WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,18*N) if JOBZ = 'V', and LWORK >= max(1,12*N) if JOBZ = 'N'. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (LIWORK)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N) if the eigenvectors are desired, and LIWORK >= max(1,8*N) if only the eigenvalues are to be computed. If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

On exit, INFO = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = 1X, internal error in DLARRE, if INFO = 2X, internal error in ZLARRV. Here, the digit X = ABS(IINFO) < 10, where IINFO is the nonzero error code returned by DLARRE or ZLARRV, respectively.

Related Information

For this routine in other precisions, please see *cstemr*, *dstemr* and *sstemr*. It also exists with a native C interface as *LAPACKE_zstemr*.

4.11.105 zsteqr

zsteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band complex Hermitian matrix can also be found if ZHETRD or ZHPTRD or ZHBTRD has been used to reduce this matrix to tridiagonal form.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsteqr(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsteqr_(const char *compz, const armpl_int_t *n, double *d, double *e,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz, double *work,
             armpl_int_t *info, ... );
```

Parameters

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors of the original Hermitian matrix. On entry, Z must contain the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

D Input and output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if eigenvectors are desired, then LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (max(1,2*N-2)). If COMPZ = 'N', then WORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: the algorithm has failed to find all the eigenvalues in a total of 30* N iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is unitarily similar to the original matrix.

Related Information

For this routine in other precisions, please see *csteqr*, *dsteqr* and *ssteqr*. It also exists with a native C interface as *LAPACKE_zsteqr*.

4.11.106 zungtr

zungtr generates a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by ZHETRD:

if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine zungtr(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zungtr_(const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A contains elementary reflectors from ZHETRD; = 'L': Lower triangle of A contains elementary reflectors from ZHETRD.

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by ZHETRD. On exit, the N-by-N unitary matrix Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= N.

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZHETRD.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= N-1. For optimum performance LWORK >= (N-1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cungtr*. It also exists with a native C interface as *LAPACKE_zungtr*.

4.11.107 zunm22

```
ZUNM22 overwrites the general complex M-by-N matrix C with

                 SIDE = 'L'     SIDE = 'R'
 TRANS = 'N':      Q * C          C * Q
 TRANS = 'C':      Q**H * C       C * Q**H

 where Q is a complex unitary matrix of order NQ, with NQ = M if
 SIDE = 'L' and NQ = N if SIDE = 'R'.
 The unitary matrix Q processes a 2-by-2 block structure

        [  Q11  Q12  ]
    Q = [            ]
        [  Q21  Q22  ],

 where Q12 is an N1-by-N1 lower triangular matrix and Q21 is an
 N2-by-N2 upper triangular matrix.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zunm22(SIDE, TRANS, M, N, N1, N2, Q, LDQ, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zunm22_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *n1,
             const armpl_int_t *n2, const armpl_doublecomplex_t *q,
             const armpl_int_t *ldq, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose); = 'C': apply Q^H (Conjugate transpose).

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

N1 Input parameter.

N2 Input parameter.

N1 is INTEGER

N2 is INTEGER The dimension of Q12 and Q21, respectively. N1, N2 >= 0. The following requirement must be satisfied: N1 + N2 = M if SIDE = 'L' and N1 + N2 = N if SIDE = 'R'.

Q Input parameter.

Q is COMPLEX*16

Q is an array, dimension. (LDQ, M) if SIDE = 'L' (LDQ, N) if SIDE = 'R'

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, M) if SIDE = 'L'; LDQ >= max(1, N) if SIDE = 'R'.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunm22*.

4.11.108 zunmtr

zunmtr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by ZHETRD:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine zunmtr(SIDE, UPLO, TRANS, M, N, A, LDA, TAU, C, LDC, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zunmtr_(const char *side, const char *uplo, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A contains elementary reflectors from ZHETRD; = 'L': Lower triangle of A contains elementary reflectors from ZHETRD.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L' (LDA, N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by ZHETRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M) if SIDE = 'L'; LDA >= max(1, N) if SIDE = 'R'.

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZHETRD.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >=M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunmtr*. It also exists with a native C interface as *LAPACKE_zunmtr*.

4.11.109 zupgtr

zupgtr generates a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by ZHPTRD using packed storage:

if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine zupgtr(UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zupgtr_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *ap,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *q,
             const armpl_int_t *ldq, armpl_doublecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular packed storage used in previous call to ZHPTRD; = 'L': Lower triangular packed storage used in previous call to ZHPTRD.

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The vectors which define the elementary reflectors, as returned by ZHPTRD.

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZHPTRD.

Q Output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). The N-by-N unitary matrix Q.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N-1) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cupgtr*. It also exists with a native C interface as *LAPACKE_zupgtr*.

4.11.110 zupmtr

zupmtr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'      SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by ZHPTRD using packed storage:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine zupmtr(SIDE, UPLO, TRANS, M, N, AP, TAU, C, LDC, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zupmtr_(const char *side, const char *uplo, const char *trans,
             const armpl_int_t *m, const armpl_int_t *n,
             const armpl_doublecomplex_t *ap,
             const armpl_doublecomplex_t *tau, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, armpl_doublecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular packed storage used in previous call to ZHPTRD; = 'L': Lower triangular packed storage used in previous call to ZHPTRD.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension. (M*(M+1)/2) if SIDE = 'L' (N*(N+1)/2) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by ZHPTRD. AP is modified by the routine but restored on exit.

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (M-1) if SIDE = 'L'. or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZHPTRD.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension. (N) if SIDE = 'L' (M) if SIDE = 'R'

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cupmtr*. It also exists with a native C interface as *LAPACKE_zupmtr*.

4.12 LAPACK generalized symmetric eigenvalues routines

4.12.1 chbgst

chbgst reduces a complex Hermitian-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y, such that C has the same bandwidth as A.

B must have been previously factorized as S^H *S by CPBSTF, using a split Cholesky factorization. A is overwritten by C = X^H *A*X, where X = S**(-1)*Q and Q is a unitary matrix chosen to preserve the bandwidth of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbgst(VECT, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, X, LDX, WORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chbgst_(const char *vect, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *ka, const armpl_int_t *kb,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             const armpl_singlecomplex_t *bb, const armpl_int_t *ldbb,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': do not form the transformation matrix X; = 'V': form X.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= KB >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the transformed matrix X^H *A*X, stored in the same format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input parameter.

BB is COMPLEX

BB is an array, dimension (LDBB, N). The banded factor S from the split Cholesky factorization of B, as returned by CPBSTF, stored in the first kb+1 rows of the array.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, N). If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N) if VECT = 'V'; LDX >= 1 otherwise.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zhbgst*. It also exists with a native C interface as *LAPACKE_chbgst*.

4.12.2 chbgv

chbgv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbgv(JOBZ, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, W, Z, LDZ, WORK,
                 RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chbgv_(const char *jobz, const char *uplo, const armpl_int_t *n,
            const armpl_int_t *ka, const armpl_int_t *kb,
            armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
            armpl_singlecomplex_t *bb, const armpl_int_t *ldbb, float *w,
            armpl_singlecomplex_t *z, const armpl_int_t *ldz,
            armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
            ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is COMPLEX

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^H *S, as returned by CPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z^H *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then CPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *zhbgv*. It also exists with a native C interface as *LAPACKE_chbgv*.

4.12.3 chbgvd

chbgvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbgvd(JOBZ, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, W, Z, LDZ, WORK,
                  LWORK, RWORK, LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chbgvd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *ka, const armpl_int_t *kb,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             armpl_singlecomplex_t *bb, const armpl_int_t *ldbb, float *w,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is COMPLEX

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^H *S, as returned by CPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z^H *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= N. If JOBZ = 'V' and N > 1, LWORK >= 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO=0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK >= 1. If JOBZ = 'N' and N > 1, LRWORK >= N. If JOBZ = 'V' and N > 1, LRWORK >= 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO=0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then CPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *zhbgvd*. It also exists with a native C interface as *LAPACKE_chbgvd*.

