=max(1, M).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, B contains the M by N matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >=max(1, M).

C Output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On exit, C contains the M by N matrix C.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >=max(1, M).

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*M*N) .

Related Information

For this routine in other precisions, please see *clarcm*. It also exists with a native C interface as *LAPACKE_zlarcm*.

4.17.743 zlarf

zlarf applies a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**H
```

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H^H , supply conjg(tau) instead tau.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarf(SIDE, M, N, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void zlarf_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_doublecomplex_t *v, const armpl_int_t *incv,
            const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
            const armpl_int_t *ldc, armpl_doublecomplex_t *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

V Input parameter.

V is COMPLEX*16

V is an array, dimension. (1 + (M-1)*abs(INCV)) if SIDE = 'L' or (1 + (N-1)*abs(INCV)) if SIDE = 'R' The vector v in the representation of H. V is not used if TAU = 0.

INCV Input parameter.

INCV is INTEGER

The increment between elements of v. INCV <> 0.

TAU Input parameter.

TAU is COMPLEX*16

The value tau in the representation of H.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R'

Related Information

For this routine in other precisions, please see *clarf*, *dlarf* and *slarf*.

4.17.744 zlarfb

`zlarfb` applies a complex block reflector H or its transpose H^H to a complex M-by-N matrix C, from either the left or the right.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarfb(SIDE, TRANS, DIRECT, STOREV, M, N, K, V, LDV, T, LDT, C,
                  LDC, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void zlarfb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_doublecomplex_t *v,
             const armpl_int_t *ldv, const armpl_doublecomplex_t *t,
             const armpl_int_t *ldt, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             const armpl_int_t *ldwork, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^H from the Left = 'R': apply H or H^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'C': apply H^H (Conjugate transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columnwise = 'R': Rowwise

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

K Input parameter.

K is INTEGER

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

V Input parameter.

V is COMPLEX*16

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, M) if STOREV = 'R' and SIDE = 'L' (LDV, N) if STOREV = 'R' and SIDE = 'R' See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C' and SIDE = 'L', LDV >= max(1, M); if STOREV = 'C' and SIDE = 'R', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

T Input parameter.

T is COMPLEX*16

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by H* C or H^H * C or C*H or C*H^H .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LDWORK, K) .

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1, N); if SIDE = 'R', LDWORK >= max(1, M).

Related Information

For this routine in other precisions, please see *clarfb*, *dlarfb* and *slarfb*. It also exists with a native C interface as *LAPACKE_zlarfb*.

4.17.745 zlarfg

zlarfg generates a complex elementary reflector H of order n, such that

```
H**H * ( alpha ) = ( beta ),   H**H * H = I.
       (   x   )   (   0  )
```

where alpha and beta are scalars, with beta real, and x is an (n-1)-element complex vector. H is represented in the form

```
H = I - tau * ( 1 ) * ( 1 v**H ) ,
              ( v )
```

where tau is a complex scalar and v is a complex (n-1)-element vector. Note that H is not hermitian.

If the elements of x are all zero and alpha is real, then tau = 0 and H is taken to be the unit matrix.

Otherwise 1 <= real(tau) <= 2 and abs(tau-1) <= 1 .

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarfg(N, ALPHA, X, INCX, TAU)
```

C specification:

```
#include "armpl.h"

void zlarfg_(const armpl_int_t *n, armpl_doublecomplex_t *alpha,
             armpl_doublecomplex_t *x, const armpl_int_t *incx,
             armpl_doublecomplex_t *tau);
```

Parameters

N Input parameter.

N is INTEGER

The order of the elementary reflector.

ALPHA Input and output parameter.

ALPHA is COMPLEX*16

On entry, the value alpha. On exit, it is overwritten with the value beta.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension. (1+(N-2)*abs(INCX)) On entry, the vector x. On exit, it is overwritten with the vector v.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

TAU Output parameter.

TAU is COMPLEX*16

The value tau.

Related Information

For this routine in other precisions, please see *clarfg*, *dlarfg* and *slarfg*. It also exists with a native C interface as *LAPACKE_zlarfg*.

4.17.746 zlarfgp

zlarfgp generates a complex elementary reflector H of order n, such that

```
H**H * ( alpha ) = ( beta ),   H**H * H = I.
       (   x   )   (   0  )
```

where alpha and beta are scalars, beta is real and non-negative, and x is an (n-1)-element complex vector. H is represented in the form

```
H = I - tau * ( 1 ) * ( 1 v**H ) ,
              ( v )
```

where tau is a complex scalar and v is a complex (n-1)-element vector. Note that H is not hermitian.

If the elements of x are all zero and alpha is real, then tau = 0 and H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarfgp(N, ALPHA, X, INCX, TAU)
```

C specification:

```
#include "armpl.h"

void zlarfgp_(const armpl_int_t *n, armpl_doublecomplex_t *alpha,
              armpl_doublecomplex_t *x, const armpl_int_t *incx,
              armpl_doublecomplex_t *tau);
```

Parameters

N Input parameter.

N is INTEGER

The order of the elementary reflector.

ALPHA Input and output parameter.

ALPHA is COMPLEX*16

On entry, the value alpha. On exit, it is overwritten with the value beta.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension. (1+(N-2)*abs(INCX)) On entry, the vector x. On exit, it is overwritten with the vector v.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

TAU Output parameter.

TAU is COMPLEX*16

The value tau.

Related Information

For this routine in other precisions, please see *clarfgp*, *dlarfgp* and *slarfgp*.

4.17.747 zlarft

`zlarft` forms the triangular factor T of a complex block reflector H of order n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

```
H  =  I - V * T * V**H
```

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

```
H  =  I - V**H * T * V
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarft(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

C specification:

```
#include "armpl.h"

void zlarft_(const char *direct, const char *storev, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_doublecomplex_t *v,
             const armpl_int_t *ldv, const armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *t, const armpl_int_t *ldt, ... );
```

Parameters

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details): = 'C': columnwise = 'R': rowwise

N Input parameter.

N is INTEGER

The order of the block reflector H. N >= 0.

K Input parameter.

K is INTEGER

The order of the triangular factor T (= the number of elementary reflectors). K >= 1.

V Input parameter.

V is COMPLEX*16

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, N) if STOREV = 'R' The matrix V. See further details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, K). The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

Related Information

For this routine in other precisions, please see *clarft*, *dlarft* and *slarft*. It also exists with a native C interface as *LAPACKE_zlarft*.

4.17.748 zlarfx

zlarfx applies a complex elementary reflector H to a complex m by n matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**H
```

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix

This version uses inline code if H has order < 11.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarfx(SIDE, M, N, V, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void zlarfx_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_doublecomplex_t *v, const armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *c, const armpl_int_t *ldc,
             armpl_doublecomplex_t *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

V Input parameter.

V is COMPLEX*16

V is an array, dimension (M) if SIDE = 'L'. or (N) if SIDE = 'R' The vector v in the representation of H.

TAU Input parameter.

TAU is COMPLEX*16

The value tau in the representation of H.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDA >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) if SIDE = 'L'. or (M) if SIDE = 'R' WORK is not referenced if H has order < 11.

Related Information

For this routine in other precisions, please see *clarfx*, *dlarfx* and *slarfx*. It also exists with a native C interface as *LAPACKE_zlarfx*.

4.17.749 zlarfy

zlarfy applies an elementary reflector, or Householder matrix, H, to an n x n Hermitian matrix C, from both the left and the right.

H is represented in the form

```
H = I - tau * v * v'
```

where tau is a scalar and v is a vector.

If tau is zero, then H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarfy(UPLO, N, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void zlarfy_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *v, const armpl_int_t *incv,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix C is stored. = 'U': Upper triangle = 'L': Lower triangle

N Input parameter.

N is INTEGER

The number of rows and columns of the matrix C. N >= 0.

V Input parameter.

V is COMPLEX*16

V is an array, dimension. (1 + (N-1)*abs(INCV)) The vector v as described above.

INCV Input parameter.

INCV is INTEGER

The increment between successive elements of v. INCV must not be zero.

TAU Input parameter.

TAU is COMPLEX*16

The value tau as described above.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the matrix C. On exit, C is overwritten by H * C * H'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

Related Information

For this routine in other precisions, please see *clarfy*, *dlarfy* and *slarfy*.

4.17.750 zlargv

zlargv generates a vector of complex plane rotations with real cosines, determined by elements of the complex vectors x and y. For i = 1,2,...,n

```
(        c(i)   s(i) ) ( x(i) ) = ( r(i) )
( -conjg(s(i))  c(i) ) ( y(i) ) = (   0  )

where c(i)**2 + ABS(s(i))**2 = 1
```

The following conventions are used (these are the same as in ZLARTG, but differ from the BLAS1 routine ZROTG):

```
If y(i)=0, then c(i)=1 and s(i)=0.
If x(i)=0, then c(i)=0 and s(i) is chosen so that r(i) is real.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlargv(N, X, INCX, Y, INCY, C, INCC)
```

C specification:

```
#include "armpl.h"

void zlargv_(const armpl_int_t *n, armpl_doublecomplex_t *x,
             const armpl_int_t *incx, armpl_doublecomplex_t *y,
             const armpl_int_t *incy, double *c, const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be generated.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (1+(N-1)*INCX). On entry, the vector x. On exit, x(i) is overwritten by r(i), for i = 1,...,n.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension (1+(N-1)*INCY). On entry, the vector y. On exit, the sines of the plane rotations.

INCY Input parameter.

INCY is INTEGER

The increment between elements of Y. INCY > 0.

C Output parameter.

C is DOUBLE PRECISION

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C. INCC > 0.

Related Information

For this routine in other precisions, please see *clargv*, *dlargv* and *slargv*.

4.17.751 zlarnv

zlarnv returns a vector of n random complex numbers from a uniform or normal distribution.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarnv(IDIST, ISEED, N, X)
```

C specification:

```
#include "armpl.h"

void zlarnv_(const armpl_int_t *idist, armpl_int_t *iseed,
             const armpl_int_t *n, armpl_doublecomplex_t *x);
```

Parameters

IDIST Input parameter.

IDIST is INTEGER

Specifies the distribution of the random numbers: = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc abs(z) < 1 = 5: uniformly distributed on the circle abs(z) = 1

ISEED Input and output parameter.

ISEED is INTEGER array, dimension (4)

On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and ISEED(4) must be odd. On exit, the seed is updated.

N Input parameter.

N is INTEGER

The number of random numbers to be generated.

X Output parameter.

X is COMPLEX*16

X is an array, dimension (N). The generated random numbers.

Related Information

For this routine in other precisions, please see *clarnv*, *dlarnv* and *slarnv*. It also exists with a native C interface as *LAPACKE_zlarnv*.

4.17.752 zlarrv

zlarrv computes the eigenvectors of the tridiagonal matrix T = L D L^T given L, D and APPROXIMATIONS to the eigenvalues of L D L^T . The input eigenvalues should have been computed by DLARRE.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarrv(N, VL, VU, D, L, PIVMIN, ISPLIT, M, DOL, DOU, MINRGP, RTOL1,
                  RTOL2, W, WERR, WGAP, IBLOCK, INDEXW, GERS, Z, LDZ, ISUPPZ,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlarrv_(const armpl_int_t *n, const double *vl, const double *vu,
             double *d, double *l, double *pivmin, const armpl_int_t *isplit,
             const armpl_int_t *m, const armpl_int_t *dol,
             const armpl_int_t *dou, const double *minrgp,
             const double *rtol1, const double *rtol2, double *w,
             double *werr, double *wgap, const armpl_int_t *iblock,
             const armpl_int_t *indexw, const double *gers,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *isuppz, double *work, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

VL Input parameter.

VL is DOUBLE PRECISION

Lower bound of the interval that contains the desired eigenvalues. VL < VU. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired RANGE.

VU Input parameter.

VU is DOUBLE PRECISION

Upper bound of the interval that contains the desired eigenvalues. VL < VU. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired RANGE.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the N diagonal elements of the diagonal matrix D. On exit, D may be overwritten.

L Input and output parameter.

L is DOUBLE PRECISION

L is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the unit bidiagonal matrix L are in elements 1 to N-1 of L (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by DLARRE. On exit, L is overwritten.

PIVMIN Input parameter.

PIVMIN is DOUBLE PRECISION

The minimum pivot allowed in the Sturm sequence.

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc.

M Input parameter.

M is INTEGER

The total number of input eigenvalues. 0 <= M <= N.

DOL Input parameter.

DOL is INTEGER

DOU Input parameter.

DOU is INTEGER

If the user wants to compute only selected eigenvectors from all the eigenvalues supplied, he can specify an index range DOL:DOU. Or else the setting DOL=1, DOU=M should be applied. Note that DOL and DOU refer to the order in which the eigenvalues are stored in W. If the user wants to compute only selected eigenpairs, then the columns DOL-1 to DOU+1 of the eigenvector space Z contain the computed eigenvectors. All other columns of Z are set to zero.

MINRGP Input parameter.

MINRGP is DOUBLE PRECISION

RTOL1 Input parameter.

RTOL1 is DOUBLE PRECISION

RTOL2 Input parameter.

RTOL2 is DOUBLE PRECISION

Parameters for bisection. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|))

W Input and output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements of W contain the APPROXIMATE eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block (The output array W from DLARRE is expected here). Furthermore, they are with respect to the shift of the corresponding root representation for their block. On exit, W holds the eigenvalues of the UNshifted matrix.

WERR Input and output parameter.

WERR is DOUBLE PRECISION

WERR is an array, dimension (N). The first M elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in W

WGAP Input and output parameter.

WGAP is DOUBLE PRECISION

WGAP is an array, dimension (N). The separation from the right neighbor eigenvalue in W.

IBLOCK Input parameter.

IBLOCK is INTEGER array, dimension (N)

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first block from the top, =2 if W(i) belongs to the second block, etc.

INDEXW Input parameter.

INDEXW is INTEGER array, dimension (N)

The indices of the eigenvalues within each block (submatrix); for example, INDEXW(i)= 10 and IBLOCK(i)=2 imply that the i-th eigenvalue W(i) is the 10-th eigenvalue in the second block.

GERS Input parameter.

GERS is DOUBLE PRECISION

GERS is an array, dimension (2*N). The N Gerschgorin intervals (the i-th Gerschgorin interval is (GERS(2*i-1), GERS(2*i)). The Gerschgorin intervals should be computed from the original UNshifted matrix.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the input eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least max(1, M) columns are supplied in the array Z.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The I-th eigenvector is nonzero only in elements ISUPPZ(2*I-1) through ISUPPZ(2*I).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (12*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (7*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

> 0: A problem occurred in ZLARRV. < 0: One of the called subroutines signaled an internal problem. Needs inspection of the corresponding parameter IINFO for further information.

=-1: Problem in DLARRB when refining a child's eigenvalues. =-2: Problem in DLARRF when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter MINRGP smaller and recompile. However, as the orthogonality of the computed vectors is proportional to 1/MINRGP, the user should be aware that he might be trading in precision when he decreases MINRGP. =-3: Problem in DLARRB when refining a single eigenvalue after the Rayleigh correction was rejected. = 5: The Rayleigh Quotient Iteration failed to converge to full accuracy in MAXITR steps.

Related Information

For this routine in other precisions, please see *clarrv*, *dlarrv* and *slarrv*.

4.17.753 zlarscl2

ZLARSCL2 performs a reciprocal diagonal scaling on an vector:

```
x <-- inv(D) * x
```

where the DOUBLE PRECISION diagonal matrix D is stored as a vector.

Eventually to be replaced by BLAS_zge_diag_scale in the new BLAS standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarscl2(M, N, D, X, LDX)
```

C specification:

```
#include "armpl.h"

void zlarscl2_(const armpl_int_t *m, const armpl_int_t *n, const double *d,
               armpl_doublecomplex_t *x, const armpl_int_t *ldx);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of D and X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of X. N >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, length M. Diagonal matrix D, stored as a vector of length M.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, N). On entry, the vector X to be scaled by D. On exit, the scaled vector.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the vector X. LDX >= M.

4.17.754 zlartg

zlartg generates a plane rotation so that

```
[  CS  SN  ]     [ F ]     [ R ]
[  __      ]  .  [   ]  =  [   ]   where CS**2 + |SN|**2 = 1.
[ -SN  CS  ]     [ G ]     [ 0 ]
```

This is a faster version of the BLAS1 routine ZROTG, except for the following differences:

```
 F and G are unchanged on return.
If G=0, then CS=1 and SN=0.
If F=0, then CS=0 and SN is chosen so that R is real.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlartg(F, G, CS, SN, R)
```

C specification:

```
#include "armpl.h"

void zlartg_(const armpl_doublecomplex_t *f, const armpl_doublecomplex_t *g,
             double *cs, armpl_doublecomplex_t *sn,
             armpl_doublecomplex_t *r);
```

Parameters

F Input parameter.

F is COMPLEX*16

The first component of vector to be rotated.

G Input parameter.

G is COMPLEX*16

The second component of vector to be rotated.

CS Output parameter.

CS is DOUBLE PRECISION

The cosine of the rotation.

SN Output parameter.

SN is COMPLEX*16

The sine of the rotation.

R Output parameter.

R is COMPLEX*16

The nonzero component of the rotated vector.

Related Information

For this routine in other precisions, please see *clartg*, *dlartg* and *slartg*.

4.17.755 zlartv

zlartv applies a vector of complex plane rotations with real cosines to elements of the complex vectors x and y. For i = 1,2,...,n

```
( x(i) ) := (         c(i)   s(i) ) ( x(i) )
( y(i) )    ( -conjg(s(i))   c(i) ) ( y(i) )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zlartv(N, X, INCX, Y, INCY, C, S, INCC)
```

C specification:

```
#include "armpl.h"

void zlartv_(const armpl_int_t *n, armpl_doublecomplex_t *x,
             const armpl_int_t *incx, armpl_doublecomplex_t *y,
             const armpl_int_t *incy, const double *c,
             const armpl_doublecomplex_t *s, const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be applied.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (1+(N-1)*INCX). The vector x.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

Y Input and output parameter.

Y is COMPLEX*16

Y is an array, dimension (1+(N-1)*INCY). The vector y.

INCY Input parameter.

INCY is INTEGER

The increment between elements of Y. INCY > 0.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

S Input parameter.

S is COMPLEX*16

S is an array, dimension (1+(N-1)*INCC). The sines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C and S. INCC > 0.

Related Information

For this routine in other precisions, please see *clartv*, *dlartv* and *slartv*.