4.12.4 chbgvx

chbgvx computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbgvx(JOBZ, RANGE, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, Q, LDQ,
                  VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ, WORK, RWORK, IWORK,
                  IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void chbgvx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, const armpl_int_t *ka,
             const armpl_int_t *kb, armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, armpl_singlecomplex_t *bb,
             const armpl_int_t *ldbb, armpl_singlecomplex_t *q,
             const armpl_int_t *ldq, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
```

(continues on next page)

(continued from previous page)

```
                const float *abstol, armpl_int_t *m, float *w,
                armpl_singlecomplex_t *z, const armpl_int_t *ldz,
                armpl_singlecomplex_t *work, float *rwork, armpl_int_t *iwork,
                armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is COMPLEX

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as

follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^H *S, as returned by CPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

Q Output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the n-by-n matrix used in the reduction of A*x = (lambda)*B*x to standard form, i.e. C*x = (lambda)*x, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z^H *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: then i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then CPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *zhbgvx*. It also exists with a native C interface as *LAPACKE_chbgvx*.

4.12.5 chegst

chegst reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^H or L^H *A*L.

B must have been previously factorized as U^H *U or L*L^H by CPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine chegst(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void chegst_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

= 1: compute inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H); = 2 or 3: compute U*A*U^H or L^H *A*L.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored and B is factored as U^H *U; = 'L': Lower triangle of A is stored and B is factored as L*L^H .

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhegst*. It also exists with a native C interface as *LAPACKE_chegst*.

4.12.6 chegv

chegv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine chegv(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK, RWORK,
                 INFO)
```

C specification:

```
#include "armpl.h"

void chegv_(const armpl_int_t *itype, const char *jobz, const char *uplo,
            const armpl_int_t *n, armpl_singlecomplex_t *a,
            const armpl_int_t *lda, armpl_singlecomplex_t *b,
            const armpl_int_t *ldb, float *w, armpl_singlecomplex_t *work,
            const armpl_int_t *lwork, float *rwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B*Z = I; if ITYPE = 3, Z^H *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the Hermitian positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,2*N-1). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: CPOTRF or CHEEV returned an error code: <= N: if INFO = i, CHEEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of

order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *zhegv*. It also exists with a native C interface as *LAPACKE_chegv*.

4.12.7 chegvd

chegvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine chegvd(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK, RWORK,
                  LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chegvd_(const armpl_int_t *itype, const char *jobz, const char *uplo,
             const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, float *w, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork,
             const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B*Z = I; if ITYPE = 3, Z^H *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= N + 1. If JOBZ = 'V' and N > 1, LWORK >= 2* N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. If N <= 1, LRWORK >= 1. If JOBZ = 'N' and N > 1, LRWORK >= N. If JOBZ = 'V' and N > 1, LRWORK >= 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK >= 1. If JOBZ = 'N' and N > 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: CPOTRF or CHEEVD returned an error code: <= N: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1); > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *zhegvd*. It also exists with a native C interface as *LAPACKE_chegvd*.

4.12.8 chegvx

chegvx computes selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine chegvx(ITYPE, JOBZ, RANGE, UPLO, N, A, LDA, B, LDB, VL, VU, IL, IU,
                  ABSTOL, M, W, Z, LDZ, WORK, LWORK, RWORK, IWORK, IFAIL,
                  INFO)
```

C specification:

```
#include "armpl.h"

void chegvx_(const armpl_int_t *itype, const char *jobz, const char *range,
             const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, armpl_int_t *iwork, armpl_int_t *ifail,
             armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing C to tridiagonal form, where C is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,2*N). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: CPOTRF or CHEEVX returned an error code: <= N: if INFO = i, CHEEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *zhegvx*. It also exists with a native C interface as *LAPACKE_chegvx*.

4.12.9 chpgst

chpgst reduces a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^H or L^H *A*L.

B must have been previously factorized as U^H *U or L*L^H by CPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpgst(ITYPE, UPLO, N, AP, BP, INFO)
```

C specification:

```
#include "armpl.h"

void chpgst_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, const armpl_singlecomplex_t *bp,
             armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

= 1: compute inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H); = 2 or 3: compute U*A*U^H or L^H *A*L.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored and B is factored as U^H *U; = 'L': Lower triangle of A is stored and B is factored as L*L^H .

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP Input parameter.

BP is COMPLEX

BP is an array, dimension (N*(N+1)/2). The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by CPPTRF.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhpgst*. It also exists with a native C interface as *LAPACKE_chpgst*.

4.12.10 chpgv

chpgv computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpgv(ITYPE, JOBZ, UPLO, N, AP, BP, W, Z, LDZ, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chpgv_(const armpl_int_t *itype, const char *jobz, const char *uplo,
            const armpl_int_t *n, armpl_singlecomplex_t *ap,
            armpl_singlecomplex_t *bp, float *w, armpl_singlecomplex_t *z,
            const armpl_int_t *ldz, armpl_singlecomplex_t *work, float *rwork,
            armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is COMPLEX

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H , in the same storage format as B.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B* Z = I; if ITYPE = 3, Z^H *inv(B)* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (max(1, 2*N-1)) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: CPPTRF or CHPEV returned an error code: <= N: if INFO = i, CHPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *zhpgv*. It also exists with a native C interface as *LAPACKE_chpgv*.

4.12.11 chpgvd

`chpgvd` computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpgvd(ITYPE, JOBZ, UPLO, N, AP, BP, W, Z, LDZ, WORK, LWORK, RWORK,
                  LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chpgvd_(const armpl_int_t *itype, const char *jobz, const char *uplo,
             const armpl_int_t *n, armpl_singlecomplex_t *ap,
             armpl_singlecomplex_t *bp, float *w, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork,
             const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is COMPLEX

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H , in the same storage format as B.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B* Z = I; if ITYPE = 3, Z^H *inv(B)* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the required LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= N. If JOBZ = 'V' and N > 1, LWORK >= 2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the required LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK >= 1. If JOBZ = 'N' and N > 1, LRWORK >= N. If JOBZ = 'V' and N > 1, LRWORK >= 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the required LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: CPPTRF or CHPEVD returned an error code: <= N: if INFO = i, CHPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *zhpgvd*. It also exists with a native C interface as *LAPACKE_chpgvd*.

4.12.12 chpgvx

chpgvx computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine chpgvx(ITYPE, JOBZ, RANGE, UPLO, N, AP, BP, VL, VU, IL, IU, ABSTOL,
                  M, W, Z, LDZ, WORK, RWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void chpgvx_(const armpl_int_t *itype, const char *jobz, const char *range,
             const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, armpl_singlecomplex_t *bp,
             const float *vl, const float *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const float *abstol, armpl_int_t *m,
             float *w, armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is COMPLEX

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H , in the same storage format as B.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B* Z = I; if ITYPE = 3, Z^H *inv(B)* Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: CPPTRF or CHPEVX returned an error code: <= N: if INFO = i, CHPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

For this routine in other precisions, please see *zhpgvx*. It also exists with a native C interface as *LAPACKE_chpgvx*.

4.12.13 cpbstf

cpbstf computes a split Cholesky factorization of a complex Hermitian positive definite band matrix A.

This routine is designed to be used in conjunction with CHBGST.

The factorization has the form A = S^H *S where S is a band matrix of the same bandwidth as A and the following structure:

```
S = ( U    )
    ( M  L )
```

where U is upper triangular of order m = (n+kd)/2, and L is lower triangular of order n-m.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpbstf(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void cpbstf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the factor S from the split Cholesky factorization A = S^H *S. See Further Details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

Related Information

For this routine in other precisions, please see *dpbstf*, *spbstf* and *zpbstf*. It also exists with a native C interface as *LAPACKE_cpbstf*.

4.12.14 dpbstf

dpbstf computes a split Cholesky factorization of a real symmetric positive definite band matrix A.

This routine is designed to be used in conjunction with DSBGST.

The factorization has the form A = S^T *S where S is a band matrix of the same bandwidth as A and the following structure:

```
S = ( U    )
    ( M  L )
```

where U is upper triangular of order m = (n+kd)/2, and L is lower triangular of order n-m.

Syntax

Fortran specification:

```
use armpl_library

subroutine dpbstf(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void dpbstf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             double *ab, const armpl_int_t *ldab, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the factor S from the split Cholesky factorization A = S^T *S. See Further Details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

Related Information

For this routine in other precisions, please see *cpbstf*, *spbstf* and *zpbstf*. It also exists with a native C interface as *LAPACKE_dpbstf*.

4.12.15 dsbgst

dsbgst reduces a real symmetric-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y, such that C has the same bandwidth as A.

B must have been previously factorized as S^T *S by DPBSTF, using a split Cholesky factorization. A is overwritten by C = X^T *A*X, where X = S**(-1)*Q and Q is an orthogonal matrix chosen to preserve the bandwidth of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbgst(VECT, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, X, LDX, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dsbgst_(const char *vect, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *ka, const armpl_int_t *kb, double *ab,
             const armpl_int_t *ldab, const double *bb,
             const armpl_int_t *ldbb, double *x, const armpl_int_t *ldx,
             double *work, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': do not form the transformation matrix X; = 'V': form X.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= KB >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the transformed matrix X^T *A*X, stored in the same format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input parameter.

BB is DOUBLE PRECISION

BB is an array, dimension (LDBB, N). The banded factor S from the split Cholesky factorization of B, as returned by DPBSTF, stored in the first KB+1 rows of the array.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

X Output parameter.

X is DOUBLE PRECISION

X is an array, dimension (LDX, N). If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N) if VECT = 'V'; LDX >= 1 otherwise.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *ssbgst*. It also exists with a native C interface as *LAPACKE_dsbgst*.

4.12.16 dsbgv

dsbgv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbgv(JOBZ, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, W, Z, LDZ, WORK,
                 INFO)
```

C specification:

```
#include "armpl.h"

void dsbgv_(const char *jobz, const char *uplo, const armpl_int_t *n,
            const armpl_int_t *ka, const armpl_int_t *kb, double *ab,
            const armpl_int_t *ldab, double *bb, const armpl_int_t *ldbb,
```

(continues on next page)

(continued from previous page)

```
            double *w, double *z, const armpl_int_t *ldz, double *work,
            armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is DOUBLE PRECISION

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^T *S, as returned by DPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z^T *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then DPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *ssbgv*. It also exists with a native C interface as *LAPACKE_dsbgv*.

4.12.17 dsbgvd

dsbgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbgvd(JOBZ, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, W, Z, LDZ, WORK,
                  LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsbgvd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *ka, const armpl_int_t *kb, double *ab,
             const armpl_int_t *ldab, double *bb, const armpl_int_t *ldbb,
             double *w, double *z, const armpl_int_t *ldz, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is DOUBLE PRECISION

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(ka+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^T *S, as returned by DPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so Z^T *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 2*N. If JOBZ = 'V' and N > 1, LWORK >= 1 + 5* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if LIWORK > 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then DPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *ssbgvd*. It also exists with a native C interface as *LAPACKE_dsbgvd*.

4.12.18 dsbgvx

`dsbgvx` computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbgvx(JOBZ, RANGE, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, Q, LDQ,
                  VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ, WORK, IWORK, IFAIL,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dsbgvx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, const armpl_int_t *ka,
             const armpl_int_t *kb, double *ab, const armpl_int_t *ldab,
             double *bb, const armpl_int_t *ldbb, double *q,
             const armpl_int_t *ldq, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const double *abstol, armpl_int_t *m, double *w, double *z,
             const armpl_int_t *ldz, double *work, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

`JOBZ` is `CHARACTER*1`

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

`RANGE` is `CHARACTER*1`

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (`VL`,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

`N` is `INTEGER`

The order of the matrices A and B. `N` >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is DOUBLE PRECISION

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(ka+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^T *S, as returned by DPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the n-by-n matrix used in the reduction of A*x = (lambda)*B*x to standard form, i.e. C*x = (lambda)*x, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so Z^T *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (M)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvalues that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit < 0 : if INFO = -i, the i-th argument had an illegal value <= N: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in IFAIL. > N : DPBSTF returned an error code; i.e., if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *ssbgvx*. It also exists with a native C interface as *LAPACKE_dsbgvx*.

4.12.19 dspgst

dspgst reduces a real symmetric-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^T or L^T*A*L.

B must have been previously factorized as U^T*U or L*L^T by DPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspgst(ITYPE, UPLO, N, AP, BP, INFO)
```