4.17.756 zlarz

zlarz applies a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**H
```

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H^H (the conjugate transpose of H), supply conjg(tau) instead tau.

H is a product of k elementary reflectors as returned by ZTZRZF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarz(SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void zlarz_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *l, const armpl_doublecomplex_t *v,
            const armpl_int_t *incv, const armpl_doublecomplex_t *tau,
            armpl_doublecomplex_t *c, const armpl_int_t *ldc,
            armpl_doublecomplex_t *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

L Input parameter.

L is INTEGER

The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V Input parameter.

V is COMPLEX*16

V is an array, dimension (1+(L-1)*abs(INCV)). The vector v in the representation of H as returned by ZTZRZF. V is not used if TAU = 0.

INCV Input parameter.

INCV is INTEGER

The increment between elements of v. INCV <> 0.

TAU Input parameter.

TAU is COMPLEX*16

The value tau in the representation of H.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R'

Related Information

For this routine in other precisions, please see *clarz*, *dlarz* and *slarz*.

4.17.757 zlarzb

zlarzb applies a complex block reflector H or its transpose H^H to a complex distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarzb(SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV, T, LDT, C,
                  LDC, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void zlarzb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l,
             const armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             const armpl_doublecomplex_t *t, const armpl_int_t *ldt,
             armpl_doublecomplex_t *c, const armpl_int_t *ldc,
             armpl_doublecomplex_t *work, const armpl_int_t *ldwork, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^H from the Left = 'R': apply H or H^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'C': apply H^H (Conjugate transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columnwise (not supported yet) = 'R': Rowwise

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

K Input parameter.

K is INTEGER

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L Input parameter.

L is INTEGER

The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V Input parameter.

V is COMPLEX*16

V is an array, dimension (LDV,NV).. If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= L; if STOREV = 'R', LDV >= K.

T Input parameter.

T is COMPLEX*16

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by H* C or H^H * C or C*H or C*H^H .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LDWORK, K) .

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1, N); if SIDE = 'R', LDWORK >= max(1, M).

Related Information

For this routine in other precisions, please see *clarzb*, *dlarzb* and *slarzb*.

4.17.758 zlarzt

zlarzt forms the triangular factor T of a complex block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

```
H  =  I - V * T * V**H
```

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

```
H  =  I - V**H * T * V
```

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlarzt(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

C specification:

```
#include "armpl.h"

void zlarzt_(const char *direct, const char *storev, const armpl_int_t *n,
             const armpl_int_t *k, armpl_doublecomplex_t *v,
             const armpl_int_t *ldv, const armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *t, const armpl_int_t *ldt, ... );
```

Parameters

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details): = 'C': columnwise (not supported yet) = 'R': rowwise

N Input parameter.

N is INTEGER

The order of the block reflector H. N >= 0.

K Input parameter.

K is INTEGER

The order of the triangular factor T (= the number of elementary reflectors). K >= 1.

V Input and output parameter.

V is COMPLEX*16

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, N) if STOREV = 'R' The matrix V. See further details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, K). The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

Related Information

For this routine in other precisions, please see *clarzt*, *dlarzt* and *slarzt*.

4.17.759 zlascl

zlascl multiplies the M by N complex matrix A by the real scalar CTO/CFROM. This is done without over/underflow as long as the final result CTO*A(I,J)/CFROM does not over/underflow. TYPE specifies that A may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlascl(TYPE, KL, KU, CFROM, CTO, M, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void zlascl_(const char *type, const armpl_int_t *kl, const armpl_int_t *ku,
             const double *cfrom, const double *cto, const armpl_int_t *m,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

TYPE Input parameter.

TYPE is CHARACTER*1

TYPE indices the storage type of the input matrix. = 'G': A is a full matrix. = 'L': A is a lower triangular matrix. = 'U': A is an upper triangular matrix. = 'H': A is an upper Hessenberg matrix. = 'B': A is a symmetric band matrix with lower bandwidth KL and upper bandwidth KU and with the only the lower half stored. = 'Q': A is a symmetric band matrix with lower bandwidth KL and upper bandwidth KU and with the only the upper half stored. = 'Z': A is a band matrix with lower bandwidth KL and upper bandwidth KU. See ZGBTRF for storage details.

KL Input parameter.

KL is INTEGER

The lower bandwidth of A. Referenced only if TYPE = 'B', 'Q' or 'Z'.

KU Input parameter.

KU is INTEGER

The upper bandwidth of A. Referenced only if TYPE = 'B', 'Q' or 'Z'.

CFROM Input parameter.

CFROM is DOUBLE PRECISION

CTO Input parameter.

CTO is DOUBLE PRECISION

The matrix A is multiplied by CTO/CFROM. A(I,J) is computed without over/underflow if the final result CTO*A(I,J)/CFROM can be represented without over/underflow. CFROM must be nonzero.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The matrix to be multiplied by CTO/CFROM. See TYPE for the storage type.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If TYPE = 'G', 'L', 'U', 'H', LDA >= max(1, M); TYPE = 'B', LDA >= KL+1; TYPE = 'Q', LDA >= KU+1; TYPE = 'Z', LDA >= 2*KL+KU+1.

INFO Output parameter.

INFO is INTEGER

0 - successful exit <0 - if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *clascl*, *dlascl* and *slascl*. It also exists with a native C interface as *LAPACKE_zlascl*.

4.17.760 zlascl2

zlascl2 performs a diagonal scaling on a vector:

```
x <-- D * x
```

where the DOUBLE PRECISION diagonal matrix D is stored as a vector.

Eventually to be replaced by BLAS_zge_diag_scale in the new BLAS standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlascl2(M, N, D, X, LDX)
```

C specification:

```
#include "armpl.h"

void zlascl2_(const armpl_int_t *m, const armpl_int_t *n, const double *d,
              armpl_doublecomplex_t *x, const armpl_int_t *ldx);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of D and X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of X. N >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, length M. Diagonal matrix D, stored as a vector of length M.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, N). On entry, the vector X to be scaled by D. On exit, the scaled vector.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the vector X. LDX >= M.

Related Information

For this routine in other precisions, please see *clascl2*, *dlascl2* and *slascl2*.

4.17.761 zlaset

zlaset initializes a 2-D array A to BETA on the diagonal and ALPHA on the offdiagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaset(UPLO, M, N, ALPHA, BETA, A, LDA)
```

C specification:

```
#include "armpl.h"

void zlaset_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_doublecomplex_t *alpha,
             const armpl_doublecomplex_t *beta, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be set. = 'U': Upper triangular part is set. The lower triangle is unchanged. = 'L': Lower triangular part is set. The upper triangle is unchanged. Otherwise: All of the matrix A is set.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of A.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of A.

ALPHA Input parameter.

ALPHA is COMPLEX*16

All the offdiagonal array elements are set to ALPHA.

BETA Input parameter.

BETA is COMPLEX*16

All the diagonal array elements are set to BETA.

A Output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, A(i,j) = ALPHA, 1 <= i <= m, 1 <= j <= n, i.ne.j; A(i,i) = BETA , 1 <= i <= min(m,n)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

For this routine in other precisions, please see *claset*, *dlaset* and *slaset*. It also exists with a native C interface as *LAPACKE_zlaset*.

4.17.762 zlasr

zlasr applies a sequence of real plane rotations to a complex matrix A, from either the left or the right.

When SIDE = 'L', the transformation takes the form

```
A := P*A
```

and when SIDE = 'R', the transformation takes the form

```
A := A*P**T
```

where P is an orthogonal matrix consisting of a sequence of z plane rotations, with z = M when SIDE = 'L' and z = N when SIDE = 'R', and P^T is the transpose of P.

When DIRECT = 'F' (Forward sequence), then

```
P = P(z-1) * ... * P(2) * P(1)
```

and when DIRECT = 'B' (Backward sequence), then

```
P = P(1) * P(2) * ... * P(z-1)
```

where P(k) is a plane rotation matrix defined by the 2-by-2 rotation

```
R(k) = (  c(k)   s(k) )
     = ( -s(k)   c(k) ).
```

When PIVOT = 'V' (Variable pivot), the rotation is performed for the plane (k,k+1), i.e., P(k) has the form

```
P(k) = (  1                                          )
       (       ...                                   )
       (              1                              )
       (                    c(k)   s(k)              )
```

(continues on next page)

(continued from previous page)

```
(                   -s(k)   c(k)                    )
(                                1                  )
(                                     ...           )
(                                           1       )
```

where R(k) appears as a rank-2 modification to the identity matrix in rows and columns k and k+1.

When PIVOT = 'T' (Top pivot), the rotation is performed for the plane (1,k+1), so P(k) has the form

```
P(k) = (  c(k)                      s(k)                  )
       (          1                                       )
       (                ...                               )
       (                        1                         )
       ( -s(k)                  c(k)                      )
       (                                1                 )
       (                                     ...          )
       (                                           1      )
```

where R(k) appears in rows and columns 1 and k+1.

Similarly, when PIVOT = 'B' (Bottom pivot), the rotation is performed for the plane (k,z), giving P(k) the form

```
P(k) = ( 1                                              )
       (       ...                                      )
       (               1                                )
       (                     c(k)                s(k)   )
       (                             1                  )
       (                                  ...           )
       (                                        1       )
       (                    -s(k)                c(k)   )
```

where R(k) appears in rows and columns k and z. The rotations are performed without ever forming P(k) explicitly.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlasr(SIDE, PIVOT, DIRECT, M, N, C, S, A, LDA)
```

C specification:

```
#include "armpl.h"

void zlasr_(const char *side, const char *pivot, const char *direct,
            const armpl_int_t *m, const armpl_int_t *n, const double *c,
            const double *s, armpl_doublecomplex_t *a, const armpl_int_t *lda,
            ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

Specifies whether the plane rotation matrix P is applied to A on the left or the right. = 'L': Left, compute A := P*A = 'R': Right, compute A:= A*P^T

PIVOT Input parameter.

PIVOT is CHARACTER*1

Specifies the plane for which P(k) is a plane rotation matrix. = 'V': Variable pivot, the plane (k,k+1) = 'T': Top pivot, the plane (1,k+1) = 'B': Bottom pivot, the plane (k,z)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies whether P is a forward or backward sequence of plane rotations. = 'F': Forward, P = P(z-1)*...*P(2)*P(1) = 'B': Backward, P = P(1)*P(2)*...*P(z-1)

M Input parameter.

M is INTEGER

The number of rows of the matrix A. If m <= 1, an immediate return is effected.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. If n <= 1, an immediate return is effected.

C Input parameter.

C is DOUBLE PRECISION

C is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' The cosines c(k) of the plane rotations.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' The sines s(k) of the plane rotations. The 2-by-2 plane rotation part of the matrix P(k), R(k), has the form R(k) = (c(k) s(k)) (-s(k) c(k)).

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The M-by-N matrix A. On exit, A is overwritten by P* A if SIDE = 'R' or by A*P^T if SIDE = 'L'.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

4.17.763 zlassq

zlassq returns the values scl and ssq such that

```
( scl**2 )*ssq = x( 1 )**2 +...+ x( n )**2 + ( scale**2 )*sumsq,
```

where x(i) = abs(X(1 + (i - 1)*INCX)). The value of sumsq is assumed to be at least unity and the value of ssq will then satisfy

```
1.0 .le. ssq .le. ( sumsq + 2*n ).
```

scale is assumed to be non-negative and scl returns the value

```
scl = max( scale, abs( real( x( i ) ) ), abs( aimag( x( i ) ) ) ),
      i
```

scale and sumsq must be supplied in SCALE and SUMSQ respectively. SCALE and SUMSQ are overwritten by scl and ssq respectively.

The routine makes only one pass through the vector X.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlassq(N, X, INCX, SCALE, SUMSQ)
```

C specification:

```
#include "armpl.h"

void zlassq_(const armpl_int_t *n, const armpl_doublecomplex_t *x,
             const armpl_int_t *incx, double *scale, double *sumsq);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements to be used from the vector X.

X Input parameter.

X is COMPLEX*16

X is an array, dimension (N). The vector x as described above. x(i) = X(1 + (i - 1)* INCX), 1 <= i <= n.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of the vector X. INCX > 0.

SCALE Input and output parameter.

SCALE is DOUBLE PRECISION

On entry, the value scale in the equation above. On exit, SCALE is overwritten with the value scl .

SUMSQ Input and output parameter.

SUMSQ is DOUBLE PRECISION

On entry, the value sumsq in the equation above. On exit, SUMSQ is overwritten with the value ssq .

Related Information

For this routine in other precisions, please see *classq*, *dlassq* and *slassq*. It also exists with a native C interface as *LAPACKE_zlassq*.

4.17.764 zlaswlq

zlaswlq computes a blocked Short-Wide LQ factorization of a M-by-N matrix A, where N >= M: A = L * Q

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaswlq(M, N, MB, NB, A, LDA, T, LDT, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlaswlq_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *mb, const armpl_int_t *nb,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_doublecomplex_t *t, const armpl_int_t *ldt,
              armpl_doublecomplex_t *work, const armpl_int_t *lwork,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= M >= 0.

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. M >= MB >= 1

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. NB > M.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the N-by-N lower triangular matrix L; the elements above the diagonal represent Q by the rows of blocked V (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array,. dimension (LDT, N * Number_of_row_blocks) where Number_of_row_blocks = CEIL((N-M)/(NB-M)) The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details below.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

(workspace) COMPLEX*16

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

The dimension of the array WORK. LWORK >= MB*M.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *claswlq*, *dlaswlq* and *slaswlq*.

4.17.765 zlaswp

zlaswp performs a series of row interchanges on the matrix A. One row interchange is initiated for each of rows K1 through K2 of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlaswp(N, A, LDA, K1, K2, IPIV, INCX)
```

C specification:

```
#include "armpl.h"

void zlaswp_(const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_int_t *k1,
             const armpl_int_t *k2, const armpl_int_t *ipiv,
             const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the matrix of column dimension N to which the row interchanges will be applied. On exit, the permuted matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A.

K1 Input parameter.

K1 is INTEGER

The first element of IPIV for which a row interchange will be done.

K2 Input parameter.

K2 is INTEGER

(K2-K1+1) is the number of elements of IPIV for which a row interchange will be done.

IPIV Input parameter.

IPIV is INTEGER array, dimension (K1+(K2-K1)*abs(INCX))

The vector of pivot indices. Only the elements in positions K1 through K1+(K2-K1)*abs(INCX) of IPIV are accessed. IPIV(K1+(K-K1)*abs(INCX)) = L implies rows K and L are to be interchanged.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of IPIV. If INCX is negative, the pivots are applied in reverse order.

Related Information

For this routine in other precisions, please see *claswp*, *dlaswp* and *slaswp*. It also exists with a native C interface as *LAPACKE_zlaswp*.

4.17.766 zlasyf

zlasyf computes a partial factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L'

```
( L21  I ) ( 0   A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB. Note that U^T denotes the transpose of U.

zlasyf is an auxiliary routine called by ZSYTRF. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine zlasyf(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void zlasyf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             armpl_int_t *kb, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv,
             armpl_doublecomplex_t *w, const armpl_int_t *ldw,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *clasyf*, *dlasyf* and *slasyf*.

4.17.767 zlasyf_aa

DLATRF_AA factorizes a panel of a complex symmetric matrix A using the Aasen's algorithm. The panel consists of a set of NB rows of A when UPLO is U, or a set of NB columns when UPLO is L.

In order to factorize the panel, the Aasen's algorithm requires the last row, or column, of the previous panel. The first row, or column, of A is set to be the first row, or column, of an identity matrix, which is used to factorize the first panel.

The resulting J-th row of U, or J-th column of L, is stored in the (J-1)-th row, or column, of A (without the unit diagonals), while the diagonal and subdiagonal of A are overwritten by those of T.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlasyf_aa(UPLO, J1, M, NB, A, LDA, IPIV, H, LDH, WORK)
```

C specification:

```
#include "armpl.h"

void zlasyf_aa_(const char *uplo, const armpl_int_t *j1, const armpl_int_t *m,
                const armpl_int_t *nb, armpl_doublecomplex_t *a,
                const armpl_int_t *lda, armpl_int_t *ipiv,
```

(continues on next page)

(continued from previous page)

```
                armpl_doublecomplex_t *h, const armpl_int_t *ldh,
                armpl_doublecomplex_t *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

J1 Input parameter.

J1 is INTEGER

The location of the first row, or column, of the panel within the submatrix of A, passed to this routine, e.g., when called by ZSYTRF_AA, for the first panel, J1 is 1, while for the remaining panels, J1 is 2.

M Input parameter.

M is INTEGER

The dimension of the submatrix. M >= 0.

NB Input parameter.

NB is INTEGER

The dimension of the panel to be facotorized.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, M) for. the first panel, while dimension (LDA,M+1) for the remaining panels.

On entry, A contains the last row, or column, of the previous panel, and the trailing submatrix of A to be factorized, except for the first panel, only the panel is passed.

On exit, the leading panel is factorized.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (M)

Details of the row and column interchanges, the row and column k were interchanged with the row and column IPIV(k).

H Input and output parameter.

H is COMPLEX*16 workspace, dimension (LDH, NB).

LDH Input parameter.

LDH is INTEGER

The leading dimension of the workspace H. LDH >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16 workspace, dimension (M).

Related Information

For this routine in other precisions, please see *clasyf_aa*, *dlasyf_aa* and *slasyf_aa*.

4.17.768 zlasyf_rook

ZLASYF_ROOK computes a partial factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

ZLASYF_ROOK is an auxiliary routine called by ZSYTRF_ROOK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine zlasyf_rook(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void zlasyf_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nb, armpl_int_t *kb,
                  armpl_doublecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_doublecomplex_t *w,
                  const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *clasyf_rook*, *dlasyf_rook* and *slasyf_rook*.

4.17.769 zlat2c

`zlat2c` converts a COMPLEX*16 triangular matrix, SA, to a COMPLEX triangular matrix, A.

RMAX is the overflow for the SINGLE PRECISION arithmetic `zlat2c` checks that all the entries of A are between -RMAX and RMAX. If not the conversion is aborted and a flag is raised.

This is an auxiliary routine so there is no argument checking.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlat2c(UPLO, N, A, LDA, SA, LDSA, INFO)
```

C specification:

```
#include "armpl.h"

void zlat2c_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *sa, const armpl_int_t *ldsa,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= 'U': `A` is upper triangular; = 'L': `A` is lower triangular.

N Input parameter.

`N` is `INTEGER`

The number of rows and columns of the matrix `A`. `N` >= 0.

A Input parameter.

`A` is `COMPLEX*16`

`A` is an array, dimension (`LDA`, `N`). On entry, the N-by-N triangular coefficient matrix `A`.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `N`).

SA Output parameter.

`SA` is `COMPLEX`

`SA` is an array, dimension (`LDSA`, `N`). Only the `UPLO` part of `SA` is referenced. On exit, if INFO=0, the N-by-N coefficient matrix SA; if INFO>0, the content of the `UPLO` part of `SA` is unspecified.

LDSA Input parameter.

`LDSA` is `INTEGER`

The leading dimension of the array `SA`. `LDSA` >= max(1,M).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. = 1: an entry of the matrix A is greater than the SINGLE PRECISION overflow threshold, in this case, the content of the UPLO part of SA in exit is unspecified.

Related Information

4.17.770 zlatbs

zlatbs solves one of the triangular systems

```
A * x = s*b,  A**T * x = s*b,  or  A**H * x = s*b,
```

with scaling to prevent overflow, where A is an upper or lower triangular band matrix. Here A^T denotes the transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine ZTBSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlatbs(UPLO, TRANS, DIAG, NORMIN, N, KD, AB, LDAB, X, SCALE, CNORM,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zlatbs_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             armpl_doublecomplex_t *x, double *scale, double *cnorm,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^H * x = s*b (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of subdiagonals or superdiagonals in the triangular matrix A. KD >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

The scaling factor s for the triangular system A * x = s*b, A^T * x = s*b, or A^H * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is DOUBLE PRECISION

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatbs*, *dlatbs* and *slatbs*.