C specification:

```
#include "armpl.h"

void dspgst_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             double *ap, const double *bp, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

= 1: compute inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T); = 2 or 3: compute U*A*U^T or L^T*A*L.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored and B is factored as U^T*U; = 'L': Lower triangle of A is stored and B is factored as L*L^T .

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP Input parameter.

BP is DOUBLE PRECISION

BP is an array, dimension (N*(N+1)/2). The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by DPPTRF.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sspgst*. It also exists with a native C interface as *LAPACKE_dspgst*.

4.12.20 dspgv

dspgv computes all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspgv(ITYPE, JOBZ, UPLO, N, AP, BP, W, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dspgv_(const armpl_int_t *itype, const char *jobz, const char *uplo,
            const armpl_int_t *n, double *ap, double *bp, double *w,
            double *z, const armpl_int_t *ldz, double *work,
            armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is DOUBLE PRECISION

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T , in the same storage format as B.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: DPPTRF or DSPEV returned an error code: <= N: if INFO = i, DSPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero. > N: if INFO = n + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *sspgv*. It also exists with a native C interface as *LAPACKE_dspgv*.

4.12.21 dspgvd

`dspgvd` computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspgvd(ITYPE, JOBZ, UPLO, N, AP, BP, W, Z, LDZ, WORK, LWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dspgvd_(const armpl_int_t *itype, const char *jobz, const char *uplo,
             const armpl_int_t *n, double *ap, double *bp, double *w,
             double *z, const armpl_int_t *ldz, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

`ITYPE` is `INTEGER`

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

`JOBZ` is `CHARACTER*1`

= ‘`N`’: Compute eigenvalues only; = ‘V’: Compute eigenvalues and eigenvectors.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= ‘`U`’: Upper triangles of A and B are stored; = ‘`L`’: Lower triangles of A and B are stored.

N Input parameter.

`N` is `INTEGER`

The order of the matrices A and B. `N` >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is DOUBLE PRECISION

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T , in the same storage format as B.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the required LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 2*N. If JOBZ = 'V' and N > 1, LWORK >= 1 + 6* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the required LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: DPPTRF or DSPEVD returned an error code: <= N: if INFO = i, DSPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *sspgvd*. It also exists with a native C interface as *LAPACKE_dspgvd*.

4.12.22 dspgvx

dspgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed storage, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dspgvx(ITYPE, JOBZ, RANGE, UPLO, N, AP, BP, VL, VU, IL, IU, ABSTOL,
                  M, W, Z, LDZ, WORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void dspgvx_(const armpl_int_t *itype, const char *jobz, const char *range,
             const char *uplo, const armpl_int_t *n, double *ap, double *bp,
             const double *vl, const double *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const double *abstol, armpl_int_t *m,
             double *w, double *z, const armpl_int_t *ldz, double *work,
             armpl_int_t *iwork, armpl_int_t *ifail, armpl_int_t *info,
             ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A and B are stored; = 'L': Lower triangle of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrix pencil (A,B). N >= 0.

AP Input and output parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is DOUBLE PRECISION

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^T *U$ or $B = L*L^T$, in the same storage format as B.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (8*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: DPPTRF or DSPEVX returned an error code: <= N: if INFO = i, DSPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *sspgvx*. It also exists with a native C interface as *LAPACKE_dspgvx*.

4.12.23 dsygst

`dsygst` reduces a real symmetric-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^T or L^T*A*L.

B must have been previously factorized as U^T*U or L*L^T by DPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsygst(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dsygst_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             double *a, const armpl_int_t *lda, const double *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

`ITYPE` is `INTEGER`

= 1: compute inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T); = 2 or 3: compute U*A*U^T or L^T*A*L.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= '`U`': Upper triangle of `A` is stored and `B` is factored as U^T*U; = '`L`': Lower triangle of `A` is stored and `B` is factored as L*L^T.

N Input parameter.

`N` is `INTEGER`

The order of the matrices `A` and `B`. `N` >= 0.

A Input and output parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). On entry, the symmetric matrix `A`. If `UPLO` = '`U`', the leading N-by-N upper triangular part of `A` contains the upper triangular part of the matrix `A`, and the strictly lower triangular part of `A` is not referenced. If `UPLO` = '`L`', the leading N-by-N lower triangular part of `A` contains the lower triangular part of the matrix `A`, and the strictly upper triangular part of `A` is not referenced.

On exit, if `INFO` = 0, the transformed matrix, stored in the same format as `A`.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). The triangular factor from the Cholesky factorization of B, as returned by DPOTRF.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ssygst*. It also exists with a native C interface as *LAPACKE_dsygst*.

4.12.24 dsygv

dsygv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsygv(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsygv_(const armpl_int_t *itype, const char *jobz, const char *uplo,
            const armpl_int_t *n, double *a, const armpl_int_t *lda,
            double *b, const armpl_int_t *ldb, double *w, double *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B*Z = I; if ITYPE = 3, Z^T *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the symmetric positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,3*N-1). For optimal efficiency, LWORK >= (NB+2)*N, where NB is the blocksize for DSYTRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: DPOTRF or DSYEV returned an error code: <= N: if INFO = i, DSYEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *ssygv*. It also exists with a native C interface as *LAPACKE_dsygv*.

4.12.25 dsygvd

dsygvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsygvd(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsygvd_(const armpl_int_t *itype, const char *jobz, const char *uplo,
             const armpl_int_t *n, double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, double *w, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B*Z = I; if ITYPE = 3, Z^T *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 2*N+1. If JOBZ = 'V' and N > 1, LWORK >= 1 + 6* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK >= 1. If JOBZ = 'N' and N > 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: DPOTRF or DSYEVD returned an error code: <= N: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1); > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *ssygvd*. It also exists with a native C interface as *LAPACKE_dsygvd*.

4.12.26 dsygvx

dsygvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsygvx(ITYPE, JOBZ, RANGE, UPLO, N, A, LDA, B, LDB, VL, VU, IL, IU,
                  ABSTOL, M, W, Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void dsygvx_(const armpl_int_t *itype, const char *jobz, const char *range,
             const char *uplo, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
             const double *vl, const double *vu, const armpl_int_t *il,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *iu, const double *abstol, armpl_int_t *m,
                double *w, double *z, const armpl_int_t *ldz, double *work,
                const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *ifail,
                armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A and B are stored; = 'L': Lower triangle of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrix pencil (A, B). N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing C to tridiagonal form, where C is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,8*N). For optimal efficiency, LWORK >= (NB+3)*N, where NB is the blocksize for DSYTRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: DPOTRF or DSYEVX returned an error code: <= N: if INFO = i, DSYEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *ssygvx*. It also exists with a native C interface as *LAPACKE_dsygvx*.

4.12.27 spbstf

spbstf computes a split Cholesky factorization of a real symmetric positive definite band matrix A.

This routine is designed to be used in conjunction with SSBGST.

The factorization has the form A = S^T *S where S is a band matrix of the same bandwidth as A and the following structure:

```
S = ( U    )
    ( M  L )
```

where U is upper triangular of order m = (n+kd)/2, and L is lower triangular of order n-m.

Syntax

Fortran specification:

```
use armpl_library

subroutine spbstf(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void spbstf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             float *ab, const armpl_int_t *ldab, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the factor S from the split Cholesky factorization A = S^T *S. See Further Details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

Related Information

For this routine in other precisions, please see *cpbstf*, *dpbstf* and *zpbstf*. It also exists with a native C interface as *LAPACKE_spbstf*.

4.12.28 ssbgst

ssbgst reduces a real symmetric-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y, such that C has the same bandwidth as A.

B must have been previously factorized as S^T *S by SPBSTF, using a split Cholesky factorization. A is overwritten by C = X^T *A*X, where X = S**(-1)*Q and Q is an orthogonal matrix chosen to preserve the bandwidth of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbgst(VECT, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, X, LDX, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ssbgst_(const char *vect, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *ka, const armpl_int_t *kb, float *ab,
             const armpl_int_t *ldab, const float *bb,
             const armpl_int_t *ldbb, float *x, const armpl_int_t *ldx,
             float *work, armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': do not form the transformation matrix X; = 'V': form X.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= KB >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as

follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the transformed matrix X^T *A*X, stored in the same format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input parameter.

BB is REAL

BB is an array, dimension (LDBB, N). The banded factor S from the split Cholesky factorization of B, as returned by SPBSTF, stored in the first KB+1 rows of the array.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

X Output parameter.

X is REAL

X is an array, dimension (LDX, N). If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N) if VECT = 'V'; LDX >= 1 otherwise.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dsbgst*. It also exists with a native C interface as *LAPACKE_ssbgst*.

4.12.29 ssbgv

ssbgv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbgv(JOBZ, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, W, Z, LDZ, WORK,
                 INFO)
```

C specification:

```
#include "armpl.h"

void ssbgv_(const char *jobz, const char *uplo, const armpl_int_t *n,
            const armpl_int_t *ka, const armpl_int_t *kb, float *ab,
            const armpl_int_t *ldab, float *bb, const armpl_int_t *ldbb,
            float *w, float *z, const armpl_int_t *ldz, float *work,
            armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is REAL

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^T *S, as returned by SPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z^T *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then SPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dsbgv*. It also exists with a native C interface as *LAPACKE_ssbgv*.

4.12.30 ssbgvd

ssbgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbgvd(JOBZ, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, W, Z, LDZ, WORK,
                  LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssbgvd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *ka, const armpl_int_t *kb, float *ab,
             const armpl_int_t *ldab, float *bb, const armpl_int_t *ldbb,
             float *w, float *z, const armpl_int_t *ldz, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is REAL

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(ka+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^T *S, as returned by SPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so Z^T *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 3*N. If JOBZ = 'V' and N > 1, LWORK >= 1 + 5* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if LIWORK > 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then SPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dsbgvd*. It also exists with a native C interface as *LAPACKE_ssbgvd*.

4.12.31 ssbgvx

ssbgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbgvx(JOBZ, RANGE, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, Q, LDQ,
                  VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ, WORK, IWORK, IFAIL,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ssbgvx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, const armpl_int_t *ka,
             const armpl_int_t *kb, float *ab, const armpl_int_t *ldab,
             float *bb, const armpl_int_t *ldbb, float *q,
             const armpl_int_t *ldq, const float *vl, const float *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const float *abstol, armpl_int_t *m, float *w, float *z,
             const armpl_int_t *ldz, float *work, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is REAL

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(ka+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^T *S, as returned by SPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the n-by-n matrix used in the reduction of A*x = (lambda)*B*x to standard form, i.e. C*x = (lambda)*x, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so Z^T *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (M)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvalues that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit < 0 : if INFO = -i, the i-th argument had an illegal value <= N: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in IFAIL. > N : SPBSTF returned an error code; i.e., if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dsbgvx*. It also exists with a native C interface as *LAPACKE_ssbgvx*.