4.17.771 zlatdf

`zlatdf` computes the contribution to the reciprocal Dif-estimate by solving for x in Z * x = b, where b is chosen such that the norm of x is as large as possible. It is assumed that LU decomposition of Z has been computed by ZGETC2. On entry RHS = f holds the contribution from earlier solved sub-systems, and on return RHS = x.

The factorization of Z returned by ZGETC2 has the form Z = P * L * U * Q, where P and Q are permutation matrices. L is lower triangular with unit diagonal elements and U is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlatdf(IJOB, N, Z, LDZ, RHS, RDSUM, RDSCAL, IPIV, JPIV)
```

C specification:

```
#include "armpl.h"

void zlatdf_(const armpl_int_t *ijob, const armpl_int_t *n,
             const armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *rhs, double *rdsum, double *rdscal,
             const armpl_int_t *ipiv, const armpl_int_t *jpiv);
```

Parameters

IJOB Input parameter.

`IJOB` is `INTEGER`

`IJOB` = 2: First compute an approximative null-vector e of `Z` using ZGECON, e is normalized and solve for Zx = +-e - f with the sign giving the greater value of 2-norm(x). About 5 times as expensive as Default. `IJOB` .ne. 2: Local look ahead strategy where all entries of the r.h.s. b is chosen as either +1 or -1. Default.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `Z`.

Z Input parameter.

`Z` is `COMPLEX*16`

`Z` is an array, dimension (`LDZ`, N). On entry, the LU part of the factorization of the n-by-n matrix `Z` computed by ZGETC2: `Z` = P * L * U * Q

LDZ Input parameter.

`LDZ` is `INTEGER`

The leading dimension of the array `Z`. LDA >= max(1, N).

RHS Input and output parameter.

`RHS` is `COMPLEX*16`

`RHS` is an array, dimension (`N`).. On entry, `RHS` contains contributions from other subsystems. On exit, `RHS` contains the solution of the subsystem with entries according to the value of `IJOB` (see above).

RDSUM Input and output parameter.

`RDSUM` is `DOUBLE PRECISION`

On entry, the sum of squares of computed contributions to the Dif-estimate under computation by ZTGSYL, where the scaling factor RDSCAL (see below) has been factored out. On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If TRANS = 'T' RDSUM is not touched. NOTE: RDSUM only makes sense when ZTGSY2 is called by CTGSYL.

RDSCAL Input and output parameter.

RDSCAL is DOUBLE PRECISION

On entry, scaling factor used to prevent overflow in RDSUM. On exit, RDSCAL is updated w.r.t. the current contributions in RDSUM. If TRANS = 'T', RDSCAL is not touched. NOTE: RDSCAL only makes sense when ZTGSY2 is called by ZTGSYL.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Input parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

Related Information

4.17.772 zlatps

zlatps solves one of the triangular systems

```
A * x = s*b,  A**T * x = s*b,  or  A**H * x = s*b,
```

with scaling to prevent overflow, where A is an upper or lower triangular matrix stored in packed form. Here A^T denotes the transpose of A, A^H denotes the conjugate transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine ZTPSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlatps(UPLO, TRANS, DIAG, NORMIN, N, AP, X, SCALE, CNORM, INFO)
```

C specification:

```
#include "armpl.h"

void zlatps_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n,
             const armpl_doublecomplex_t *ap, armpl_doublecomplex_t *x,
             double *scale, double *cnorm, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^H * x = s*b (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

The scaling factor s for the triangular system A * x = s*b, A^T * x = s*b, or A^H * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is DOUBLE PRECISION

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatps*, *dlatps* and *slatps*.

4.17.773 zlatrd

`zlatrd` reduces NB rows and columns of a complex Hermitian matrix A to Hermitian tridiagonal form by a unitary similarity transformation Q^H * A * Q, and returns the matrices V and W which are needed to apply the transformation to the unreduced part of A.

If UPLO = 'U', `zlatrd` reduces the last NB rows and columns of a matrix, of which the upper triangle is supplied; if UPLO = 'L', `zlatrd` reduces the first NB rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by ZHETRD.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlatrd(UPLO, N, NB, A, LDA, E, TAU, W, LDW)
```

C specification:

```
#include "armpl.h"

void zlatrd_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             armpl_doublecomplex_t *a, const armpl_int_t *lda, double *e,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *w,
             const armpl_int_t *ldw, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A.

NB Input parameter.

NB is INTEGER

The number of rows and columns to be reduced.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit: if UPLO = 'U', the last NB columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of A; the elements above the diagonal with the array TAU, represent the unitary matrix Q as a

product of elementary reflectors; if UPLO = 'L', the first NB columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of A; the elements below the diagonal with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). If UPLO = 'U', E(n-nb:n-1) contains the superdiagonal elements of the last NB columns of the reduced matrix; if UPLO = 'L', E(1:nb) contains the subdiagonal elements of the first NB columns of the reduced matrix.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors, stored in TAU(n-nb:n-1) if UPLO = 'U', and in TAU(1:nb) if UPLO = 'L'. See Further Details.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (LDW, NB). The n-by-nb matrix W required to update the unreduced part of A.

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

Related Information

For this routine in other precisions, please see *clatrd*, *dlatrd* and *slatrd*.

4.17.774 zlatrs

zlatrs solves one of the triangular systems

```
A * x = s*b,  A**T * x = s*b,  or  A**H * x = s*b,
```

with scaling to prevent overflow. Here A is an upper or lower triangular matrix, A^T denotes the transpose of A, A^H denotes the conjugate transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine ZTRSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlatrs(UPLO, TRANS, DIAG, NORMIN, N, A, LDA, X, SCALE, CNORM,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zlatrs_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *x, double *scale, double *cnorm,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^H * x = s*b (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max (1, N).

X Input and output parameter.

X is COMPLEX*16

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

The scaling factor s for the triangular system A * x = s*b, A^T * x = s*b, or A^H * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is DOUBLE PRECISION

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatrs*, *dlatrs* and *slatrs*.

4.17.775 zlatrz

zlatrz factors the M-by-(M+L) complex upper trapezoidal matrix [A1 A2] = [A(1:M,1:M) A(1:M,N-L+1:N)] as (R 0) * Z by means of unitary transformations, where Z is an (M+L)-by-(M+L) unitary matrix and, R and A1 are M-by-M upper triangular matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlatrz(M, N, L, A, LDA, TAU, WORK)
```

C specification:

```
#include "armpl.h"

void zlatrz_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder vectors. N-M >= L >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements N-L+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (M). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (M) .

Related Information

For this routine in other precisions, please see *clatrz*, *dlatrz* and *slatrz*.

4.17.776 zlatsqr

SLATSQR computes a blocked Tall-Skinny QR factorization of an M-by-N matrix A, where M >= N: A = Q * R .

Syntax

Fortran specification:

```
use armpl_library

subroutine zlatsqr(M, N, MB, NB, A, LDA, T, LDT, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zlatsqr_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *mb, const armpl_int_t *nb,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              armpl_doublecomplex_t *t, const armpl_int_t *ldt,
              armpl_doublecomplex_t *work, const armpl_int_t *lwork,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. M >= N >= 0.

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. MB > N.

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. N >= NB >= 1.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the N-by-N upper triangular matrix R; the elements below the diagonal represent Q by the columns of blocked V (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array,. dimension (LDT, N * Number_of_row_blocks) where Number_of_row_blocks = CEIL((M-N)/(MB-N)) The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details below.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

(workspace) COMPLEX*16

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

The dimension of the array WORK. LWORK >= NB*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clatsqr*, *dlatsqr* and *slatsqr*.

4.17.777 zlauu2

`zlauu2` computes the product U * U^H or L^H * L, where the triangular factor U or L is stored in the upper or lower triangular part of the array A.

If UPLO = 'U' or 'u' then the upper triangle of the result is stored, overwriting the factor U in A. If UPLO = 'L' or 'l' then the lower triangle of the result is stored, overwriting the factor L in A.

This is the unblocked form of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlauu2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void zlauu2_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the triangular factor stored in the array A is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the triangular factor U or L. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the triangular factor U or L. On exit, if UPLO = 'U', the upper triangle of A is overwritten with the upper triangle of the product U * U^H ; if UPLO = 'L', the lower triangle of A is overwritten with the lower triangle of the product L^H * L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clauu2*, *dlauu2* and *slauu2*.

4.17.778 zlauum

`zlauum` computes the product U * U^H or L^H * L, where the triangular factor U or L is stored in the upper or lower triangular part of the array A.

If UPLO = 'U' or 'u' then the upper triangle of the result is stored, overwriting the factor U in A. If UPLO = 'L' or 'l' then the lower triangle of the result is stored, overwriting the factor L in A.

This is the blocked form of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zlauum(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void zlauum_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the triangular factor stored in the array A is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the triangular factor U or L. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the triangular factor U or L. On exit, if UPLO = 'U', the upper triangle of A is overwritten with the upper triangle of the product U * U^H ; if UPLO = 'L', the lower triangle of A is overwritten with the lower triangle of the product L^H * L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *clauum*, *dlauum* and *slauum*. It also exists with a native C interface as *LAPACKE_zlauum*.

4.17.779 zpbtf2

`zpbtf2` computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

```
A = U**H * U ,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix, U^H is the conjugate transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpbtf2(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void zpbtf2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

KD Input parameter.

`KD` is `INTEGER`

The number of super-diagonals of the matrix A if `UPLO` = 'U', or the number of sub-diagonals if `UPLO` = 'L'. `KD` >= 0.

AB Input and output parameter.

`AB` is `COMPLEX*16`

`AB` is an array, dimension (`LDAB`, `N`). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB

as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpbtf2*, *dpbtf2* and *spbtf2*.

4.17.780 zpotf2

zpotf2 computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

```
A = U**H * U ,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpotf2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void zpotf2_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *cpotf2*, *dpotf2* and *spotf2*.

4.17.781 zpstf2

zpstf2 computes the Cholesky factorization with complete pivoting of a complex Hermitian positive semidefinite matrix A.

The factorization has the form

```
P**T * A * P = U**H * U ,  if UPLO = 'U',
P**T * A * P = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector PIV.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpstf2(UPLO, N, A, LDA, PIV, RANK, TOL, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zpstf2_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *piv, armpl_int_t *rank,
             const double *tol, double *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization as above.

PIV Output parameter.

PIV is INTEGER array, dimension (N)

PIV is such that the nonzero entries are P(PIV(K), K) = 1.

RANK Output parameter.

RANK is INTEGER

The rank of A given by the number of steps the algorithm completed.

TOL Input parameter.

TOL is DOUBLE PRECISION

User defined tolerance. If TOL < 0, then N*U*MAX(A(K,K)) will be used. The algorithm terminates at the (K-1)st step if the pivot <= TOL.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N). Work space.

INFO Output parameter.

INFO is INTEGER

< 0: If INFO = -K, the K-th argument had an illegal value, = 0: algorithm completed successfully, and > 0: the matrix A is either rank deficient with computed rank as returned in RANK, or is not positive semidefinite. See Section 7 of LAPACK Working Note #161 for further information.

4.17.782 zptts2

zptts2 solves a tridiagonal system of the form

```
A * X = B
```

using the factorization A = U^H *D*U or A = L*D*L^H computed by ZPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine zptts2(IUPLO, N, NRHS, D, E, B, LDB)
```

C specification:

```
#include "armpl.h"

void zptts2_(const armpl_int_t *iuplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const double *d,
             const armpl_doublecomplex_t *e, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb);
```

Parameters

IUPLO Input parameter.

IUPLO is INTEGER

Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 1: A = U^H *D*U, E is the superdiagonal of U = 0: A = L*D*L^H , E is the subdiagonal of L

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization A = U^H *D*U or A = L*D*L^H .

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N-1). If IUPLO = 1, the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization A = U^H *D*U. If IUPLO = 0, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization A = L*D*L^H .

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Related Information

For this routine in other precisions, please see *cptts2*, *dptts2* and *sptts2*.

4.17.783 zsyconv

zsyconv converts A given by ZHETRF into L and D or vice-versa. Get nondiagonal elements of D (returned in workspace) and apply or reverse permutation done in TRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyconv(UPLO, WAY, N, A, LDA, IPIV, E, INFO)
```

C specification:

```
#include "armpl.h"

void zsyconv_(const char *uplo, const char *way, const armpl_int_t *n,
              armpl_doublecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_doublecomplex_t *e,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

E Output parameter.

E is COMPLEX*16

E is an array, dimension (N). E stores the supdiagonal/subdiagonal of the symmetric 1-by-1 or 2-by-2 block diagonal matrix D in LDLT.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyconv*, *dsyconv* and *ssyconv*. It also exists with a native C interface as *LAPACKE_zsyconv*.

4.17.784 zsyswapr

ZSYSWAPR applies an elementary permutation on the rows and the columns of a symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyswapr(UPLO, N, A, LDA, I1, I2)
```

C specification:

```
#include "armpl.h"

void zsyswapr_(const char *uplo, const armpl_int_t *n,
               armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_int_t *i1, const armpl_int_t *i2, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

I1 Input parameter.

I1 is INTEGER

Index of the first row to swap

I2 Input parameter.

I2 is INTEGER

Index of the second row to swap

Related Information

For this routine in other precisions, please see *csyswapr*, *dsyswapr* and *ssyswapr*. It also exists with a native C interface as *LAPACKE_zsyswapr*.

4.17.785 zsytf2

zsytf2 computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^T is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytf2(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zsytf2_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csytf2*, *dsytf2* and *ssytf2*.

4.17.786 zsytf2_rook

ZSYTF2_ROOK computes the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^T is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytf2_rook(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zsytf2_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_doublecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

> 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *csytf2_rook*, *dsytf2_rook* and *ssytf2_rook*.

4.17.787 ztfsm

Level 3 BLAS like routine for A in RFP Format.

ztfsm solves the matrix equation

```
op( A )*X = alpha*B  or  X*op( A ) = alpha*B
```

where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

```
op( A ) = A   or   op( A ) = A**H.
```

A is in Rectangular Full Packed (RFP) Format.

The matrix X is overwritten on B.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztfsm(TRANSR, SIDE, UPLO, TRANS, DIAG, M, N, ALPHA, A, B, LDB)
```

C specification:

```
#include "armpl.h"

void ztfsm_(const char *transr, const char *side, const char *uplo,
            const char *trans, const char *diag, const armpl_int_t *m,
            const armpl_int_t *n, const armpl_doublecomplex_t *alpha,
            const armpl_doublecomplex_t *a, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal Form of RFP A is stored; = 'C': The Conjugate-transpose Form of RFP A is stored.

SIDE Input parameter.

SIDE is CHARACTER*1

On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l' op(A)*X = alpha*B.

SIDE = 'R' or 'r' X*op(A) = alpha*B.

Unchanged on exit.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the RFP matrix A came from an upper or lower triangular matrix as follows: UPLO = 'U' or 'u' RFP A came from an upper triangular matrix UPLO = 'L' or 'l' RFP A came from a lower triangular matrix

Unchanged on exit.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANS = 'N' or 'n' op(A) = A.

TRANS = 'C' or 'c' op(A) = conjg(A').

Unchanged on exit.

DIAG Input parameter.

DIAG is CHARACTER*1

On entry, DIAG specifies whether or not RFP A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of B. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of B. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is COMPLEX*16

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (N*(N+1)/2). NT = N*(N+1)/2. On entry, the matrix A in RFP Format. RFP Format is described by TRANSR, UPLO and N as follows: If TRANSR='N' then RFP A is (0:N,0:K-1) when N is even; K=N/2. RFP A is (0:N-1,0:K) when N is odd; K=N/2. If TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the NT elements of upper packed A either in normal or conjugate-transpose Format. If UPLO = 'L' the RFP A contains the NT elements of lower packed A either in normal or conjugate-transpose Format. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and is N when is odd. See the Note below for more details. Unchanged on exit.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB Input parameter.

LDB is INTEGER

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m). Unchanged on exit.

Related Information

For this routine in other precisions, please see *ctfsm*, *dtfsm* and *stfsm*. It also exists with a native C interface as *LAPACKE_ztfsm*.

4.17.788 ztfttp

ztfttp copies a triangular matrix A from rectangular full packed format (TF) to standard packed format (TP).

Syntax

Fortran specification:

```
use armpl_library

subroutine ztfttp(TRANSR, UPLO, N, ARF, AP, INFO)
```

C specification:

```
#include "armpl.h"

void ztfttp_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *arf, armpl_doublecomplex_t *ap,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF is in Normal format; = 'C': ARF is in Conjugate-transpose format;

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ARF Input parameter.

ARF is COMPLEX*16

ARF is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

AP Output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctfttp*, *dtfttp* and *stfttp*. It also exists with a native C interface as *LAPACKE_ztfttp*.

4.17.789 ztfttr

ztfttr copies a triangular matrix A from rectangular full packed format (TF) to standard full format (TR).

Syntax

Fortran specification:

```
use armpl_library

subroutine ztfttr(TRANSR, UPLO, N, ARF, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void ztfttr_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *arf, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF is in Normal format; = 'C': ARF is in Conjugate-transpose format;

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ARF Input parameter.

ARF is COMPLEX*16

ARF is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

A Output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctfttr*, *dtfttr* and *stfttr*. It also exists with a native C interface as *LAPACKE_ztfttr*.

4.17.790 ztgex2

ztgex2 swaps adjacent diagonal 1 by 1 blocks (A11,B11) and (A22,B22) in an upper triangular matrix pair (A, B) by an unitary equivalence transformation.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)**H = Q(out) * A(out) * Z(out)**H
Q(in) * B(in) * Z(in)**H = Q(out) * B(out) * Z(out)**H
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ztgex2(WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, J1, INFO)
```

C specification:

```
#include "armpl.h"

void ztgex2_(const armpl_int_t *wantq, const armpl_int_t *wantz,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *q,
             const armpl_int_t *ldq, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, const armpl_int_t *j1,
             armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimensions (LDA, N). On entry, the matrix A in the pair (A, B). On exit, the updated matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimensions (LDB, N). On entry, the matrix B in the pair (A, B). On exit, the updated matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). If WANTQ = .TRUE, on entry, the unitary matrix Q. On exit, the updated matrix Q. Not referenced if WANTQ = .FALSE..

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If WANTZ = .TRUE, on entry, the unitary matrix Z. On exit, the updated matrix Z. Not referenced if WANTZ = .FALSE..

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

J1 Input parameter.

J1 is INTEGER

The index to the first block (A11, B11).

INFO Output parameter.

INFO is INTEGER

=0: Successful exit. =1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill- conditioned.

Related Information

For this routine in other precisions, please see *ctgex2*, *dtgex2* and *stgex2*.