4.12.32 sspgst

sspgst reduces a real symmetric-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^T or L^T*A*L.

B must have been previously factorized as U^T*U or L*L^T by SPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspgst(ITYPE, UPLO, N, AP, BP, INFO)
```

C specification:

```
#include "armpl.h"

void sspgst_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             float *ap, const float *bp, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

= 1: compute inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T); = 2 or 3: compute U*A*U^T or L^T*A*L.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored and B is factored as U^T*U; = 'L': Lower triangle of A is stored and B is factored as L*L^T .

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP Input parameter.

BP is REAL

BP is an array, dimension (N*(N+1)/2). The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by SPPTRF.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dspgst*. It also exists with a native C interface as *LAPACKE_sspgst*.

4.12.33 sspgv

sspgv computes all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspgv(ITYPE, JOBZ, UPLO, N, AP, BP, W, Z, LDZ, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sspgv_(const armpl_int_t *itype, const char *jobz, const char *uplo,
            const armpl_int_t *n, float *ap, float *bp, float *w, float *z,
            const armpl_int_t *ldz, float *work, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is REAL

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T , in the same storage format as B.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: SPPTRF or SSPEV returned an error code: <= N: if INFO = i, SSPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero. > N: if INFO = n + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dspgv*. It also exists with a native C interface as *LAPACKE_sspgv*.

4.12.34 sspgvd

`sspgvd` computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspgvd(ITYPE, JOBZ, UPLO, N, AP, BP, W, Z, LDZ, WORK, LWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sspgvd_(const armpl_int_t *itype, const char *jobz, const char *uplo,
             const armpl_int_t *n, float *ap, float *bp, float *w, float *z,
             const armpl_int_t *ldz, float *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, const armpl_int_t *liwork, armpl_int_t *info,
             ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is REAL

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as B.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the required LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 2*N. If JOBZ = 'V' and N > 1, LWORK >= 1 + 6* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the required LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: SPPTRF or SSPEVD returned an error code: <= N: if INFO = i, SSPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dspgvd*. It also exists with a native C interface as *LAPACKE_sspgvd*.

4.12.35 sspgvx

sspgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed storage, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine sspgvx(ITYPE, JOBZ, RANGE, UPLO, N, AP, BP, VL, VU, IL, IU, ABSTOL,
                  M, W, Z, LDZ, WORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void sspgvx_(const armpl_int_t *itype, const char *jobz, const char *range,
             const char *uplo, const armpl_int_t *n, float *ap, float *bp,
             const float *vl, const float *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const float *abstol, armpl_int_t *m,
             float *w, float *z, const armpl_int_t *ldz, float *work,
             armpl_int_t *iwork, armpl_int_t *ifail, armpl_int_t *info,
             ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A and B are stored; = 'L': Lower triangle of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrix pencil (A,B). N >= 0.

AP Input and output parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is REAL

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^T *U$ or $B = L*L^T$, in the same storage format as B.

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (8*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: SPPTRF or SSPEVX returned an error code: <= N: if INFO = i, SSPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dspgvx*. It also exists with a native C interface as *LAPACKE_sspgvx*.

4.12.36 ssygst

`ssygst` reduces a real symmetric-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^T or L^T*A*L.

B must have been previously factorized as U^T*U or L*L^T by SPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssygst(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ssygst_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             float *a, const armpl_int_t *lda, const float *b,
             const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

`ITYPE` is `INTEGER`

= 1: compute inv(U^T)*A*inv(U) or inv(L)*A*inv(L^T); = 2 or 3: compute U*A*U^T or L^T*A*L.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= '`U`': Upper triangle of `A` is stored and `B` is factored as U^T*U; = '`L`': Lower triangle of `A` is stored and `B` is factored as L*L^T.

N Input parameter.

`N` is `INTEGER`

The order of the matrices `A` and `B`. `N` >= 0.

A Input and output parameter.

`A` is `REAL`

`A` is an array, dimension (`LDA`, `N`). On entry, the symmetric matrix `A`. If `UPLO` = '`U`', the leading N-by-N upper triangular part of `A` contains the upper triangular part of the matrix `A`, and the strictly lower triangular part of `A` is not referenced. If `UPLO` = '`L`', the leading N-by-N lower triangular part of `A` contains the lower triangular part of the matrix `A`, and the strictly upper triangular part of `A` is not referenced.

On exit, if `INFO` = 0, the transformed matrix, stored in the same format as `A`.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is REAL

B is an array, dimension (LDB, N). The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsygst*. It also exists with a native C interface as *LAPACKE_ssygst*.

4.12.37 ssygv

ssygv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssygv(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssygv_(const armpl_int_t *itype, const char *jobz, const char *uplo,
            const armpl_int_t *n, float *a, const armpl_int_t *lda, float *b,
            const armpl_int_t *ldb, float *w, float *work,
            const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B*Z = I; if ITYPE = 3, Z^T *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the symmetric positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,3*N-1). For optimal efficiency, LWORK >= (NB+2)*N, where NB is the blocksize for SSYTRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: SPOTRF or SSYEV returned an error code: <= N: if INFO = i, SSYEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dsygv*. It also exists with a native C interface as *LAPACKE_ssygv*.

4.12.38 ssygvd

ssygvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssygvd(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK, IWORK,
                  LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssygvd_(const armpl_int_t *itype, const char *jobz, const char *uplo,
             const armpl_int_t *n, float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, float *w, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B*Z = I; if ITYPE = 3, Z^T *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 2*N+1. If JOBZ = 'V' and N > 1, LWORK >= 1 + 6* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK >= 1. If JOBZ = 'N' and N > 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: SPOTRF or SSYEVD returned an error code: <= N: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1); > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dsygvd*. It also exists with a native C interface as *LAPACKE_ssygvd*.

4.12.39 ssygvx

ssygvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssygvx(ITYPE, JOBZ, RANGE, UPLO, N, A, LDA, B, LDB, VL, VU, IL, IU,
                  ABSTOL, M, W, Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void ssygvx_(const armpl_int_t *itype, const char *jobz, const char *range,
             const char *uplo, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
             const float *vl, const float *vu, const armpl_int_t *il,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *iu, const float *abstol, armpl_int_t *m,
                float *w, float *z, const armpl_int_t *ldz, float *work,
                const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *ifail,
                armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A and B are stored; = 'L': Lower triangle of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrix pencil (A, B). N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing C to tridiagonal form, where C is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,8*N). For optimal efficiency, LWORK >= (NB+3)*N, where NB is the blocksize for SSYTRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: SPOTRF or SSYEVX returned an error code: <= N: if INFO = i, SSYEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dsygvx*. It also exists with a native C interface as *LAPACKE_ssygvx*.

4.12.40 zhbgst

zhbgst reduces a complex Hermitian-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y, such that C has the same bandwidth as A.

B must have been previously factorized as S^H *S by ZPBSTF, using a split Cholesky factorization. A is overwritten by C = X^H *A*X, where X = S**(-1)*Q and Q is a unitary matrix chosen to preserve the bandwidth of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbgst(VECT, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, X, LDX, WORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhbgst_(const char *vect, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *ka, const armpl_int_t *kb,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             const armpl_doublecomplex_t *bb, const armpl_int_t *ldbb,
             armpl_doublecomplex_t *x, const armpl_int_t *ldx,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': do not form the transformation matrix X; = 'V': form X.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= KB >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the transformed matrix X^H *A*X, stored in the same format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input parameter.

BB is COMPLEX*16

BB is an array, dimension (LDBB, N). The banded factor S from the split Cholesky factorization of B, as returned by ZPBSTF, stored in the first kb+1 rows of the array.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

X Output parameter.

X is COMPLEX*16

X is an array, dimension (LDX, N). If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, N) if VECT = 'V'; LDX >= 1 otherwise.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *chbgst*. It also exists with a native C interface as *LAPACKE_zhbgst*.

4.12.41 zhbgv

zhbgv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbgv(JOBZ, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, W, Z, LDZ, WORK,
                 RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhbgv_(const char *jobz, const char *uplo, const armpl_int_t *n,
            const armpl_int_t *ka, const armpl_int_t *kb,
            armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
            armpl_doublecomplex_t *bb, const armpl_int_t *ldbb, double *w,
            armpl_doublecomplex_t *z, const armpl_int_t *ldz,
            armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
            ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is COMPLEX*16

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as

follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^H *S, as returned by ZPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z^H *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then ZPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chbgv*. It also exists with a native C interface as *LAPACKE_zhbgv*.

4.12.42 zhbgvd

zhbgvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbgvd(JOBZ, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, W, Z, LDZ, WORK,
                  LWORK, RWORK, LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhbgvd_(const char *jobz, const char *uplo, const armpl_int_t *n,
             const armpl_int_t *ka, const armpl_int_t *kb,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             armpl_doublecomplex_t *bb, const armpl_int_t *ldbb, double *w,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             double *rwork, const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is COMPLEX*16

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^H *S, as returned by ZPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z^H *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= N. If JOBZ = 'V' and N > 1, LWORK >= 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO=0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK >= 1. If JOBZ = 'N' and N > 1, LRWORK >= N. If JOBZ = 'V' and N > 1, LRWORK >= 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO=0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then ZPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chbgvd*. It also exists with a native C interface as *LAPACKE_zhbgvd*.

4.12.43 zhbgvx

zhbgvx computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbgvx(JOBZ, RANGE, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, Q, LDQ,
                  VL, VU, IL, IU, ABSTOL, M, W, Z, LDZ, WORK, RWORK, IWORK,
                  IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void zhbgvx_(const char *jobz, const char *range, const char *uplo,
             const armpl_int_t *n, const armpl_int_t *ka,
             const armpl_int_t *kb, armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, armpl_doublecomplex_t *bb,
             const armpl_int_t *ldbb, armpl_doublecomplex_t *q,
             const armpl_int_t *ldq, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
```

(continues on next page)

(continued from previous page)

```
                const double *abstol, armpl_int_t *m, double *w,
                armpl_doublecomplex_t *z, const armpl_int_t *ldz,
                armpl_doublecomplex_t *work, double *rwork, armpl_int_t *iwork,
                armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

KA Input parameter.

KA is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB Input parameter.

KB is INTEGER

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KA+1.

BB Input and output parameter.

BB is COMPLEX*16

BB is an array, dimension (LDBB, N). On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as

follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S^H *S, as returned by ZPBSTF.

LDBB Input parameter.

LDBB is INTEGER

The leading dimension of the array BB. LDBB >= KB+1.

Q Output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the n-by-n matrix used in the reduction of A*x = (lambda)*B*x to standard form, i.e. C*x = (lambda)*x, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z^H *B* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, and i is: <= N: then i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then ZPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chbgvx*. It also exists with a native C interface as *LAPACKE_zhbgvx*.

4.12.44 zhegst

zhegst reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^H or L^H *A*L.

B must have been previously factorized as U^H *U or L*L^H by ZPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhegst(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zhegst_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

= 1: compute inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H); = 2 or 3: compute U*A*U^H or L^H *A*L.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored and B is factored as U^H *U; = 'L': Lower triangle of A is stored and B is factored as L*L^H .

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). The triangular factor from the Cholesky factorization of B, as returned by ZPOTRF.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chegst*. It also exists with a native C interface as *LAPACKE_zhegst*.

4.12.45 zhegv

zhegv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhegv(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK, RWORK,
                 INFO)
```

C specification:

```
#include "armpl.h"

void zhegv_(const armpl_int_t *itype, const char *jobz, const char *uplo,
            const armpl_int_t *n, armpl_doublecomplex_t *a,
            const armpl_int_t *lda, armpl_doublecomplex_t *b,
            const armpl_int_t *ldb, double *w, armpl_doublecomplex_t *work,
            const armpl_int_t *lwork, double *rwork, armpl_int_t *info,
            ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B*Z = I; if ITYPE = 3, Z^H *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the Hermitian positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,2*N-1). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the blocksize for ZHETRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: ZPOTRF or ZHEEV returned an error code: <= N: if INFO = i, ZHEEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of

order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chegv*. It also exists with a native C interface as *LAPACKE_zhegv*.

4.12.46 zhegvd

zhegvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhegvd(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK, RWORK,
                  LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhegvd_(const armpl_int_t *itype, const char *jobz, const char *uplo,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, double *w, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork,
             const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B*Z = I; if ITYPE = 3, Z^H *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= N + 1. If JOBZ = 'V' and N > 1, LWORK >= 2* N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. If N <= 1, LRWORK >= 1. If JOBZ = 'N' and N > 1, LRWORK >= N. If JOBZ = 'V' and N > 1, LRWORK >= 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK >= 1. If JOBZ = 'N' and N > 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: ZPOTRF or ZHEEVD returned an error code: <= N: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1); > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chegvd*. It also exists with a native C interface as *LAPACKE_zhegvd*.

4.12.47 zhegvx

zhegvx computes selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhegvx(ITYPE, JOBZ, RANGE, UPLO, N, A, LDA, B, LDB, VL, VU, IL, IU,
                  ABSTOL, M, W, Z, LDZ, WORK, LWORK, RWORK, IWORK, IFAIL,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zhegvx_(const armpl_int_t *itype, const char *jobz, const char *range,
             const char *uplo, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, const double *vl, const double *vu,
             const armpl_int_t *il, const armpl_int_t *iu,
             const double *abstol, armpl_int_t *m, double *w,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             double *rwork, armpl_int_t *iwork, armpl_int_t *ifail,
             armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing C to tridiagonal form, where C is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B* Z = I; if ITYPE = 3, Z^T *inv(B)* Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1,2*N). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the blocksize for ZHETRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: ZPOTRF or ZHEEVX returned an error code: <= N: if INFO = i, ZHEEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chegvx*. It also exists with a native C interface as *LAPACKE_zhegvx*.

4.12.48 zhpgst

`zhpgst` reduces a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^H or L^H *A*L.

B must have been previously factorized as U^H *U or L*L^H by ZPPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpgst(ITYPE, UPLO, N, AP, BP, INFO)
```

C specification:

```
#include "armpl.h"

void zhpgst_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, const armpl_doublecomplex_t *bp,
             armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

`ITYPE` is `INTEGER`

= 1: compute inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H); = 2 or 3: compute U*A*U^H or L^H *A*L.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= '`U`': Upper triangle of A is stored and B is factored as U^H *U; = '`L`': Lower triangle of A is stored and B is factored as L*L^H .

N Input parameter.

`N` is `INTEGER`

The order of the matrices A and B. `N` >= 0.

AP Input and output parameter.

`AP` is `COMPLEX*16`

`AP` is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array `AP` as follows: if `UPLO` = '`U`', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if `UPLO` = '`L`', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, if `INFO` = 0, the transformed matrix, stored in the same format as A.

BP Input parameter.

`BP` is `COMPLEX*16`

`BP` is an array, dimension (N*(N+1)/2). The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by ZPPTRF.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chpgst*. It also exists with a native C interface as *LAPACKE_zhpgst*.

4.12.49 zhpgv

zhpgv computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpgv(ITYPE, JOBZ, UPLO, N, AP, BP, W, Z, LDZ, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhpgv_(const armpl_int_t *itype, const char *jobz, const char *uplo,
            const armpl_int_t *n, armpl_doublecomplex_t *ap,
            armpl_doublecomplex_t *bp, double *w, armpl_doublecomplex_t *z,
            const armpl_int_t *ldz, armpl_doublecomplex_t *work,
            double *rwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is COMPLEX*16

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H , in the same storage format as B.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B* Z = I; if ITYPE = 3, Z^H *inv(B)* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (max(1, 2*N-1)) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: ZPPTRF or ZHPEV returned an error code: <= N: if INFO = i, ZHPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chpgv*. It also exists with a native C interface as *LAPACKE_zhpgv*.