4.17.791 ztgsy2

ztgsy2 solves the generalized Sylvester equation

```
A * R - L * B = scale * C                (1)
D * R - L * E = scale * F
```

using Level 1 and 2 BLAS, where R and L are unknown M-by-N matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size M-by-M, N-by-N and M-by-N, respectively. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation solving equation (1) corresponds to solve Zx = scale * b, where Z is defined as

```
Z = [ kron(In, A)  -kron(B**H, Im) ]             (2)
    [ kron(In, D)  -kron(E**H, Im) ],
```

Ik is the identity matrix of size k and X^H is the conjuguate transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y.

If TRANS = 'C', y in the conjugate transposed system Z^H *y = scale*b is solved for, which is equivalent to solve for R and L in

```
A**H * R  + D**H * L   = scale * C           (3)
R  * B**H + L  * E**H  = scale * -F
```

This case is used to compute an estimate of Dif[(A, D), (B, E)] = = sigma_min(Z) using reverse communicaton with ZLACON.

ztgsy2 also (IJOB >= 1) contributes to the computation in ZTGSYL of an upper bound on the separation between to matrix pairs. Then the input (A, D), (B, E) are sub-pencils of two matrix pairs in ZTGSYL.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztgsy2(TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD, E, LDE,
                  F, LDF, SCALE, RDSUM, RDSCAL, INFO)
```

C specification:

```
#include "armpl.h"

void ztgsy2_(const char *trans, const armpl_int_t *ijob, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, const armpl_doublecomplex_t *d,
             const armpl_int_t *ldd, const armpl_doublecomplex_t *e,
             const armpl_int_t *lde, armpl_doublecomplex_t *f,
             const armpl_int_t *ldf, double *scale, double *rdsum,
             double *rdscal, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N', solve the generalized Sylvester equation (1). = 'T': solve the 'transposed' system (3).

IJOB Input parameter.

IJOB is INTEGER

Specifies what kind of functionality to be performed. =0: solve (1) only. =1: A contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed. (look ahead strategy is used). =2: A contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed. (DGECON on sub-systems is used.) Not referenced if TRANS = 'T'.

M Input parameter.

M is INTEGER

On entry, M specifies the order of A and D, and the row dimension of C, F, R and L.

N Input parameter.

N is INTEGER

On entry, N specifies the order of B and E, and the column dimension of C, F, R and L.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, M). On entry, A contains an upper triangular matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the matrix A. LDA >= max(1, M).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, B contains an upper triangular matrix.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the matrix B. LDB >= max(1, N).

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, C contains the right-hand-side of the first matrix equation in (1). On exit, if IJOB = 0, C has been overwritten by the solution R.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the matrix C. LDC >= max(1, M).

D Input parameter.

D is COMPLEX*16

D is an array, dimension (LDD, M). On entry, D contains an upper triangular matrix.

LDD Input parameter.

LDD is INTEGER

The leading dimension of the matrix D. LDD >= max(1, M).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (LDE, N). On entry, E contains an upper triangular matrix.

LDE Input parameter.

LDE is INTEGER

The leading dimension of the matrix E. LDE >= max(1, N).

F Input and output parameter.

F is COMPLEX*16

F is an array, dimension (LDF, N). On entry, F contains the right-hand-side of the second matrix equation in (1). On exit, if IJOB = 0, F has been overwritten by the solution L.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the matrix F. LDF >= max(1, M).

SCALE Output parameter.

SCALE is DOUBLE PRECISION

On exit, 0 <= SCALE <= 1. If 0 < SCALE < 1, the solutions R and L (C and F on entry) will hold the solutions to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If SCALE = 0, R and L will hold the solutions to the homogeneous system with C = F = 0. Normally, SCALE = 1.

RDSUM Input and output parameter.

RDSUM is DOUBLE PRECISION

On entry, the sum of squares of computed contributions to the Dif-estimate under computation by ZTGSYL, where the scaling factor RDSCAL (see below) has been factored out. On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If TRANS = 'T' RDSUM is not touched. NOTE: RDSUM only makes sense when ZTGSY2 is called by ZTGSYL.

RDSCAL Input and output parameter.

RDSCAL is DOUBLE PRECISION

On entry, scaling factor used to prevent overflow in RDSUM. On exit, RDSCAL is updated w.r.t. the current contributions in RDSUM. If TRANS = 'T', RDSCAL is not touched. NOTE: RDSCAL only makes sense when ZTGSY2 is called by ZTGSYL.

INFO Output parameter.

INFO is INTEGER

On exit, if INFO is set to =0: Successful exit <0: If INFO = -i, input argument number i is illegal. >0: The matrix pairs (A, D) and (B, E) have common or very close eigenvalues.

Related Information

For this routine in other precisions, please see *ctgsy2*, *dtgsy2* and *stgsy2*.

4.17.792 ztplqt2

ztplqt2 computes a LQ a factorization of a complex "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztplqt2(M, N, L, A, LDA, B, LDB, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void ztplqt2_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *l, armpl_doublecomplex_t *a,
              const armpl_int_t *lda, armpl_doublecomplex_t *b,
              const armpl_int_t *ldb, armpl_doublecomplex_t *t,
              const armpl_int_t *ldt, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The total number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the lower trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, M). On entry, the lower triangular M-by-M matrix A. On exit, the elements on and below the diagonal of the array contain the lower triangular matrix L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first N-L columns are rectangular, and the last L columns are lower trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, M). The N-by-N upper triangular factor T of the block reflector. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, M)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctplqt2*, *dtplqt2* and *stplqt2*.

4.17.793 ztpqrt2

ztpqrt2 computes a QR factorization of a complex "triangular-pentagonal" matrix C, which is composed of a triangular block A and pentagonal block B, using the compact WY representation for Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztpqrt2(M, N, L, A, LDA, B, LDB, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void ztpqrt2_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *l, armpl_doublecomplex_t *a,
              const armpl_int_t *lda, armpl_doublecomplex_t *b,
              const armpl_int_t *ldb, armpl_doublecomplex_t *t,
              const armpl_int_t *ldt, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The total number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B, and the order of the triangular matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of rows of the upper trapezoidal part of B. MIN(M, N) >= L >= 0. See Further Details.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the upper triangular N-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the upper triangular matrix R.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the pentagonal M-by-N matrix B. The first M-L rows are rectangular, and the last L rows are upper trapezoidal. On exit, B contains the pentagonal matrix V. See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

T Output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). The N-by-N upper triangular factor T of the block reflector. See Further Details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpqrt2*, *dtpqrt2* and *stpqrt2*. It also exists with a native C interface as *LAPACKE_ztpqrt2*.

4.17.794 ztprfb

ztprfb applies a complex "triangular-pentagonal" block reflector H or its conjugate transpose H^H to a complex matrix C, which is composed of two blocks A and B, either from the left or right.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztprfb(SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV, T, LDT, A,
                  LDA, B, LDB, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void ztprfb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l,
             const armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             const armpl_doublecomplex_t *t, const armpl_int_t *ldt,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *work, const armpl_int_t *ldwork, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^H from the Left = 'R': apply H or H^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'C': apply H^H (Conjugate transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columns = 'R': Rows

M Input parameter.

M is INTEGER

The number of rows of the matrix B. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix B. N >= 0.

K Input parameter.

K is INTEGER

The order of the matrix T, i.e. the number of elementary reflectors whose product defines the block reflector. K >= 0.

L Input parameter.

L is INTEGER

The order of the trapezoidal part of V. K >= L >= 0. See Further Details.

V Input parameter.

V is COMPLEX*16

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, M) if STOREV = 'R' and SIDE = 'L' (LDV, N) if STOREV = 'R' and SIDE = 'R' The pentagonal matrix V, which contains the elementary reflectors H(1), H(2), . . . , H(K). See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C' and SIDE = 'L', LDV >= max(1, M); if STOREV = 'C' and SIDE = 'R', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

T Input parameter.

T is COMPLEX*16

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, N) if SIDE = 'L' or (LDA, K) if SIDE = 'R' On entry, the K-by-N or M-by-K matrix A. On exit, A is overwritten by the corresponding block of H*C or H^H *C or C*H or C*H^H . See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDC >= max(1, K); If SIDE = 'R', LDC >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the M-by-N matrix B. On exit, B is overwritten by the corresponding block of H*C or H^H *C or C*H or C*H^H . See Further Details.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension. (LDWORK, N) if SIDE = 'L', (LDWORK, K) if SIDE = 'R'.

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= K; if SIDE = 'R', LDWORK >= M.

Related Information

For this routine in other precisions, please see *ctprfb*, *dtprfb* and *stprfb*. It also exists with a native C interface as *LAPACKE_ztprfb*.

4.17.795 ztpttf

ztpttf copies a triangular matrix A from standard packed format (TP) to rectangular full packed format (TF).

Syntax

Fortran specification:

```
use armpl_library

subroutine ztpttf(TRANSR, UPLO, N, AP, ARF, INFO)
```

C specification:

```
#include "armpl.h"

void ztpttf_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *ap, armpl_doublecomplex_t *arf,
             armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF in Normal format is wanted; = 'C': ARF in Conjugate-transpose format is wanted.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

ARF Output parameter.

ARF is COMPLEX*16

ARF is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpttf*, *dtpttf* and *stpttf*. It also exists with a native C interface as *LAPACKE_ztpttf*.

4.17.796 ztpttr

ztpttr copies a triangular matrix A from standard packed format (TP) to standard full format (TR).

Syntax

Fortran specification:

```
use armpl_library

subroutine ztpttr(UPLO, N, AP, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void ztpttr_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *ap, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular. = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2),. On entry, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

A Output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On exit, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpttr*, *dtpttr* and *stpttr*. It also exists with a native C interface as *LAPACKE_ztpttr*.

4.17.797 ztrti2

ztrti2 computes the inverse of a complex upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrti2(UPLO, DIAG, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void ztrti2_(const char *uplo, const char *diag, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrti2*, *dtrti2* and *strti2*.

4.17.798 ztrttf

ztrttf copies a triangular matrix A from standard full format (TR) to rectangular full packed format (TF) .

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrttf(TRANSR, UPLO, N, A, LDA, ARF, INFO)
```

C specification:

```
#include "armpl.h"

void ztrttf_(const char *transr, const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *arf, armpl_int_t *info, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': ARF in Normal mode is wanted; = 'C': ARF in Conjugate Transpose mode is wanted;

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the matrix A. LDA >= max(1, N).

ARF Output parameter.

ARF is COMPLEX*16

ARF is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A stored in RFP format. For a further discussion see Notes below.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrttf*, *dtrttf* and *strttf*. It also exists with a native C interface as *LAPACKE_ztrttf*.

4.17.799 ztrttp

`ztrttp` copies a triangular matrix A from full format (TR) to standard packed format (TP).

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrttp(UPLO, N, A, LDA, AP, INFO)
```

C specification:

```
#include "armpl.h"

void ztrttp_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *ap, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

N Input parameter.

N is INTEGER

The order of the matrices AP and A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AP Output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2),. On exit, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.17.800 zunbdb1

`zunbdb1` simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                        [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                        [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. Q must be no larger than P, M-P, or M-Q. Routines ZUNBDB2, ZUNBDB3, and ZUNBDB4 handle cases in which Q is not the minimum dimension.

The unitary matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are Q-by-Q bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunbdb1(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunbdb1_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, armpl_doublecomplex_t *x11,
              const armpl_int_t *ldx11, armpl_doublecomplex_t *x21,
              const armpl_int_t *ldx21, double *theta, double *phi,
              armpl_doublecomplex_t *taup1, armpl_doublecomplex_t *taup2,
              armpl_doublecomplex_t *tauq1, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= MIN(P,M-P,M-Q).

X11 Input and output parameter.

X11 is COMPLEX*16

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is COMPLEX*16

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX*16

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX*16

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX*16

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cunbdb1*.

4.17.801 zunbdb2

zunbdb2 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                         [ B11 ]
[ X11 ]    [ P1 |    ] [  0  ]
[-----] = [----------] [-----] Q1**T .
[ X21 ]    [    | P2 ] [ B21 ]
                         [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. P must be no larger than M-P, Q, or M-Q. Routines ZUNBDB1, ZUNBDB3, and ZUNBDB4 handle cases in which P is not the minimum dimension.

The unitary matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are P-by-P bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunbdb2(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunbdb2_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, armpl_doublecomplex_t *x11,
              const armpl_int_t *ldx11, armpl_doublecomplex_t *x21,
              const armpl_int_t *ldx21, double *theta, double *phi,
              armpl_doublecomplex_t *taup1, armpl_doublecomplex_t *taup2,
              armpl_doublecomplex_t *tauq1, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= min(M-P, Q,M-Q).

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is COMPLEX*16

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is COMPLEX*16

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX*16

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX*16

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX*16

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cunbdb2*.

4.17.802 zunbdb3

zunbdb3 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                         [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                         [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. M-P must be no larger than P, Q, or M-Q. Routines ZUNBDB1, ZUNBDB2, and ZUNBDB4 handle cases in which M-P is not the minimum dimension.

The unitary matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are (M-P)-by-(M-P) bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunbdb3(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunbdb3_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, armpl_doublecomplex_t *x11,
              const armpl_int_t *ldx11, armpl_doublecomplex_t *x21,
              const armpl_int_t *ldx21, double *theta, double *phi,
              armpl_doublecomplex_t *taup1, armpl_doublecomplex_t *taup2,
              armpl_doublecomplex_t *tauq1, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M. M-P <= min(P, Q,M-Q).

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M.

X11 Input and output parameter.

X11 is COMPLEX*16

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is COMPLEX*16

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX*16

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX*16

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX*16

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cunbdb3*.

4.17.803 zunbdb4

zunbdb4 simultaneously bidiagonalizes the blocks of a tall and skinny matrix X with orthonomal columns:

```
                         [ B11 ]
[ X11 ]   [ P1 |    ] [  0  ]
[-----] = [---------] [-----] Q1**T .
[ X21 ]   [    | P2 ] [ B21 ]
                         [  0  ]
```

X11 is P-by-Q, and X21 is (M-P)-by-Q. M-Q must be no larger than P, M-P, or Q. Routines ZUNBDB1, ZUNBDB2, and ZUNBDB3 handle cases in which M-Q is not the minimum dimension.

The unitary matrices P1, P2, and Q1 are P-by-P, (M-P)-by-(M-P), and (M-Q)-by-(M-Q), respectively. They are represented implicitly by Householder vectors.

B11 and B12 are (M-Q)-by-(M-Q) bidiagonal matrices represented implicitly by angles THETA, PHI.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunbdb4(M, P, Q, X11, LDX11, X21, LDX21, THETA, PHI, TAUP1, TAUP2,
                   TAUQ1, PHANTOM, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunbdb4_(const armpl_int_t *m, const armpl_int_t *p,
              const armpl_int_t *q, armpl_doublecomplex_t *x11,
              const armpl_int_t *ldx11, armpl_doublecomplex_t *x21,
              const armpl_int_t *ldx21, double *theta, double *phi,
              armpl_doublecomplex_t *taup1, armpl_doublecomplex_t *taup2,
              armpl_doublecomplex_t *tauq1, armpl_doublecomplex_t *phantom,
              armpl_doublecomplex_t *work, const armpl_int_t *lwork,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows X11 plus the number of rows in X21.

P Input parameter.

P is INTEGER

The number of rows in X11. 0 <= P <= M.

Q Input parameter.

Q is INTEGER

The number of columns in X11 and X21. 0 <= Q <= M and M-Q <= min(P,M-P, Q).

X11 Input and output parameter.

X11 is COMPLEX*16

X11 is an array, dimension (LDX11, Q). On entry, the top block of the matrix X to be reduced. On exit, the columns of tril(X11) specify reflectors for P1 and the rows of triu(X11,1) specify reflectors for Q1.

LDX11 Input parameter.

LDX11 is INTEGER

The leading dimension of X11. LDX11 >= P.

X21 Input and output parameter.

X21 is COMPLEX*16

X21 is an array, dimension (LDX21, Q). On entry, the bottom block of the matrix X to be reduced. On exit, the columns of tril(X21) specify reflectors for P2.

LDX21 Input parameter.

LDX21 is INTEGER

The leading dimension of X21. LDX21 >= M-P.

THETA Output parameter.

THETA is DOUBLE PRECISION

THETA is an array, dimension (Q). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

PHI Output parameter.

PHI is DOUBLE PRECISION

PHI is an array, dimension (Q-1). The entries of the bidiagonal blocks B11, B21 are defined by THETA and PHI. See Further Details.

TAUP1 Output parameter.

TAUP1 is COMPLEX*16

TAUP1 is an array, dimension (P). The scalar factors of the elementary reflectors that define P1.

TAUP2 Output parameter.

TAUP2 is COMPLEX*16

TAUP2 is an array, dimension (M-P). The scalar factors of the elementary reflectors that define P2.

TAUQ1 Output parameter.

TAUQ1 is COMPLEX*16

TAUQ1 is an array, dimension (Q). The scalar factors of the elementary reflectors that define Q1.

PHANTOM Output parameter.

PHANTOM is COMPLEX*16

PHANTOM is an array, dimension (M). The routine computes an M-by-1 column vector Y that is orthogonal to the columns of [X11; X21]. PHANTOM(1:P) and PHANTOM(P+1:M) contain Householder vectors for Y(1:P) and Y(P+1:M), respectively.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= M-Q.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cunbdb4*.

4.17.804 zunbdb5

zunbdb5 orthogonalizes the column vector

```
X = [ X1 ]
    [ X2 ]
```

with respect to the columns of

```
Q = [ Q1 ] .
    [ Q2 ]
```

The columns of Q must be orthonormal.

If the projection is zero according to Kahan's "twice is enough" criterion, then some other vector from the orthogonal complement is returned. This vector is chosen in an arbitrary but deterministic way.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunbdb5(M1, M2, N, X1, INCX1, X2, INCX2, Q1, LDQ1, Q2, LDQ2, WORK,
                   LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunbdb5_(const armpl_int_t *m1, const armpl_int_t *m2,
              const armpl_int_t *n, armpl_doublecomplex_t *x1,
              const armpl_int_t *incx1, armpl_doublecomplex_t *x2,
              const armpl_int_t *incx2, armpl_doublecomplex_t *q1,
              const armpl_int_t *ldq1, armpl_doublecomplex_t *q2,
              const armpl_int_t *ldq2, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M1 Input parameter.

M1 is INTEGER

The dimension of X1 and the number of rows in Q1. 0 <= M1.

M2 Input parameter.

M2 is INTEGER

The dimension of X2 and the number of rows in Q2. 0 <= M2.

N Input parameter.

N is INTEGER

The number of columns in Q1 and Q2. 0 <= N.

X1 Input and output parameter.

X1 is COMPLEX*16

X1 is an array, dimension (M1). On entry, the top part of the vector to be orthogonalized. On exit, the top part of the projected vector.

INCX1 Input parameter.

INCX1 is INTEGER

Increment for entries of X1.

X2 Input and output parameter.

X2 is COMPLEX*16

X2 is an array, dimension (M2). On entry, the bottom part of the vector to be orthogonalized. On exit, the bottom part of the projected vector.

INCX2 Input parameter.

INCX2 is INTEGER

Increment for entries of X2.

Q1 Input parameter.

Q1 is COMPLEX*16

Q1 is an array, dimension (LDQ1, N). The top part of the orthonormal basis matrix.

LDQ1 Input parameter.

LDQ1 is INTEGER

The leading dimension of Q1. LDQ1 >= M1.

Q2 Input parameter.

Q2 is COMPLEX*16

Q2 is an array, dimension (LDQ2, N). The bottom part of the orthonormal basis matrix.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of Q2. LDQ2 >= M2.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cunbdb5*.

4.17.805 zunbdb6

zunbdb6 orthogonalizes the column vector

```
X = [ X1 ]
    [ X2 ]
```

with respect to the columns of

```
Q = [ Q1 ] .
    [ Q2 ]
```

The columns of Q must be orthonormal.

If the projection is zero according to Kahan's "twice is enough" criterion, then the zero vector is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunbdb6(M1, M2, N, X1, INCX1, X2, INCX2, Q1, LDQ1, Q2, LDQ2, WORK,
                   LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunbdb6_(const armpl_int_t *m1, const armpl_int_t *m2,
              const armpl_int_t *n, armpl_doublecomplex_t *x1,
              const armpl_int_t *incx1, armpl_doublecomplex_t *x2,
              const armpl_int_t *incx2, armpl_doublecomplex_t *q1,
              const armpl_int_t *ldq1, armpl_doublecomplex_t *q2,
              const armpl_int_t *ldq2, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

M1 Input parameter.

M1 is INTEGER

The dimension of X1 and the number of rows in Q1. 0 <= M1.

M2 Input parameter.

M2 is INTEGER

The dimension of X2 and the number of rows in Q2. 0 <= M2.

N Input parameter.

N is INTEGER

The number of columns in Q1 and Q2. 0 <= N.

X1 Input and output parameter.

X1 is COMPLEX*16

X1 is an array, dimension (M1). On entry, the top part of the vector to be orthogonalized. On exit, the top part of the projected vector.

INCX1 Input parameter.

INCX1 is INTEGER

Increment for entries of X1.

X2 Input and output parameter.

X2 is COMPLEX*16

X2 is an array, dimension (M2). On entry, the bottom part of the vector to be orthogonalized. On exit, the bottom part of the projected vector.

INCX2 Input parameter.

INCX2 is INTEGER

Increment for entries of X2.

Q1 Input parameter.

Q1 is COMPLEX*16

Q1 is an array, dimension (LDQ1, N). The top part of the orthonormal basis matrix.

LDQ1 Input parameter.

LDQ1 is INTEGER

The leading dimension of Q1. LDQ1 >= M1.

Q2 Input parameter.

Q2 is COMPLEX*16

Q2 is an array, dimension (LDQ2, N). The bottom part of the orthonormal basis matrix.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of Q2. LDQ2 >= M2.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cunbdb6*.

4.17.806 zung2l

zung2l generates an m by n complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

```
Q  =  H(k) . . . H(2) H(1)
```

as returned by ZGEQLF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zung2l(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zung2l_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGEQLF in the last k columns of its array argument A. On exit, the m-by-n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEQLF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *cung2l*.

4.17.807 zung2r

zung2r generates an m by n complex matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

```
Q  =  H(1) H(2) . . . H(k)
```

as returned by ZGEQRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zung2r(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zung2r_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,. . . ,k, as returned by ZGEQRF in the first k columns of its array argument A. On exit, the m by n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEQRF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *cung2r*.

4.17.808 zungl2

`zungl2` generates an m-by-n complex matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

```
Q  =  H(k)**H . . . H(2)**H H(1)**H
```

as returned by ZGELQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zungl2(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zungl2_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix Q. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix Q. `N` >= `M`.

K Input parameter.

`K` is `INTEGER`

The number of elementary reflectors whose product defines the matrix Q. `M` >= `K` >= 0.

A Input and output parameter.

`A` is `COMPLEX*16`

`A` is an array, dimension (`LDA`, `N`). On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGELQF in the first k rows of its array argument `A`. On exit, the m by n matrix Q.

LDA Input parameter.

`LDA` is `INTEGER`

The first dimension of the array `A`. `LDA` >= max(1, `M`).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGELQF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *cungl2*.

4.17.809 zungr2

zungr2 generates an m by n complex matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

```
Q  =  H(1)**H H(2)**H . . . H(k)**H
```

as returned by ZGERQF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zungr2(M, N, K, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zungr2_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *k,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix Q. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix Q. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGERQF in the last k rows of its array argument A. On exit, the m-by-n matrix Q.

LDA Input parameter.

LDA is INTEGER

The first dimension of the array A. LDA >= max(1, M).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGERQF.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument has an illegal value

Related Information

For this routine in other precisions, please see *cungr2*.

4.17.810 zunm2l

zunm2l overwrites the general complex m-by-n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**H* C  if SIDE = 'L' and TRANS = 'C', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**H if SIDE = 'R' and TRANS = 'C',
```

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(k) . . . H(2) H(1)
```

as returned by ZGEQLF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunm2l(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunm2l_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGEQLF in the last k columns of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEQLF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunm2l*.

4.17.811 zunm2r

zunm2r overwrites the general complex m-by-n matrix C with

```
Q * C  if SIDE = 'L' and TRANS = 'N', or

Q**H* C  if SIDE = 'L' and TRANS = 'C', or

C * Q  if SIDE = 'R' and TRANS = 'N', or

C * Q**H if SIDE = 'R' and TRANS = 'C',
```

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by ZGEQRF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunm2r(SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunm2r_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGEQRF in the first k columns of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEQRF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGELQF in the first k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGELQF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZGERQF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGERQF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

```

where Q is a complex unitary matrix defined as the product of k elementary reflectors

```
Q = H(1) H(2) . . . H(k)
```

as returned by ZTZRZF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

Syntax

Fortran specification:

```
use armpl_library

subroutine zunmr3(SIDE, TRANS, M, N, K, L, A, LDA, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunmr3_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *k, const armpl_int_t *l,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left = 'R': apply Q or Q^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by ZTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, K).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZTZRZF.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the m-by-n matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension. (N) if SIDE = 'L', (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

4.18 LAPACK utilities routines

4.18.1 chla_transtype

This subroutine translates from a BLAST-specified integer constant to the character string specifying a transposition operation.

CHLA_TRANSTYPE returns an CHARACTER*1. If CHLA_TRANSTYPE is 'X', then input is not an integer indicating a transposition operator. Otherwise CHLA_TRANSTYPE returns the constant value corresponding to TRANS.

Syntax

Fortran specification:

```
use armpl_library

character*1 function chla_transtype(TRANS)
```

C specification:

```
#include "armpl.h"

char chla_transtype_(const armpl_int_t *trans);
```

Related Information

4.18.2 dlabad

`dlabad` takes as input the values computed by DLAMCH for underflow and overflow, and returns the square root of each of these values if the log of LARGE is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by DLAMCH. This subroutine is needed because DLAMCH does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

Syntax

Fortran specification:

```
use armpl_library

subroutine dlabad(SMALL, LARGE)
```

C specification:

```
#include "armpl.h"

void dlabad_(double *small, double *large);
```

Parameters

SMALL Input and output parameter.

`SMALL` is `DOUBLE PRECISION`

On entry, the underflow threshold as computed by DLAMCH. On exit, if LOG10(`LARGE`) is sufficiently large, the square root of `SMALL`, otherwise unchanged.

LARGE Input and output parameter.

LARGE is DOUBLE PRECISION

On entry, the overflow threshold as computed by DLAMCH. On exit, if LOG10(LARGE) is sufficiently large, the square root of LARGE, otherwise unchanged.

Related Information

For this routine in other precisions, please see *slabad*.

4.18.3 ieeeck

ieeeck is called from the ILAENV to verify that Infinity and possibly NaN arithmetic is safe (i.e. will not trap).

Syntax

Fortran specification:

```
use armpl_library

integer function ieeeck(ISPEC, ZERO, ONE)
```

C specification:

```
#include "armpl.h"

armpl_int_t ieeeck_(const armpl_int_t *ispec, const float *zero,
                    const float *one);
```

Parameters

ISPEC Input parameter.

ISPEC is INTEGER

Specifies whether to test just for inifinity arithmetic or whether to test for infinity and NaN arithmetic. = 0: Verify infinity arithmetic only. = 1: Verify infinity and NaN arithmetic.

ZERO Input parameter.

ZERO is REAL

Must contain the value 0.0 This is passed to prevent the compiler from optimizing away this code.

ONE Input parameter.

ONE is REAL

Must contain the value 1.0 This is passed to prevent the compiler from optimizing away this code.

RETURN VALUE: INTEGER = 0: Arithmetic failed to produce the correct answers = 1: Arithmetic produced the correct answers

Related Information

4.18.4 iladiag

This subroutine translated from a character string specifying if a matrix has unit diagonal or not to the relevant BLAST-specified integer constant.

iladiag returns an INTEGER. If iladiag < 0, then the input is not a character indicating a unit or non-unit diagonal. Otherwise iladiag returns the constant value corresponding to DIAG.

Syntax

Fortran specification:

```
use armpl_library

integer function iladiag(DIAG)
```

C specification:

```
#include "armpl.h"

armpl_int_t iladiag_(const char *diag, ... );
```

Related Information

4.18.5 ilaenv

ilaenv is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See ISPEC for a description of the parameters.

ilaenv returns an INTEGER if ilaenv >= 0: ilaenv returns the value of the parameter specified by ISPEC if ilaenv < 0: if ilaenv = -k, the k-th argument had an illegal value.

This version provides a set of parameters which should give good, but not optimal, performance on many of the currently available computers. Users are encouraged to modify this subroutine to set the tuning parameters for their particular machine using the option and problem size information in the arguments.

This routine will not function correctly if it is converted to all lower case. Converting it to all upper case is allowed.

Syntax

Fortran specification:

```
use armpl_library

integer function ilaenv(ISPEC, NAME, OPTS, N1, N2, N3, N4)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilaenv_(const armpl_int_t *ispec, const char *name,
                    const char *opts, const armpl_int_t *n1,
                    const armpl_int_t *n2, const armpl_int_t *n3,
                    const armpl_int_t *n4, ... );
```

Parameters

ISPEC Input parameter.

ISPEC is INTEGER

Specifies the parameter to be returned as the value of ILAENV. = 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance. = 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used. =

3: the crossover point (in a block routine, for N less than this value, an unblocked routine should be used) = 4: the number of shifts, used in the nonsymmetric eigenvalue routines (DEPRECATED) = 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least k by m, where k is given by ILAENV(2,...) and m by ILAENV(5,...) = 6: the crossover point for the SVD (when reducing an m by n matrix to bidiagonal form, if max(m,n)/min(m,n) exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form.) = 7: the number of processors = 8: the crossover point for the multishift QR method for nonsymmetric eigenvalue problems (DEPRECATED) = 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by xGELSD and xGESDD) =10: ieee NaN arithmetic can be trusted not to trap =11: infinity arithmetic can be trusted not to trap 12 <= `ISPEC` <= 16: xHSEQR or related subroutines, see IPARMQ for detailed explanation

NAME Input parameter.

`NAME` is CHARACTER*(*)

The name of the calling subroutine, in either upper case or lower case.

OPTS Input parameter.

`OPTS` is CHARACTER*(*)

The character options to the subroutine `NAME`, concatenated into a single character string. For example, UPLO = 'U', TRANS = 'T', and DIAG = 'N' for a triangular routine would be specified as `OPTS` = 'UTN'.

N1 Input parameter.

`N1` is `INTEGER`

N2 Input parameter.

`N2` is `INTEGER`

N3 Input parameter.

`N3` is `INTEGER`

N4 Input parameter.

`N4` is `INTEGER`

Problem dimensions for the subroutine NAME; these may not all be required.

Related Information

4.18.6 ilaprec

This subroutine translated from a character string specifying an intermediate precision to the relevant BLAST-specified integer constant.

`ilaprec` returns an INTEGER. If `ilaprec` < 0, then the input is not a character indicating a supported intermediate precision. Otherwise `ilaprec` returns the constant value corresponding to PREC.

Syntax

Fortran specification:

```
use armpl_library

integer function ilaprec(PREC)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilaprec_(const char *prec, ... );
```

Related Information

4.18.7 ilatrans

This subroutine translates from a character string specifying a transposition operation to the relevant BLAST-specified integer constant.

ILATRANS returns an INTEGER. If ILATRANS < 0, then the input is not a character indicating a transposition operator. Otherwise ILATRANS returns the constant value corresponding to TRANS.

Syntax

Fortran specification:

```
use armpl_library

integer function ilatrans(TRANS)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilatrans_(const char *trans, ... );
```

Related Information

4.18.8 ilauplo

This subroutine translated from a character string specifying a upper- or lower-triangular matrix to the relevant BLAST-specified integer constant.

`ilauplo` returns an INTEGER. If `ilauplo` < 0, then the input is not a character indicating an upper- or lower-triangular matrix. Otherwise `ilauplo` returns the constant value corresponding to UPLO.

Syntax

Fortran specification:

```
use armpl_library

integer function ilauplo(UPLO)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilauplo_(const char *uplo, ... );
```

Related Information

4.18.9 iparmq

```
This program sets problem and machine dependent parameters
     useful for xHSEQR and related subroutines for eigenvalue
     problems. It is called whenever
     IPARMQ is called with 12 <= ISPEC <= 16
```

Syntax

Fortran specification:

```
use armpl_library

integer function iparmq(ISPEC, NAME, OPTS, N, ILO, IHI, LWORK)
```

C specification:

```
#include "armpl.h"

armpl_int_t iparmq_(const armpl_int_t *ispec, const char *name,
                    const char *opts, const armpl_int_t *n,
                    const armpl_int_t *ilo, const armpl_int_t *ihi,
                    const armpl_int_t *lwork, ... );
```

Parameters

ISPEC Input parameter.

ISPEC is INTEGER

ISPEC specifies which tunable parameter IPARMQ should return.

ISPEC=12: (INMIN) Matrices of order nmin or less are sent directly to xLAHQR, the implicit double shift QR algorithm. NMIN must be at least 11.

ISPEC=13: (INWIN) Size of the deflation window. This is best set greater than or equal to the number of simultaneous shifts NS. Larger matrices benefit from larger deflation windows.

ISPEC=14: (INIBL) Determines when to stop nibbling and invest in an (expensive) multi-shift QR sweep. If the aggressive early deflation subroutine finds LD converged eigenvalues from an order NW deflation window and LD.GT.(NW*NIBBLE)/100, then the next QR sweep is skipped and early deflation is applied immediately to the remaining active diagonal block. Setting IPARMQ(ISPEC=14) = 0 causes TTQRE to skip a multi-shift QR sweep whenever early deflation finds a converged eigenvalue. Setting IPARMQ(ISPEC=14) greater than or equal to 100 prevents TTQRE from skipping a multi-shift QR sweep.

ISPEC=15: (NSHFTS) The number of simultaneous shifts in a multi-shift QR iteration.

ISPEC=16: (IACC22) IPARMQ is set to 0, 1 or 2 with the following meanings. 0: During the multi-shift QR/QZ sweep, blocked eigenvalue reordering, blocked Hessenberg-triangular reduction, reflections and/or rotations are not accumulated when updating the far-from-diagonal matrix entries. 1: During the multi-shift QR/QZ sweep, blocked eigenvalue reordering, blocked Hessenberg-triangular reduction, reflections and/or rotations are accumulated, and matrix-matrix multiplication is used to update the far-from-diagonal matrix entries. 2: During the multi-shift QR/QZ sweep, blocked eigenvalue reordering, blocked Hessenberg-triangular reduction, reflections and/or rotations are accumulated, and 2-by-2 block structure is exploited during matrix-matrix multiplies. (If xTRMM is slower than xGEMM, then IPARMQ(ISPEC=16)=1 may be more efficient than IPARMQ(ISPEC=16)=2 despite the greater level of arithmetic work implied by the latter choice.)

NAME Input parameter.

NAME is character string

Name of the calling subroutine

OPTS Input parameter.

OPTS is character string

This is a concatenation of the string arguments to TTQRE.

N Input parameter.

N is INTEGER

N is the order of the Hessenberg matrix H.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N.

LWORK Input parameter.

LWORK is INTEGER

The amount of workspace available.

Related Information

4.18.10 slabad

slabad takes as input the values computed by SLAMCH for underflow and overflow, and returns the square root of each of these values if the log of LARGE is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by SLAMCH. This subroutine is needed because SLAMCH does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

Syntax

Fortran specification:

```
use armpl_library

subroutine slabad(SMALL, LARGE)
```

C specification:

```
#include "armpl.h"

void slabad_(float *small, float *large);
```

Parameters

SMALL Input and output parameter.

SMALL is REAL

On entry, the underflow threshold as computed by SLAMCH. On exit, if LOG10(LARGE) is sufficiently large, the square root of SMALL, otherwise unchanged.

LARGE Input and output parameter.

LARGE is REAL

On entry, the overflow threshold as computed by SLAMCH. On exit, if LOG10(LARGE) is sufficiently large, the square root of LARGE, otherwise unchanged.

Related Information

For this routine in other precisions, please see *dlabad*.

4.18.11 xerbla

`xerbla` is an error handler for the LAPACK routines. It is called by an LAPACK routine if an input parameter has an invalid value. A message is printed and execution stops.

Installers may consider modifying the STOP statement in order to call system-specific exception-handling facilities.

Syntax

Fortran specification:

```
use armpl_library

subroutine xerbla(SRNAME, INFO)
```

C specification:

```
#include "armpl.h"

void xerbla_(const char *srname, const armpl_int_t *info, ... );
```

Parameters

SRNAME Input parameter.

SRNAME is CHARACTER*(*)

The name of the routine which called XERBLA.

INFO Input parameter.

INFO is INTEGER

The position of the invalid parameter in the parameter list of the calling routine.

Related Information

It also exists with a native C interface as *cblas_xerbla*.

4.18.12 xerbla_array

XERBLA_ARRAY assists other languages in calling XERBLA, the LAPACK and BLAS error handler. Rather than taking a Fortran string argument as the function's name, XERBLA_ARRAY takes an array of single characters along with the array's length. XERBLA_ARRAY then copies up to 32 characters of that array into a Fortran string and passes that to XERBLA. If called with a non-positive SRNAME_LEN, XERBLA_ARRAY will call XERBLA with a string of all blank characters.

Say some macro or other device makes XERBLA_ARRAY available to C99 by a name lapack_xerbla and with a common Fortran calling convention. Then a C99 program could invoke XERBLA via:

```
{
  int flen = strlen(__func__);
  lapack_xerbla(__func__, &amp;flen, &amp;info);
}
```

Providing XERBLA_ARRAY is not necessary for intercepting LAPACK errors. XERBLA_ARRAY calls XERBLA.

Syntax

Fortran specification:

```
use armpl_library

subroutine xerbla_array(SRNAME_ARRAY, SRNAME_LEN, INFO)
```

C specification:

```
#include "armpl.h"

void xerbla_array_(const char *srname_array, const armpl_int_t *srname_len,
                   const armpl_int_t *info, ... );
```

Parameters

SRNAME_ARRAY Input parameter.

SRNAME_ARRAY is CHARACTER(1) array, dimension (SRNAME_LEN)

The name of the routine which called XERBLA_ARRAY.