4.12.50 zhpgvd

`zhpgvd` computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpgvd(ITYPE, JOBZ, UPLO, N, AP, BP, W, Z, LDZ, WORK, LWORK, RWORK,
                  LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhpgvd_(const armpl_int_t *itype, const char *jobz, const char *uplo,
             const armpl_int_t *n, armpl_doublecomplex_t *ap,
             armpl_doublecomplex_t *bp, double *w, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork,
             const armpl_int_t *lrwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

`ITYPE` is `INTEGER`

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

`JOBZ` is `CHARACTER*1`

= '`N`': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= '`U`': Upper triangles of A and B are stored; = '`L`': Lower triangles of A and B are stored.

N Input parameter.

`N` is `INTEGER`

The order of the matrices A and B. `N` >= 0.

AP Input and output parameter.

`AP` is `COMPLEX*16`

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is COMPLEX*16

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H , in the same storage format as B.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B* Z = I; if ITYPE = 3, Z^H *inv(B)* Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the required LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= N. If JOBZ = 'V' and N > 1, LWORK >= 2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the required LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK >= 1. If JOBZ = 'N' and N > 1, LRWORK >= N. If JOBZ = 'V' and N > 1, LRWORK >= 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the required LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the required sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: ZPPTRF or ZHPEVD returned an error code: <= N: if INFO = i, ZHPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chpgvd*. It also exists with a native C interface as *LAPACKE_zhpgvd*.

4.12.51 zhpgvx

zhpgvx computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpgvx(ITYPE, JOBZ, RANGE, UPLO, N, AP, BP, VL, VU, IL, IU, ABSTOL,
                  M, W, Z, LDZ, WORK, RWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void zhpgvx_(const armpl_int_t *itype, const char *jobz, const char *range,
             const char *uplo, const armpl_int_t *n,
             armpl_doublecomplex_t *ap, armpl_doublecomplex_t *bp,
             const double *vl, const double *vu, const armpl_int_t *il,
             const armpl_int_t *iu, const double *abstol, armpl_int_t *m,
             double *w, armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *iwork,
             armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

AP Input and output parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP Input and output parameter.

BP is COMPLEX*16

BP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H , in the same storage format as B.

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B* Z = I; if ITYPE = 3, Z^H *inv(B)* Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: ZPPTRF or ZHPEVX returned an error code: <= N: if INFO = i, ZHPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chpgvx*. It also exists with a native C interface as *LAPACKE_zhpgvx*.

4.12.52 zpbstf

zpbstf computes a split Cholesky factorization of a complex Hermitian positive definite band matrix A.

This routine is designed to be used in conjunction with ZHBGST.

The factorization has the form A = S^H *S where S is a band matrix of the same bandwidth as A and the following structure:

```
S = ( U    )
    ( M  L )
```

where U is upper triangular of order m = (n+kd)/2, and L is lower triangular of order n-m.

Syntax

Fortran specification:

```
use armpl_library

subroutine zpbstf(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void zpbstf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the factor S from the split Cholesky factorization A = S^H *S. See Further Details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

Related Information

For this routine in other precisions, please see *cpbstf*, *dpbstf* and *spbstf*. It also exists with a native C interface as *LAPACKE_zpbstf*.

4.13 LAPACK non symmetric eigenvalues routines

4.13.1 cgebak

cgebak forms the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgebak(JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
```

C specification:

```
#include "armpl.h"

void cgebak_(const char *job, const char *side, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             const float *scale, const armpl_int_t *m,
             armpl_singlecomplex_t *v, const armpl_int_t *ldv,
             armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to CGEBAL.

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': V contains right eigenvectors; = 'L': V contains left eigenvectors.

N Input parameter.

N is INTEGER

The number of rows of the matrix V. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

The integers ILO and IHI determined by CGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

SCALE Input parameter.

SCALE is REAL

SCALE is an array, dimension (N). Details of the permutation and scaling factors, as returned by CGEBAL.

M Input parameter.

M is INTEGER

The number of columns of the matrix V. M >= 0.

V Input and output parameter.

V is COMPLEX

V is an array, dimension (LDV, M). On entry, the matrix of right or left eigenvectors to be transformed, as returned by CHSEIN or CTREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgebak*, *sgebak* and *zgebak*. It also exists with a native C interface as *LAPACKE_cgebak*.

4.13.2 cgebal

cgebal balances a general complex matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgebal(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

C specification:

```
#include "armpl.h"

void cgebal_(const char *job, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ilo, armpl_int_t *ihi,
             float *scale, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the operations to be performed on A: = 'N': none: simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

SCALE Output parameter.

SCALE is REAL

SCALE is an array, dimension (N). Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgebal*, *sgebal* and *zgebal*. It also exists with a native C interface as *LAPACKE_cgebal*.

4.13.3 cgees

cgees computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z^H).

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A complex matrix is in Schur form if it is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgees(JOBVS, SORT, SELECT, N, A, LDA, SDIM, W, VS, LDVS, WORK,
                 LWORK, RWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgees_(const char *jobvs, const char *sort, ARMPL_CGEES_SELECT select,
            const armpl_int_t *n, armpl_singlecomplex_t *a,
            const armpl_int_t *lda, armpl_int_t *sdim,
```

(continues on next page)

(continued from previous page)

```
            armpl_singlecomplex_t *w, armpl_singlecomplex_t *vs,
            const armpl_int_t *ldvs, armpl_singlecomplex_t *work,
            const armpl_int_t *lwork, float *rwork, armpl_int_t *bwork,
            armpl_int_t *info, ... );
```

Parameters

JOBVS Input parameter.

JOBVS is CHARACTER*1

= 'N': Schur vectors are not computed; = 'V': Schur vectors are computed.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered: = 'S': Eigenvalues are ordered (see SELECT).

SELECT Input parameter.

SELECT is a LOGICAL FUNCTION of one COMPLEX argument

SELECT must be declared EXTERNAL in the calling subroutine. If SORT = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. IF SORT = 'N', SELECT is not referenced. The eigenvalue W(j) is selected if SELECT(W(j)) is true.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten by its Schur form T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues for which SELECT is true.

W Output parameter.

W is COMPLEX

W is an array, dimension (N). W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

VS Output parameter.

VS is COMPLEX

VS is an array, dimension (LDVS, N). If JOBVS = 'V', VS contains the unitary matrix Z of Schur vectors. If JOBVS = 'N', VS is not referenced.

LDVS Input parameter.

LDVS is INTEGER

The leading dimension of the array VS. LDVS >= 1; if JOBVS = 'V', LDVS >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBVS = 'V', VS contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT = .TRUE.. This could also be caused by underflow due to scaling.

Related Information

For this routine in other precisions, please see *dgees*, *sgees* and *zgees*. It also exists with a native C interface as *LAPACKE_cgees*.

4.13.4 cgeesx

cgeesx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z^H).

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A complex matrix is in Schur form if it is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeesx(JOBVS, SORT, SELECT, SENSE, N, A, LDA, SDIM, W, VS, LDVS,
                  RCONDE, RCONDV, WORK, LWORK, RWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeesx_(const char *jobvs, const char *sort, ARMPL_CGEESX_SELECT select,
             const char *sense, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *sdim, armpl_singlecomplex_t *w,
             armpl_singlecomplex_t *vs, const armpl_int_t *ldvs,
             float *rconde, float *rcondv, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork, armpl_int_t *bwork,
             armpl_int_t *info, ... );
```

Parameters

JOBVS Input parameter.

JOBVS is CHARACTER*1

= 'N': Schur vectors are not computed; = 'V': Schur vectors are computed.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELECT).