SRNAME_LEN Input parameter.

SRNAME_LEN is INTEGER

The length of the name in SRNAME_ARRAY.

INFO Input parameter.

INFO is INTEGER

The position of the invalid parameter in the parameter list of the calling routine.

4.19 LAPACKE - C interfaces for LAPACK functions

4.19.1 LAPACKE_cbbcsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cbbcsd(armpl_int_t matrix_layout, char jobu1, char jobu2,
                           char jobv1t, char jobv2t, char trans,
                           armpl_int_t m, armpl_int_t p, armpl_int_t q,
                           float *theta, float *phi,
                           armpl_singlecomplex_t *u1, armpl_int_t ldu1,
                           armpl_singlecomplex_t *u2, armpl_int_t ldu2,
                           armpl_singlecomplex_t *v1t, armpl_int_t ldv1t,
                           armpl_singlecomplex_t *v2t, armpl_int_t ldv2t,
                           float *b11d, float *b11e, float *b12d, float *b12e,
                           float *b21d, float *b21e, float *b22d,
                           float *b22e);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbbcsd*, *LAPACKE_dbbcsd*, *LAPACKE_sbbcsd* and *LAPACKE_zbbcsd*. It also exists with a native Fortran interface as *cbbcsd*.

4.19.2 LAPACKE_cbbcsd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cbbcsd_work(armpl_int_t matrix_layout, char jobu1,
                                char jobu2, char jobv1t, char jobv2t,
                                char trans, armpl_int_t m, armpl_int_t p,
                                armpl_int_t q, float *theta, float *phi,
                                armpl_singlecomplex_t *u1, armpl_int_t ldu1,
                                armpl_singlecomplex_t *u2, armpl_int_t ldu2,
                                armpl_singlecomplex_t *v1t, armpl_int_t ldv1t,
                                armpl_singlecomplex_t *v2t, armpl_int_t ldv2t,
                                float *b11d, float *b11e, float *b12d,
                                float *b12e, float *b21d, float *b21e,
                                float *b22d, float *b22e, float *rwork,
                                armpl_int_t lrwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbbcsd_work*, *LAPACKE_dbbcsd_work*, *LAPACKE_sbbcsd_work* and *LAPACKE_zbbcsd_work*.

4.19.3 LAPACKE_cbdsqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cbdsqr(armpl_int_t matrix_layout, char uplo,
                           armpl_int_t n, armpl_int_t ncvt, armpl_int_t nru,
                           armpl_int_t ncc, float *d, float *e,
```

(continues on next page)

(continued from previous page)

```
                                armpl_singlecomplex_t *vt, armpl_int_t ldvt,
                                armpl_singlecomplex_t *u, armpl_int_t ldu,
                                armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbdsqr*, *LAPACKE_dbdsqr*, *LAPACKE_sbdsqr* and *LAPACKE_zbdsqr*. It also exists with a native Fortran interface as *cbdsqr*.

4.19.4 LAPACKE_cbdsqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cbdsqr_work(armpl_int_t matrix_layout, char uplo,
                                armpl_int_t n, armpl_int_t ncvt,
                                armpl_int_t nru, armpl_int_t ncc, float *d,
                                float *e, armpl_singlecomplex_t *vt,
                                armpl_int_t ldvt, armpl_singlecomplex_t *u,
                                armpl_int_t ldu, armpl_singlecomplex_t *c,
                                armpl_int_t ldc, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cbdsqr_work*, *LAPACKE_dbdsqr_work*, *LAPACKE_sbdsqr_work* and *LAPACKE_zbdsqr_work*.

4.19.5 LAPACKE_cgbbrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbbrd(armpl_int_t matrix_layout, char vect,
                           armpl_int_t m, armpl_int_t n, armpl_int_t ncc,
                           armpl_int_t kl, armpl_int_t ku,
                           armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           float *d, float *e, armpl_singlecomplex_t *q,
                           armpl_int_t ldq, armpl_singlecomplex_t *pt,
                           armpl_int_t ldpt, armpl_singlecomplex_t *c,
                           armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbbrd*, *LAPACKE_dgbbrd*, *LAPACKE_sgbbrd* and *LAPACKE_zgbbrd*. It also exists with a native Fortran interface as *cgbbrd*.

4.19.6 LAPACKE_cgbbrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbbrd_work(armpl_int_t matrix_layout, char vect,
                                armpl_int_t m, armpl_int_t n, armpl_int_t ncc,
                                armpl_int_t kl, armpl_int_t ku,
                                armpl_singlecomplex_t *ab, armpl_int_t ldab,
                                float *d, float *e, armpl_singlecomplex_t *q,
                                armpl_int_t ldq, armpl_singlecomplex_t *pt,
                                armpl_int_t ldpt, armpl_singlecomplex_t *c,
                                armpl_int_t ldc, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbbrd_work*, *LAPACKE_dgbbrd_work*, *LAPACKE_sgbbrd_work* and *LAPACKE_zgbbrd_work*.

4.19.7 LAPACKE_cgbcon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbcon(armpl_int_t matrix_layout, char norm,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           const armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           const armpl_int_t *ipiv, float anorm,
                           float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbcon*, *LAPACKE_dgbcon*, *LAPACKE_sgbcon* and *LAPACKE_zgbcon*. It also exists with a native Fortran interface as *cgbcon*.

4.19.8 LAPACKE_cgbcon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbcon_work(armpl_int_t matrix_layout, char norm,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, const armpl_int_t *ipiv,
                                float anorm, float *rcond,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbcon_work*, *LAPACKE_dgbcon_work*, *LAPACKE_sgbcon_work* and *LAPACKE_zgbcon_work*.

4.19.9 LAPACKE_cgbequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbequ(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           const armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           float *r, float *c, float *rowcnd, float *colcnd,
                           float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequ*, *LAPACKE_dgbequ*, *LAPACKE_sgbequ* and *LAPACKE_zgbequ*. It also exists with a native Fortran interface as *cgbequ*.

4.19.10 LAPACKE_cgbequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbequ_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, float *r, float *c,
                                float *rowcnd, float *colcnd, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequ_work*, *LAPACKE_dgbequ_work*, *LAPACKE_sgbequ_work* and *LAPACKE_zgbequ_work*.

4.19.11 LAPACKE_cgbequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbequb(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            const armpl_singlecomplex_t *ab, armpl_int_t ldab,
                            float *r, float *c, float *rowcnd, float *colcnd,
                            float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbequb*, *LAPACKE_dgbequb*, *LAPACKE_sgbequb* and *LAPACKE_zgbequb*. It also exists with a native Fortran interface as *cgbequb*.

4.19.12 LAPACKE_cgbequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbequb_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku,
                                 const armpl_singlecomplex_t *ab,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldab, float *r, float *c,
                                float *rowcnd, float *colcnd, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.13 LAPACKE_cgbrfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbrfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, const armpl_singlecomplex_t *ab,
                           armpl_int_t ldab, const armpl_singlecomplex_t *afb,
                           armpl_int_t ldafb, const armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbrfs*, *LAPACKE_dgbrfs*, *LAPACKE_sgbrfs* and *LAPACKE_zgbrfs*. It also exists with a native Fortran interface as *cgbrfs*.

4.19.14 LAPACKE_cgbrfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbrfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab,
                                const armpl_singlecomplex_t *afb,
                                armpl_int_t ldafb, const armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbrfs_work*, *LAPACKE_dgbrfs_work*, *LAPACKE_sgbrfs_work* and *LAPACKE_zgbrfs_work*.

4.19.15 LAPACKE_cgbrfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbrfsx(armpl_int_t matrix_layout, char trans, char equed,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            armpl_int_t nrhs, const armpl_singlecomplex_t *ab,
                            armpl_int_t ldab,
                            const armpl_singlecomplex_t *afb,
                            armpl_int_t ldafb, const armpl_int_t *ipiv,
                            const float *r, const float *c,
                            const armpl_singlecomplex_t *b, armpl_int_t ldb,
                            armpl_singlecomplex_t *x, armpl_int_t ldx,
                            float *rcond, float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbrfsx*, *LAPACKE_dgbrfsx*, *LAPACKE_sgbrfsx* and *LAPACKE_zgbrfsx*. It also exists with a native Fortran interface as *cgbrfsx*.

4.19.16 LAPACKE_cgbrfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbrfsx_work(armpl_int_t matrix_layout, char trans,
                                 char equed, armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku, armpl_int_t nrhs,
                                 const armpl_singlecomplex_t *ab,
                                 armpl_int_t ldab,
                                 const armpl_singlecomplex_t *afb,
                                 armpl_int_t ldafb, const armpl_int_t *ipiv,
                                 const float *r, const float *c,
                                 const armpl_singlecomplex_t *b,
                                 armpl_int_t ldb, armpl_singlecomplex_t *x,
                                 armpl_int_t ldx, float *rcond, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, armpl_singlecomplex_t *work,
                                 float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbrfsx_work*, *LAPACKE_dgbrfsx_work*, *LAPACKE_sgbrfsx_work* and *LAPACKE_zgbrfsx_work*.

4.19.17 LAPACKE_cgbsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbsv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t kl, armpl_int_t ku, armpl_int_t nrhs,
                          armpl_singlecomplex_t *ab, armpl_int_t ldab,
                          armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                          armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsv*, *LAPACKE_dgbsv*, *LAPACKE_sgbsv* and *LAPACKE_zgbsv*. It also exists with a native Fortran interface as *cgbsv*.

4.19.18 LAPACKE_cgbsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbsv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t kl, armpl_int_t ku,
                               armpl_int_t nrhs, armpl_singlecomplex_t *ab,
                               armpl_int_t ldab, armpl_int_t *ipiv,
                               armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsv_work*, *LAPACKE_dgbsv_work*, *LAPACKE_sgbsv_work* and *LAPACKE_zgbsv_work*.

4.19.19 LAPACKE_cgbsvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbsvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, armpl_singlecomplex_t *ab,
                           armpl_int_t ldab, armpl_singlecomplex_t *afb,
                           armpl_int_t ldafb, armpl_int_t *ipiv, char *equed,
                           float *r, float *c, armpl_singlecomplex_t *b,
                           armpl_int_t ldb, armpl_singlecomplex_t *x,
                           armpl_int_t ldx, float *rcond, float *ferr,
                           float *berr, float *rpivot);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvx*, *LAPACKE_dgbsvx*, *LAPACKE_sgbsvx* and *LAPACKE_zgbsvx*. It also exists with a native Fortran interface as *cgbsvx*.

4.19.20 LAPACKE_cgbsvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbsvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t kl,
                                armpl_int_t ku, armpl_int_t nrhs,
                                armpl_singlecomplex_t *ab, armpl_int_t ldab,
                                armpl_singlecomplex_t *afb, armpl_int_t ldafb,
                                armpl_int_t *ipiv, char *equed, float *r,
                                float *c, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvx_work*, *LAPACKE_dgbsvx_work*, *LAPACKE_sgbsvx_work* and *LAPACKE_zgbsvx_work*.

4.19.21 LAPACKE_cgbsvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbsvxx(armpl_int_t matrix_layout, char fact, char trans,
                            armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                            armpl_int_t nrhs, armpl_singlecomplex_t *ab,
                            armpl_int_t ldab, armpl_singlecomplex_t *afb,
                            armpl_int_t ldafb, armpl_int_t *ipiv, char *equed,
                            float *r, float *c, armpl_singlecomplex_t *b,
                            armpl_int_t ldb, armpl_singlecomplex_t *x,
                            armpl_int_t ldx, float *rcond, float *rpvgrw,
                            float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbsvxx*, *LAPACKE_dgbsvxx*, *LAPACKE_sgbsvxx* and *LAPACKE_zgbsvxx*. It also exists with a native Fortran interface as *cgbsvxx*.

4.19.22 LAPACKE_cgbsvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbsvxx_work(armpl_int_t matrix_layout, char fact,
                                 char trans, armpl_int_t n, armpl_int_t kl,
                                 armpl_int_t ku, armpl_int_t nrhs,

                                float *err_bnds_comp, armpl_int_t nparams,
                                float *params, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.23 LAPACKE_cgbtrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbtrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_singlecomplex_t *ab, armpl_int_t ldab,
                           armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrf*, *LAPACKE_dgbtrf*, *LAPACKE_sgbtrf* and *LAPACKE_zgbtrf*. It also exists with a native Fortran interface as *cgbtrf*.

4.19.24 LAPACKE_cgbtrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbtrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                armpl_singlecomplex_t *ab, armpl_int_t ldab,
                                armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.25 LAPACKE_cgbtrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbtrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                           armpl_int_t nrhs, const armpl_singlecomplex_t *ab,
                           armpl_int_t ldab, const armpl_int_t *ipiv,
                           armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrs*, *LAPACKE_dgbtrs*, *LAPACKE_sgbtrs* and *LAPACKE_zgbtrs*. It also exists with a native Fortran interface as *cgbtrs*.

4.19.26 LAPACKE_cgbtrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgbtrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t kl, armpl_int_t ku,
                                armpl_int_t nrhs,
                                const armpl_singlecomplex_t *ab,
                                armpl_int_t ldab, const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgbtrs_work*, *LAPACKE_dgbtrs_work*, *LAPACKE_sgbtrs_work* and *LAPACKE_zgbtrs_work*.

4.19.27 LAPACKE_cgebak

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgebak(armpl_int_t matrix_layout, char job, char side,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           const float *scale, armpl_int_t m,
                           armpl_singlecomplex_t *v, armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebak*, *LAPACKE_dgebak*, *LAPACKE_sgebak* and *LAPACKE_zgebak*. It also exists with a native Fortran interface as *cgebak*.

4.19.28 LAPACKE_cgebak_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgebak_work(armpl_int_t matrix_layout, char job,
                                char side, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, const float *scale,
                                armpl_int_t m, armpl_singlecomplex_t *v,
                                armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebak_work*, *LAPACKE_dgebak_work*, *LAPACKE_sgebak_work* and *LAPACKE_zgebak_work*.

4.19.29 LAPACKE_cgebal

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgebal(armpl_int_t matrix_layout, char job, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_int_t *ilo, armpl_int_t *ihi, float *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebal*, *LAPACKE_dgebal*, *LAPACKE_sgebal* and *LAPACKE_zgebal*. It also exists with a native Fortran interface as *cgebal*.

4.19.30 LAPACKE_cgebal_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgebal_work(armpl_int_t matrix_layout, char job,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ilo,
                                armpl_int_t *ihi, float *scale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebal_work*, *LAPACKE_dgebal_work*, *LAPACKE_sgebal_work* and *LAPACKE_zgebal_work*.

4.19.31 LAPACKE_cgebrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgebrd(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, float *d, float *e,
                           armpl_singlecomplex_t *tauq,
                           armpl_singlecomplex_t *taup);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.32 LAPACKE_cgebrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgebrd_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, float *d, float *e,
                                armpl_singlecomplex_t *tauq,
                                armpl_singlecomplex_t *taup,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgebrd_work*, *LAPACKE_dgebrd_work*, *LAPACKE_sgebrd_work* and *LAPACKE_zgebrd_work*.

4.19.33 LAPACKE_cgecon

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgecon(armpl_int_t matrix_layout, char norm,
                           armpl_int_t n, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, float anorm, float *rcond);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgecon*, *LAPACKE_dgecon*, *LAPACKE_sgecon* and *LAPACKE_zgecon*. It also exists with a native Fortran interface as *cgecon*.

4.19.34 LAPACKE_cgecon_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgecon_work(armpl_int_t matrix_layout, char norm,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda, float anorm, float *rcond,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgecon_work*, *LAPACKE_dgecon_work*, *LAPACKE_sgecon_work* and *LAPACKE_zgecon_work*.

4.19.35 LAPACKE_cgeequ

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeequ(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, const armpl_singlecomplex_t *a,
                           armpl_int_t lda, float *r, float *c, float *rowcnd,
                           float *colcnd, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequ*, *LAPACKE_dgeequ*, *LAPACKE_sgeequ* and *LAPACKE_zgeequ*. It also exists with a native Fortran interface as *cgeequ*.

4.19.36 LAPACKE_cgeequ_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeequ_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, const armpl_singlecomplex_t *a,
                                armpl_int_t lda, float *r, float *c,
                                float *rowcnd, float *colcnd, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequ_work*, *LAPACKE_dgeequ_work*, *LAPACKE_sgeequ_work* and *LAPACKE_zgeequ_work*.

4.19.37 LAPACKE_cgeequb

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeequb(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, const armpl_singlecomplex_t *a,
                            armpl_int_t lda, float *r, float *c,
                            float *rowcnd, float *colcnd, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequb*, *LAPACKE_dgeequb*, *LAPACKE_sgeequb* and *LAPACKE_zgeequb*. It also exists with a native Fortran interface as *cgeequb*.

4.19.38 LAPACKE_cgeequb_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeequb_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n,
                                 const armpl_singlecomplex_t *a,
                                 armpl_int_t lda, float *r, float *c,
                                 float *rowcnd, float *colcnd, float *amax);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeequb_work*, *LAPACKE_dgeequb_work*, *LAPACKE_sgeequb_work* and *LAPACKE_zgeequb_work*.

4.19.39 LAPACKE_cgees

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgees(armpl_int_t matrix_layout, char jobvs, char sort,
                          LAPACK_C_SELECT1 select, armpl_int_t n,
                          armpl_singlecomplex_t *a, armpl_int_t lda,
                          armpl_int_t *sdim, armpl_singlecomplex_t *w,
                          armpl_singlecomplex_t *vs, armpl_int_t ldvs);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgees*, *LAPACKE_dgees*, *LAPACKE_sgees* and *LAPACKE_zgees*. It also exists with a native Fortran interface as *cgees*.

4.19.40 LAPACKE_cgees_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgees_work(armpl_int_t matrix_layout, char jobvs,
                               char sort, LAPACK_C_SELECT1 select,
                               armpl_int_t n, armpl_singlecomplex_t *a,
                               armpl_int_t lda, armpl_int_t *sdim,
                               armpl_singlecomplex_t *w,
                               armpl_singlecomplex_t *vs, armpl_int_t ldvs,
                               armpl_singlecomplex_t *work, armpl_int_t lwork,
                               float *rwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgees_work*, *LAPACKE_dgees_work*, *LAPACKE_sgees_work* and *LAPACKE_zgees_work*.

4.19.41 LAPACKE_cgeesx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeesx(armpl_int_t matrix_layout, char jobvs, char sort,
                           LAPACK_C_SELECT1 select, char sense, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_int_t *sdim, armpl_singlecomplex_t *w,
                           armpl_singlecomplex_t *vs, armpl_int_t ldvs,
                           float *rconde, float *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeesx*, *LAPACKE_dgeesx*, *LAPACKE_sgeesx* and *LAPACKE_zgeesx*. It also exists with a native Fortran interface as *cgeesx*.

4.19.42 LAPACKE_cgeesx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeesx_work(armpl_int_t matrix_layout, char jobvs,
                                char sort, LAPACK_C_SELECT1 select,
                                char sense, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_int_t *sdim, armpl_singlecomplex_t *w,
                                armpl_singlecomplex_t *vs, armpl_int_t ldvs,
                                float *rconde, float *rcondv,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeesx_work*, *LAPACKE_dgeesx_work*, *LAPACKE_sgeesx_work* and *LAPACKE_zgeesx_work*.

4.19.43 LAPACKE_cgeev

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeev(armpl_int_t matrix_layout, char jobvl, char jobvr,
                          armpl_int_t n, armpl_singlecomplex_t *a,
                          armpl_int_t lda, armpl_singlecomplex_t *w,
                          armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                          armpl_singlecomplex_t *vr, armpl_int_t ldvr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeev*, *LAPACKE_dgeev*, *LAPACKE_sgeev* and *LAPACKE_zgeev*. It also exists with a native Fortran interface as *cgeev*.

4.19.44 LAPACKE_cgeev_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeev_work(armpl_int_t matrix_layout, char jobvl,
                               char jobvr, armpl_int_t n,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               armpl_singlecomplex_t *w,
                               armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                               armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                               armpl_singlecomplex_t *work, armpl_int_t lwork,
                               float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeev_work*, *LAPACKE_dgeev_work*, *LAPACKE_sgeev_work* and *LAPACKE_zgeev_work*.

4.19.45 LAPACKE_cgeevx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeevx(armpl_int_t matrix_layout, char balanc, char jobvl,
                           char jobvr, char sense, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *w,
                           armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                           armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                           armpl_int_t *ilo, armpl_int_t *ihi, float *scale,
                           float *abnrm, float *rconde, float *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeevx*, *LAPACKE_dgeevx*, *LAPACKE_sgeevx* and *LAPACKE_zgeevx*. It also exists with a native Fortran interface as *cgeevx*.

4.19.46 LAPACKE_cgeevx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeevx_work(armpl_int_t matrix_layout, char balanc,
                                char jobvl, char jobvr, char sense,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *w,
                                armpl_singlecomplex_t *vl, armpl_int_t ldvl,
                                armpl_singlecomplex_t *vr, armpl_int_t ldvr,
                                armpl_int_t *ilo, armpl_int_t *ihi,
                                float *scale, float *abnrm, float *rconde,
                                float *rcondv, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeevx_work*, *LAPACKE_dgeevx_work*, *LAPACKE_sgeevx_work* and *LAPACKE_zgeevx_work*.

4.19.47 LAPACKE_cgehrd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgehrd(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_int_t ilo, armpl_int_t ihi,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgehrd*, *LAPACKE_dgehrd*, *LAPACKE_sgehrd* and *LAPACKE_zgehrd*. It also exists with a native Fortran interface as *cgehrd*.

4.19.48 LAPACKE_cgehrd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgehrd_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_int_t ilo, armpl_int_t ihi,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgehrd_work*, *LAPACKE_dgehrd_work*, *LAPACKE_sgehrd_work* and *LAPACKE_zgehrd_work*.

4.19.49 LAPACKE_cgejsv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgejsv(armpl_int_t matrix_layout, char joba, char jobu,
                           char jobv, char jobr, char jobt, char jobp,
                           armpl_int_t m, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           float *sva, armpl_singlecomplex_t *u,
                           armpl_int_t ldu, armpl_singlecomplex_t *v,
                           armpl_int_t ldv, float *stat, armpl_int_t *istat);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgejsv*, *LAPACKE_dgejsv*, *LAPACKE_sgejsv* and *LAPACKE_zgejsv*. It also exists with a native Fortran interface as *cgejsv*.

4.19.50 LAPACKE_cgejsv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgejsv_work(armpl_int_t matrix_layout, char joba,
                                char jobu, char jobv, char jobr, char jobt,
                                char jobp, armpl_int_t m, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                float *sva, armpl_singlecomplex_t *u,
                                armpl_int_t ldu, armpl_singlecomplex_t *v,
                                armpl_int_t ldv, armpl_singlecomplex_t *cwork,
                                armpl_int_t lwork, float *work,
                                armpl_int_t lrwork, armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgejsv_work*, *LAPACKE_dgejsv_work*, *LAPACKE_sgejsv_work* and *LAPACKE_zgejsv_work*.

4.19.51 LAPACKE_cgelq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelq(armpl_int_t matrix_layout, armpl_int_t m,
                          armpl_int_t n, armpl_singlecomplex_t *a,
                          armpl_int_t lda, armpl_singlecomplex_t *t,
                          armpl_int_t tsize);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq*, *LAPACKE_dgelq*, *LAPACKE_sgelq* and *LAPACKE_zgelq*. It also exists with a native Fortran interface as *cgelq*.

4.19.52 LAPACKE_cgelq2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelq2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq2*, *LAPACKE_dgelq2*, *LAPACKE_sgelq2* and *LAPACKE_zgelq2*. It also exists with a native Fortran interface as *cgelq2*.

4.19.53 LAPACKE_cgelq2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelq2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq2_work*, *LAPACKE_dgelq2_work*, *LAPACKE_sgelq2_work* and *LAPACKE_zgelq2_work*.

4.19.54 LAPACKE_cgelq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelq_work(armpl_int_t matrix_layout, armpl_int_t m,
                               armpl_int_t n, armpl_singlecomplex_t *a,
                               armpl_int_t lda, armpl_singlecomplex_t *t,
                               armpl_int_t tsize, armpl_singlecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelq_work*, *LAPACKE_dgelq_work*, *LAPACKE_sgelq_work* and *LAPACKE_zgelq_work*.

4.19.55 LAPACKE_cgelqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelqf*, *LAPACKE_dgelqf*, *LAPACKE_sgelqf* and *LAPACKE_zgelqf*. It also exists with a native Fortran interface as *cgelqf*.

4.19.56 LAPACKE_cgelqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelqf_work*, *LAPACKE_dgelqf_work*, *LAPACKE_sgelqf_work* and *LAPACKE_zgelqf_work*.

4.19.57 LAPACKE_cgels

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgels(armpl_int_t matrix_layout, char trans,
                          armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                          armpl_singlecomplex_t *a, armpl_int_t lda,
                          armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgels*, *LAPACKE_dgels*, *LAPACKE_sgels* and *LAPACKE_zgels*. It also exists with a native Fortran interface as *cgels*.

4.19.58 LAPACKE_cgels_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgels_work(armpl_int_t matrix_layout, char trans,
                               armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               armpl_singlecomplex_t *b, armpl_int_t ldb,
                               armpl_singlecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.59 LAPACKE_cgelsd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelsd(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           float *s, float rcond, armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsd*, *LAPACKE_dgelsd*, *LAPACKE_sgelsd* and *LAPACKE_zgelsd*. It also exists with a native Fortran interface as *cgelsd*.

4.19.60 LAPACKE_cgelsd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelsd_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
```

(continues on next page)

(continued from previous page)

```
                                    float *s, float rcond, armpl_int_t *rank,
                                    armpl_singlecomplex_t *work,
                                    armpl_int_t lwork, float *rwork,
                                    armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.61 LAPACKE_cgelss

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelss(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           float *s, float rcond, armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelss*, *LAPACKE_dgelss*, *LAPACKE_sgelss* and *LAPACKE_zgelss*. It also exists with a native Fortran interface as *cgelss*.

4.19.62 LAPACKE_cgelss_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelss_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                float *s, float rcond, armpl_int_t *rank,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelss_work*, *LAPACKE_dgelss_work*, *LAPACKE_sgelss_work* and *LAPACKE_zgelss_work*.

4.19.63 LAPACKE_cgelsy

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelsy(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_int_t *jpvt, float rcond,
                           armpl_int_t *rank);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsy*, *LAPACKE_dgelsy*, *LAPACKE_sgelsy* and *LAPACKE_zgelsy*. It also exists with a native Fortran interface as *cgelsy*.

4.19.64 LAPACKE_cgelsy_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgelsy_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nrhs,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_int_t *jpvt, float rcond,
                                armpl_int_t *rank,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgelsy_work*, *LAPACKE_dgelsy_work*, *LAPACKE_sgelsy_work* and *LAPACKE_zgelsy_work*.

4.19.65 LAPACKE_cgemlq

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgemlq(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *t, armpl_int_t tsize,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemlq*, *LAPACKE_dgemlq*, *LAPACKE_sgemlq* and *LAPACKE_zgemlq*. It also exists with a native Fortran interface as *cgemlq*.

4.19.66 LAPACKE_cgemlq_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgemlq_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *t,
                                armpl_int_t tsize, armpl_singlecomplex_t *c,
                                armpl_int_t ldc, armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemlq_work*, *LAPACKE_dgemlq_work*, *LAPACKE_sgemlq_work* and *LAPACKE_zgemlq_work*.

4.19.67 LAPACKE_cgemqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgemqr(armpl_int_t matrix_layout, char side, char trans,
                           armpl_int_t m, armpl_int_t n, armpl_int_t k,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *t, armpl_int_t tsize,
                           armpl_singlecomplex_t *c, armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqr*, *LAPACKE_dgemqr*, *LAPACKE_sgemqr* and *LAPACKE_zgemqr*. It also exists with a native Fortran interface as *cgemqr*.

4.19.68 LAPACKE_cgemqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgemqr_work(armpl_int_t matrix_layout, char side,
                                char trans, armpl_int_t m, armpl_int_t n,
                                armpl_int_t k, const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *t,
                                armpl_int_t tsize, armpl_singlecomplex_t *c,
                                armpl_int_t ldc, armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqr_work*, *LAPACKE_dgemqr_work*, *LAPACKE_sgemqr_work* and *LAPACKE_zgemqr_work*.

4.19.69 LAPACKE_cgemqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgemqrt(armpl_int_t matrix_layout, char side, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t k,
                            armpl_int_t nb, const armpl_singlecomplex_t *v,
                            armpl_int_t ldv, const armpl_singlecomplex_t *t,
                            armpl_int_t ldt, armpl_singlecomplex_t *c,
                            armpl_int_t ldc);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqrt*, *LAPACKE_dgemqrt*, *LAPACKE_sgemqrt* and *LAPACKE_zgemqrt*. It also exists with a native Fortran interface as *cgemqrt*.

4.19.70 LAPACKE_cgemqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgemqrt_work(armpl_int_t matrix_layout, char side,
                                 char trans, armpl_int_t m, armpl_int_t n,
                                 armpl_int_t k, armpl_int_t nb,
                                 const armpl_singlecomplex_t *v,
                                 armpl_int_t ldv,
                                 const armpl_singlecomplex_t *t,
                                 armpl_int_t ldt, armpl_singlecomplex_t *c,
                                 armpl_int_t ldc,
                                 armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgemqrt_work*, *LAPACKE_dgemqrt_work*, *LAPACKE_sgemqrt_work* and *LAPACKE_zgemqrt_work*.

4.19.71 LAPACKE_cgeqlf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqlf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqlf*, *LAPACKE_dgeqlf*, *LAPACKE_sgeqlf* and *LAPACKE_zgeqlf*. It also exists with a native Fortran interface as *cgeqlf*.

4.19.72 LAPACKE_cgeqlf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqlf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.73 LAPACKE_cgeqp3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqp3(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *jpvt,
                           armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqp3*, *LAPACKE_dgeqp3*, *LAPACKE_sgeqp3* and *LAPACKE_zgeqp3*. It also exists with a native Fortran interface as *cgeqp3*.

4.19.74 LAPACKE_cgeqp3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqp3_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *jpvt,
                                armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqp3_work*, *LAPACKE_dgeqp3_work*, *LAPACKE_sgeqp3_work* and *LAPACKE_zgeqp3_work*.

4.19.75 LAPACKE_cgeqpf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqpf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *jpvt,
                           armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.76 LAPACKE_cgeqpf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqpf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *jpvt,
                                armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqpf_work*, *LAPACKE_dgeqpf_work*, *LAPACKE_sgeqpf_work* and *LAPACKE_zgeqpf_work*.

4.19.77 LAPACKE_cgeqr

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqr(armpl_int_t matrix_layout, armpl_int_t m,
                          armpl_int_t n, armpl_singlecomplex_t *a,
                          armpl_int_t lda, armpl_singlecomplex_t *t,
                          armpl_int_t tsize);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr*, *LAPACKE_dgeqr*, *LAPACKE_sgeqr* and *LAPACKE_zgeqr*. It also exists with a native Fortran interface as *cgeqr*.

4.19.78 LAPACKE_cgeqr2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqr2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr2*, *LAPACKE_dgeqr2*, *LAPACKE_sgeqr2* and *LAPACKE_zgeqr2*. It also exists with a native Fortran interface as *cgeqr2*.

4.19.79 LAPACKE_cgeqr2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqr2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr2_work*, *LAPACKE_dgeqr2_work*, *LAPACKE_sgeqr2_work* and *LAPACKE_zgeqr2_work*.

4.19.80 LAPACKE_cgeqr_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqr_work(armpl_int_t matrix_layout, armpl_int_t m,
                               armpl_int_t n, armpl_singlecomplex_t *a,
                               armpl_int_t lda, armpl_singlecomplex_t *t,
                               armpl_int_t tsize, armpl_singlecomplex_t *work,
                               armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqr_work*, *LAPACKE_dgeqr_work*, *LAPACKE_sgeqr_work* and *LAPACKE_zgeqr_work*.

4.19.81 LAPACKE_cgeqrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrf*, *LAPACKE_dgeqrf*, *LAPACKE_sgeqrf* and *LAPACKE_zgeqrf*. It also exists with a native Fortran interface as *cgeqrf*.

4.19.82 LAPACKE_cgeqrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrf_work*, *LAPACKE_dgeqrf_work*, *LAPACKE_sgeqrf_work* and *LAPACKE_zgeqrf_work*.

4.19.83 LAPACKE_cgeqrfp

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrfp(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_singlecomplex_t *a,
                            armpl_int_t lda, armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrfp*, *LAPACKE_dgeqrfp*, *LAPACKE_sgeqrfp* and *LAPACKE_zgeqrfp*. It also exists with a native Fortran interface as *cgeqrfp*.

4.19.84 LAPACKE_cgeqrfp_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrfp_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, armpl_singlecomplex_t *tau,
                                 armpl_singlecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrfp_work*, *LAPACKE_dgeqrfp_work*, *LAPACKE_sgeqrfp_work* and *LAPACKE_zgeqrfp_work*.

4.19.85 LAPACKE_cgeqrt

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrt(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_int_t nb,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *t, armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt*, *LAPACKE_dgeqrt*, *LAPACKE_sgeqrt* and *LAPACKE_zgeqrt*. It also exists with a native Fortran interface as *cgeqrt*.

4.19.86 LAPACKE_cgeqrt2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrt2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_singlecomplex_t *a,
                            armpl_int_t lda, armpl_singlecomplex_t *t,
                            armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt2*, *LAPACKE_dgeqrt2*, *LAPACKE_sgeqrt2* and *LAPACKE_zgeqrt2*. It also exists with a native Fortran interface as *cgeqrt2*.

4.19.87 LAPACKE_cgeqrt2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrt2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, armpl_singlecomplex_t *t,
                                 armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt2_work*, *LAPACKE_dgeqrt2_work*, *LAPACKE_sgeqrt2_work* and *LAPACKE_zgeqrt2_work*.

4.19.88 LAPACKE_cgeqrt3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrt3(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_singlecomplex_t *a,
                            armpl_int_t lda, armpl_singlecomplex_t *t,
                            armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt3*, *LAPACKE_dgeqrt3*, *LAPACKE_sgeqrt3* and *LAPACKE_zgeqrt3*. It also exists with a native Fortran interface as *cgeqrt3*.

4.19.89 LAPACKE_cgeqrt3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrt3_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, armpl_singlecomplex_t *t,
                                 armpl_int_t ldt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt3_work*, *LAPACKE_dgeqrt3_work*, *LAPACKE_sgeqrt3_work* and *LAPACKE_zgeqrt3_work*.

4.19.90 LAPACKE_cgeqrt_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgeqrt_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_int_t nb,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *t, armpl_int_t ldt,
                                armpl_singlecomplex_t *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgeqrt_work*, *LAPACKE_dgeqrt_work*, *LAPACKE_sgeqrt_work* and *LAPACKE_zgeqrt_work*.

4.19.91 LAPACKE_cgerfs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgerfs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_singlecomplex_t *af, armpl_int_t ldaf,
                           const armpl_int_t *ipiv,
                           const armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *ferr, float *berr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfs*, *LAPACKE_dgerfs*, *LAPACKE_sgerfs* and *LAPACKE_zgerfs*. It also exists with a native Fortran interface as *cgerfs*.

4.19.92 LAPACKE_cgerfs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgerfs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda,
                                const armpl_singlecomplex_t *af,
                                armpl_int_t ldaf, const armpl_int_t *ipiv,
                                const armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *ferr, float *berr,
                                armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfs_work*, *LAPACKE_dgerfs_work*, *LAPACKE_sgerfs_work* and *LAPACKE_zgerfs_work*.

4.19.93 LAPACKE_cgerfsx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgerfsx(armpl_int_t matrix_layout, char trans, char equed,
                            armpl_int_t n, armpl_int_t nrhs,
                            const armpl_singlecomplex_t *a, armpl_int_t lda,
                            const armpl_singlecomplex_t *af, armpl_int_t ldaf,
                            const armpl_int_t *ipiv, const float *r,
                            const float *c, const armpl_singlecomplex_t *b,
                            armpl_int_t ldb, armpl_singlecomplex_t *x,
                            armpl_int_t ldx, float *rcond, float *berr,
                            armpl_int_t n_err_bnds, float *err_bnds_norm,
                            float *err_bnds_comp, armpl_int_t nparams,
                            float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfsx*, *LAPACKE_dgerfsx*, *LAPACKE_sgerfsx* and *LAPACKE_zgerfsx*. It also exists with a native Fortran interface as *cgerfsx*.

4.19.94 LAPACKE_cgerfsx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgerfsx_work(armpl_int_t matrix_layout, char trans,
                                 char equed, armpl_int_t n, armpl_int_t nrhs,
                                 const armpl_singlecomplex_t *a,
                                 armpl_int_t lda,
                                 const armpl_singlecomplex_t *af,
                                 armpl_int_t ldaf, const armpl_int_t *ipiv,
                                 const float *r, const float *c,
                                 const armpl_singlecomplex_t *b,
                                 armpl_int_t ldb, armpl_singlecomplex_t *x,
                                 armpl_int_t ldx, float *rcond, float *berr,
                                 armpl_int_t n_err_bnds, float *err_bnds_norm,
                                 float *err_bnds_comp, armpl_int_t nparams,
                                 float *params, armpl_singlecomplex_t *work,
                                 float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerfsx_work*, *LAPACKE_dgerfsx_work*, *LAPACKE_sgerfsx_work* and *LAPACKE_zgerfsx_work*.

4.19.95 LAPACKE_cgerqf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgerqf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *tau);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerqf*, *LAPACKE_dgerqf*, *LAPACKE_sgerqf* and *LAPACKE_zgerqf*. It also exists with a native Fortran interface as *cgerqf*.

4.19.96 LAPACKE_cgerqf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgerqf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *tau,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgerqf_work*, *LAPACKE_dgerqf_work*, *LAPACKE_sgerqf_work* and *LAPACKE_zgerqf_work*.

4.19.97 LAPACKE_cgesdd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesdd(armpl_int_t matrix_layout, char jobz,
                           armpl_int_t m, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           float *s, armpl_singlecomplex_t *u,
                           armpl_int_t ldu, armpl_singlecomplex_t *vt,
                           armpl_int_t ldvt);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesdd*, *LAPACKE_dgesdd*, *LAPACKE_sgesdd* and *LAPACKE_zgesdd*. It also exists with a native Fortran interface as *cgesdd*.

4.19.98 LAPACKE_cgesdd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesdd_work(armpl_int_t matrix_layout, char jobz,
                                armpl_int_t m, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                float *s, armpl_singlecomplex_t *u,
                                armpl_int_t ldu, armpl_singlecomplex_t *vt,
                                armpl_int_t ldvt, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesdd_work*, *LAPACKE_dgesdd_work*, *LAPACKE_sgesdd_work* and *LAPACKE_zgesdd_work*.

4.19.99 LAPACKE_cgesv

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesv(armpl_int_t matrix_layout, armpl_int_t n,
                          armpl_int_t nrhs, armpl_singlecomplex_t *a,
                          armpl_int_t lda, armpl_int_t *ipiv,
                          armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesv*, *LAPACKE_dgesv*, *LAPACKE_sgesv* and *LAPACKE_zgesv*. It also exists with a native Fortran interface as *cgesv*.

4.19.100 LAPACKE_cgesv_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesv_work(armpl_int_t matrix_layout, armpl_int_t n,
                               armpl_int_t nrhs, armpl_singlecomplex_t *a,
                               armpl_int_t lda, armpl_int_t *ipiv,
                               armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesv_work*, *LAPACKE_dgesv_work*, *LAPACKE_sgesv_work* and *LAPACKE_zgesv_work*.

4.19.101 LAPACKE_cgesvd

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvd(armpl_int_t matrix_layout, char jobu, char jobvt,
                           armpl_int_t m, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           float *s, armpl_singlecomplex_t *u,
                           armpl_int_t ldu, armpl_singlecomplex_t *vt,
                           armpl_int_t ldvt, float *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvd*, *LAPACKE_dgesvd*, *LAPACKE_sgesvd* and *LAPACKE_zgesvd*. It also exists with a native Fortran interface as *cgesvd*.

4.19.102 LAPACKE_cgesvd_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvd_work(armpl_int_t matrix_layout, char jobu,
                                char jobvt, armpl_int_t m, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                float *s, armpl_singlecomplex_t *u,
                                armpl_int_t ldu, armpl_singlecomplex_t *vt,
                                armpl_int_t ldvt, armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvd_work*, *LAPACKE_dgesvd_work*, *LAPACKE_sgesvd_work* and *LAPACKE_zgesvd_work*.

4.19.103 LAPACKE_cgesvdx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvdx(armpl_int_t matrix_layout, char jobu, char jobvt,
                            char range, armpl_int_t m, armpl_int_t n,
```

(continues on next page)

(continued from previous page)

```
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                float vl, float vu, armpl_int_t il,
                                armpl_int_t iu, armpl_int_t *ns, float *s,
                                armpl_singlecomplex_t *u, armpl_int_t ldu,
                                armpl_singlecomplex_t *vt, armpl_int_t ldvt,
                                armpl_int_t *superb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvdx*, *LAPACKE_dgesvdx*, *LAPACKE_sgesvdx* and *LAPACKE_zgesvdx*. It also exists with a native Fortran interface as *cgesvdx*.

4.19.104 LAPACKE_cgesvdx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvdx_work(armpl_int_t matrix_layout, char jobu,
                                 char jobvt, char range, armpl_int_t m,
                                 armpl_int_t n, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, float vl, float vu,
                                 armpl_int_t il, armpl_int_t iu,
                                 armpl_int_t *ns, float *s,
                                 armpl_singlecomplex_t *u, armpl_int_t ldu,
                                 armpl_singlecomplex_t *vt, armpl_int_t ldvt,
                                 armpl_singlecomplex_t *work,
                                 armpl_int_t lwork, float *rwork,
                                 armpl_int_t *iwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvdx_work*, *LAPACKE_dgesvdx_work*, *LAPACKE_sgesvdx_work* and *LAPACKE_zgesvdx_work*.

4.19.105 LAPACKE_cgesvj

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvj(armpl_int_t matrix_layout, char joba, char jobu,
                           char jobv, armpl_int_t m, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           float *sva, armpl_int_t mv,
                           armpl_singlecomplex_t *v, armpl_int_t ldv,
                           float *stat);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvj*, *LAPACKE_dgesvj*, *LAPACKE_sgesvj* and *LAPACKE_zgesvj*. It also exists with a native Fortran interface as *cgesvj*.

4.19.106 LAPACKE_cgesvj_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvj_work(armpl_int_t matrix_layout, char joba,
                                char jobu, char jobv, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, float *sva, armpl_int_t mv,
                                armpl_singlecomplex_t *v, armpl_int_t ldv,
                                armpl_singlecomplex_t *cwork,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t lrwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvj_work*, *LAPACKE_dgesvj_work*, *LAPACKE_sgesvj_work* and *LAPACKE_zgesvj_work*.

4.19.107 LAPACKE_cgesvx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvx(armpl_int_t matrix_layout, char fact, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *af, armpl_int_t ldaf,
                           armpl_int_t *ipiv, char *equed, float *r, float *c,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_singlecomplex_t *x, armpl_int_t ldx,
                           float *rcond, float *ferr, float *berr,
                           float *rpivot);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvx*, *LAPACKE_dgesvx*, *LAPACKE_sgesvx* and *LAPACKE_zgesvx*. It also exists with a native Fortran interface as *cgesvx*.

4.19.108 LAPACKE_cgesvx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvx_work(armpl_int_t matrix_layout, char fact,
                                char trans, armpl_int_t n, armpl_int_t nrhs,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *af, armpl_int_t ldaf,
                                armpl_int_t *ipiv, char *equed, float *r,
                                float *c, armpl_singlecomplex_t *b,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldb, armpl_singlecomplex_t *x,
                                armpl_int_t ldx, float *rcond, float *ferr,
                                float *berr, armpl_singlecomplex_t *work,
                                float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.109 LAPACKE_cgesvxx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvxx(armpl_int_t matrix_layout, char fact, char trans,
                            armpl_int_t n, armpl_int_t nrhs,
                            armpl_singlecomplex_t *a, armpl_int_t lda,
                            armpl_singlecomplex_t *af, armpl_int_t ldaf,
                            armpl_int_t *ipiv, char *equed, float *r,
                            float *c, armpl_singlecomplex_t *b,
                            armpl_int_t ldb, armpl_singlecomplex_t *x,
                            armpl_int_t ldx, float *rcond, float *rpvgrw,
                            float *berr, armpl_int_t n_err_bnds,
                            float *err_bnds_norm, float *err_bnds_comp,
                            armpl_int_t nparams, float *params);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvxx*, *LAPACKE_dgesvxx*, *LAPACKE_sgesvxx* and *LAPACKE_zgesvxx*. It also exists with a native Fortran interface as *cgesvxx*.

4.19.110 LAPACKE_cgesvxx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgesvxx_work(armpl_int_t matrix_layout, char fact,
                                 char trans, armpl_int_t n, armpl_int_t nrhs,
                                 armpl_singlecomplex_t *a, armpl_int_t lda,
                                 armpl_singlecomplex_t *af, armpl_int_t ldaf,
                                 armpl_int_t *ipiv, char *equed, float *r,
                                 float *c, armpl_singlecomplex_t *b,
                                 armpl_int_t ldb, armpl_singlecomplex_t *x,
                                 armpl_int_t ldx, float *rcond, float *rpvgrw,
                                 float *berr, armpl_int_t n_err_bnds,
                                 float *err_bnds_norm, float *err_bnds_comp,
                                 armpl_int_t nparams, float *params,
                                 armpl_singlecomplex_t *work, float *rwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgesvxx_work*, *LAPACKE_dgesvxx_work*, *LAPACKE_sgesvxx_work* and *LAPACKE_zgesvxx_work*.

4.19.111 LAPACKE_cgetf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetf2(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetf2*, *LAPACKE_dgetf2*, *LAPACKE_sgetf2* and *LAPACKE_zgetf2*. It also exists with a native Fortran interface as *cgetf2*.

4.19.112 LAPACKE_cgetf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetf2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetf2_work*, *LAPACKE_dgetf2_work*, *LAPACKE_sgetf2_work* and *LAPACKE_zgetf2_work*.

4.19.113 LAPACKE_cgetrf

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetrf(armpl_int_t matrix_layout, armpl_int_t m,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf*, *LAPACKE_dgetrf*, *LAPACKE_sgetrf* and *LAPACKE_zgetrf*. It also exists with a native Fortran interface as *cgetrf*.

4.19.114 LAPACKE_cgetrf2

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetrf2(armpl_int_t matrix_layout, armpl_int_t m,
                            armpl_int_t n, armpl_singlecomplex_t *a,
                            armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf2*, *LAPACKE_dgetrf2*, *LAPACKE_sgetrf2* and *LAPACKE_zgetrf2*. It also exists with a native Fortran interface as *cgetrf2*.

4.19.115 LAPACKE_cgetrf2_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetrf2_work(armpl_int_t matrix_layout, armpl_int_t m,
                                 armpl_int_t n, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf2_work*, *LAPACKE_dgetrf2_work*, *LAPACKE_sgetrf2_work* and *LAPACKE_zgetrf2_work*.

4.19.116 LAPACKE_cgetrf_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetrf_work(armpl_int_t matrix_layout, armpl_int_t m,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrf_work*, *LAPACKE_dgetrf_work*, *LAPACKE_sgetrf_work* and *LAPACKE_zgetrf_work*.

4.19.117 LAPACKE_cgetri

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetri(armpl_int_t matrix_layout, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_int_t *ipiv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetri*, *LAPACKE_dgetri*, *LAPACKE_sgetri* and *LAPACKE_zgetri*. It also exists with a native Fortran interface as *cgetri*.

4.19.118 LAPACKE_cgetri_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetri_work(armpl_int_t matrix_layout, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetri_work*, *LAPACKE_dgetri_work*, *LAPACKE_sgetri_work* and *LAPACKE_zgetri_work*.

4.19.119 LAPACKE_cgetrs

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetrs(armpl_int_t matrix_layout, char trans,
                           armpl_int_t n, armpl_int_t nrhs,
                           const armpl_singlecomplex_t *a, armpl_int_t lda,
                           const armpl_int_t *ipiv, armpl_singlecomplex_t *b,
                           armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrs*, *LAPACKE_dgetrs*, *LAPACKE_sgetrs* and *LAPACKE_zgetrs*. It also exists with a native Fortran interface as *cgetrs*.

4.19.120 LAPACKE_cgetrs_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetrs_work(armpl_int_t matrix_layout, char trans,
                                armpl_int_t n, armpl_int_t nrhs,
                                const armpl_singlecomplex_t *a,
                                armpl_int_t lda, const armpl_int_t *ipiv,
                                armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetrs_work*, *LAPACKE_dgetrs_work*, *LAPACKE_sgetrs_work* and *LAPACKE_zgetrs_work*.

4.19.121 LAPACKE_cgetsls

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetsls(armpl_int_t matrix_layout, char trans,
                            armpl_int_t m, armpl_int_t n, armpl_int_t nrhs,
                            armpl_singlecomplex_t *a, armpl_int_t lda,
                            armpl_singlecomplex_t *b, armpl_int_t ldb);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetsls*, *LAPACKE_dgetsls*, *LAPACKE_sgetsls* and *LAPACKE_zgetsls*. It also exists with a native Fortran interface as *cgetsls*.

4.19.122 LAPACKE_cgetsls_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgetsls_work(armpl_int_t matrix_layout, char trans,
                                 armpl_int_t m, armpl_int_t n,
                                 armpl_int_t nrhs, armpl_singlecomplex_t *a,
                                 armpl_int_t lda, armpl_singlecomplex_t *b,
                                 armpl_int_t ldb, armpl_singlecomplex_t *work,
                                 armpl_int_t lwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgetsls_work*, *LAPACKE_dgetsls_work*, *LAPACKE_sgetsls_work* and *LAPACKE_zgetsls_work*.

4.19.123 LAPACKE_cggbak

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggbak(armpl_int_t matrix_layout, char job, char side,
                           armpl_int_t n, armpl_int_t ilo, armpl_int_t ihi,
                           const float *lscale, const float *rscale,
                           armpl_int_t m, armpl_singlecomplex_t *v,
                           armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer

- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbak*, *LAPACKE_dggbak*, *LAPACKE_sggbak* and *LAPACKE_zggbak*. It also exists with a native Fortran interface as *cggbak*.

4.19.124 LAPACKE_cggbak_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggbak_work(armpl_int_t matrix_layout, char job,
                                char side, armpl_int_t n, armpl_int_t ilo,
                                armpl_int_t ihi, const float *lscale,
                                const float *rscale, armpl_int_t m,
                                armpl_singlecomplex_t *v, armpl_int_t ldv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbak_work*, *LAPACKE_dggbak_work*, *LAPACKE_sggbak_work* and *LAPACKE_zggbak_work*.

4.19.125 LAPACKE_cggbal

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggbal(armpl_int_t matrix_layout, char job, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_int_t *ilo, armpl_int_t *ihi, float *lscale,
                           float *rscale);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbal*, *LAPACKE_dggbal*, *LAPACKE_sggbal* and *LAPACKE_zggbal*. It also exists with a native Fortran interface as *cggbal*.

4.19.126 LAPACKE_cggbal_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggbal_work(armpl_int_t matrix_layout, char job,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
                                armpl_int_t ldb, armpl_int_t *ilo,
                                armpl_int_t *ihi, float *lscale,
                                float *rscale, float *work);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cggbal_work*, *LAPACKE_dggbal_work*, *LAPACKE_sggbal_work* and *LAPACKE_zggbal_work*.

4.19.127 LAPACKE_cgges

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgges(armpl_int_t matrix_layout, char jobvsl, char jobvsr,
                          char sort, LAPACK_C_SELECT2 selctg, armpl_int_t n,
                          armpl_singlecomplex_t *a, armpl_int_t lda,
                          armpl_singlecomplex_t *b, armpl_int_t ldb,
                          armpl_int_t *sdim, armpl_singlecomplex_t *alpha,
                          armpl_singlecomplex_t *beta,
                          armpl_singlecomplex_t *vsl, armpl_int_t ldvsl,
                          armpl_singlecomplex_t *vsr, armpl_int_t ldvsr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgges*, *LAPACKE_dgges*, *LAPACKE_sgges* and *LAPACKE_zgges*. It also exists with a native Fortran interface as *cgges*.

4.19.128 LAPACKE_cgges3

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgges3(armpl_int_t matrix_layout, char jobvsl,
                           char jobvsr, char sort, LAPACK_C_SELECT2 selctg,
                           armpl_int_t n, armpl_singlecomplex_t *a,
                           armpl_int_t lda, armpl_singlecomplex_t *b,
                           armpl_int_t ldb, armpl_int_t *sdim,
                           armpl_singlecomplex_t *alpha,
                           armpl_singlecomplex_t *beta,
                           armpl_singlecomplex_t *vsl, armpl_int_t ldvsl,
                           armpl_singlecomplex_t *vsr, armpl_int_t ldvsr);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

For this routine in other precisions, please see *LAPACKE_cgges3*, *LAPACKE_dgges3*, *LAPACKE_sgges3* and *LAPACKE_zgges3*. It also exists with a native Fortran interface as *cgges3*.

4.19.129 LAPACKE_cgges3_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgges3_work(armpl_int_t matrix_layout, char jobvsl,
                                char jobvsr, char sort,
                                LAPACK_C_SELECT2 selctg, armpl_int_t n,
                                armpl_singlecomplex_t *a, armpl_int_t lda,
                                armpl_singlecomplex_t *b, armpl_int_t ldb,
                                armpl_int_t *sdim,
                                armpl_singlecomplex_t *alpha,
                                armpl_singlecomplex_t *beta,
                                armpl_singlecomplex_t *vsl, armpl_int_t ldvsl,
                                armpl_singlecomplex_t *vsr, armpl_int_t ldvsr,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.130 LAPACKE_cgges_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cgges_work(armpl_int_t matrix_layout, char jobvsl,
                               char jobvsr, char sort,
                               LAPACK_C_SELECT2 selctg, armpl_int_t n,
                               armpl_singlecomplex_t *a, armpl_int_t lda,
                               armpl_singlecomplex_t *b, armpl_int_t ldb,
                               armpl_int_t *sdim,
                               armpl_singlecomplex_t *alpha,
                               armpl_singlecomplex_t *beta,
                               armpl_singlecomplex_t *vsl, armpl_int_t ldvsl,
                               armpl_singlecomplex_t *vsr, armpl_int_t ldvsr,
                               armpl_singlecomplex_t *work, armpl_int_t lwork,
                               float *rwork, armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.

- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

4.19.131 LAPACKE_cggesx

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggesx(armpl_int_t matrix_layout, char jobvsl,
                           char jobvsr, char sort, LAPACK_C_SELECT2 selctg,
                           char sense, armpl_int_t n,
                           armpl_singlecomplex_t *a, armpl_int_t lda,
                           armpl_singlecomplex_t *b, armpl_int_t ldb,
                           armpl_int_t *sdim, armpl_singlecomplex_t *alpha,
                           armpl_singlecomplex_t *beta,
                           armpl_singlecomplex_t *vsl, armpl_int_t ldvsl,
                           armpl_singlecomplex_t *vsr, armpl_int_t ldvsr,
                           float *rconde, float *rcondv);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.

- All scalar quantities passed in by value.
- All arrays are passed in by pointer
- The first parameter is usually `matrix_layout`. This takes a value of either `LAPACK_ROW_MAJOR` or `LAPACK_COL_MAJOR`, depending on whether the data is laid out in memory in row-major or column-major format, respectively.

Related Information

4.19.132 LAPACKE_cggesx_work

Syntax

```
#include "armpl.h"

armpl_int_t LAPACKE_cggesx_work(armpl_int_t matrix_layout, char jobvsl,
                                char jobvsr, char sort,
                                LAPACK_C_SELECT2 selctg, char sense,
                                armpl_int_t n, armpl_singlecomplex_t *a,
                                armpl_int_t lda, armpl_singlecomplex_t *b,
```

(continues on next page)

(continued from previous page)

```
                                armpl_int_t ldb, armpl_int_t *sdim,
                                armpl_singlecomplex_t *alpha,
                                armpl_singlecomplex_t *beta,
                                armpl_singlecomplex_t *vsl, armpl_int_t ldvsl,
                                armpl_singlecomplex_t *vsr, armpl_int_t ldvsr,
                                float *rconde, float *rcondv,
                                armpl_singlecomplex_t *work,
                                armpl_int_t lwork, float *rwork,
                                armpl_int_t *iwork, armpl_int_t liwork,
                                armpl_int_t *bwork);
```

Parameters

LAPACKE routines operate similarly to the equivalent Fortran routine with minor changes.