SELECT Input parameter.

SELECT is a LOGICAL FUNCTION of one COMPLEX argument

SELECT must be declared EXTERNAL in the calling subroutine. If SORT = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORT = 'N', SELECT is not referenced. An eigenvalue W(j) is selected if SELECT(W(j)) is true.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': None are computed; = 'E': Computed for average of selected eigenvalues only; = 'V': Computed for selected right invariant subspace only; = 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORT must equal 'S'.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A is overwritten by its Schur form T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues for which SELECT is true.

W Output parameter.

W is COMPLEX

W is an array, dimension (N). W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

VS Output parameter.

VS is COMPLEX

VS is an array, dimension (LDVS, N). If JOBVS = 'V', VS contains the unitary matrix Z of Schur vectors. If JOBVS = 'N', VS is not referenced.

LDVS Input parameter.

LDVS is INTEGER

The leading dimension of the array VS. LDVS >= 1, and if JOBVS = 'V', LDVS >= N.

RCONDE Output parameter.

RCONDE is REAL

If SENSE = 'E' or 'B', RCONDE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV Output parameter.

RCONDV is REAL

If SENSE = 'V' or 'B', RCONDV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). Also, if SENSE = 'E' or 'V' or 'B', LWORK >= 2*SDIM*(N-SDIM), where SDIM is the number of selected eigenvalues computed by this routine. Note that 2*SDIM*(N-SDIM) <= N*N/2. Note also that an error is only returned if LWORK < max(1,2*N), but if SENSE = 'E' or 'V' or 'B' this may not be large enough. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates upper bound on the optimal size of the array WORK, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBVS = 'V', VS contains the transformation which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

Related Information

For this routine in other precisions, please see *dgeesx*, *sgeesx* and *zgeesx*. It also exists with a native C interface as *LAPACKE_cgeesx*.

4.13.5 cgeev

cgeev computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector v(j) of A satisfies

```
A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue. The left eigenvector u(j) of A satisfies

```
u(j)**H * A = lambda(j) * u(j)**H
```

where $u(j)^H$ denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeev(JOBVL, JOBVR, N, A, LDA, W, VL, LDVL, VR, LDVR, WORK, LWORK,
                 RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeev_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
            armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *w, armpl_singlecomplex_t *vl,
            const armpl_int_t *ldvl, armpl_singlecomplex_t *vr,
            const armpl_int_t *ldvr, armpl_singlecomplex_t *work,
            const armpl_int_t *lwork, float *rwork, armpl_int_t *info, ... );
```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': left eigenvectors of A are not computed; = 'V': left eigenvectors of are computed.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': right eigenvectors of A are not computed; = 'V': right eigenvectors of A are computed.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is COMPLEX

W is an array, dimension (N). W contains the computed eigenvalues.

VL Output parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. u(j) = VL(:,j), the j-th column of VL.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. v(j) = VR(:,j), the j-th column of VR.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements and i+1:N of W contain eigenvalues which have converged.

Related Information

For this routine in other precisions, please see *dgeev*, *sgeev* and *zgeev*. It also exists with a native C interface as *LAPACKE_cgeev*.

4.13.6 cgeevx

cgeevx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector v(j) of A satisfies

```
A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue. The left eigenvector u(j) of A satisfies

```
u(j)**H * A = lambda(j) * u(j)**H
```

where $u(j)^H$ denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation D * A * D**(-1), where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeevx(BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, W, VL, LDVL, VR,
                  LDVR, ILO, IHI, SCALE, ABNRM, RCONDE, RCONDV, WORK, LWORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeevx_(const char *balanc, const char *jobvl, const char *jobvr,
             const char *sense, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *w, armpl_singlecomplex_t *vl,
             const armpl_int_t *ldvl, armpl_singlecomplex_t *vr,
             const armpl_int_t *ldvr, armpl_int_t *ilo, armpl_int_t *ihi,
             float *scale, float *abnrm, float *rconde, float *rcondv,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

BALANC Input parameter.

BALANC is CHARACTER*1

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute; = 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, ie. replace A by D*A*D**(-1), where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': left eigenvectors of A are not computed; = 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': right eigenvectors of A are not computed; = 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': None are computed; = 'E': Computed for eigenvalues only; = 'V': Computed for right eigenvectors only; = 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the Schur form of the balanced version of the matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is COMPLEX

W is an array, dimension (N). W contains the computed eigenvalues.

VL Output parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. u(j) = VL(:,j), the j-th column of VL.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. v(j) = VR(:,j), the j-th column of VR.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; if JOBVR = 'V', LDVR >= N.

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE Output parameter.

SCALE is REAL

SCALE is an array, dimension (N). Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM Output parameter.

ABNRM is REAL

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONDE Output parameter.

RCONDE is REAL

RCONDE is an array, dimension (N). RCONDE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONDV Output parameter.

RCONDV is REAL

RCONDV is an array, dimension (N). RCONDV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SENSE = 'N' or 'E', LWORK >= max(1,2*N), and if SENSE = 'V' or 'B', LWORK >= N*N+2*N. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of W contain eigenvalues which have converged.

Related Information

For this routine in other precisions, please see *dgeevx*, *sgeevx* and *zgeevx*. It also exists with a native C interface as *LAPACKE_cgeevx*.

4.13.7 cgehrd

cgehrd reduces a complex general matrix A to upper Hessenberg form H by an unitary similarity transformation: $Q^H * A * Q = H$.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgehrd(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgehrd_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL; otherwise they should be set to 1 and N respectively. See Further Details. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1, N). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgehrd*, *sgehrd* and *zgehrd*. It also exists with a native C interface as *LAPACKE_cgehrd*.

4.13.8 chsein

chsein uses inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

```
H * x = w * x,      y**h * H = w * y**h
```

where y**h denotes the conjugate transpose of the vector y.

Syntax

Fortran specification:

```
use armpl_library

subroutine chsein(SIDE, EIGSRC, INITV, SELECT, N, H, LDH, W, VL, LDVL, VR,
                  LDVR, MM, M, WORK, RWORK, IFAILL, IFAILR, INFO)
```

C specification:

```
#include "armpl.h"

void chsein_(const char *side, const char *eigsrc, const char *initv,
             const armpl_int_t *select, const armpl_int_t *n,
             const armpl_singlecomplex_t *h, const armpl_int_t *ldh,
             armpl_singlecomplex_t *w, armpl_singlecomplex_t *vl,
             const armpl_int_t *ldvl, armpl_singlecomplex_t *vr,
             const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *ifaill,
             armpl_int_t *ifailr, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

EIGSRC Input parameter.

EIGSRC is CHARACTER*1

Specifies the source of eigenvalues supplied in W: = 'Q': the eigenvalues were found using CHSEQR; thus, if H has zero subdiagonal elements, and so is block-triangular, then the j-th eigenvalue can be assumed to be an eigenvalue of the block containing the j-th row/column. This property allows CHSEIN to perform

inverse iteration on just one diagonal block. = 'N': no assumptions are made on the correspondence between eigenvalues and diagonal blocks. In this case, CHSEIN must always perform inverse iteration using the whole matrix H.

INITV Input parameter.

INITV is CHARACTER*1

= 'N': no initial vectors are supplied; = 'U': user-supplied initial vectors are stored in the arrays VL and/or VR.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). Specifies the eigenvectors to be computed. To select the eigenvector corresponding to the eigenvalue W(j), SELECT(j) must be set to .TRUE..

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

H Input parameter.

H is COMPLEX

H is an array, dimension (LDH, N). The upper Hessenberg matrix H. If a NaN is detected in H, the routine will return with INFO=-6.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

W Input and output parameter.

W is COMPLEX

W is an array, dimension (N). On entry, the eigenvalues of H. On exit, the real parts of W may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

VL Input and output parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, MM). On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= max(1, N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR Input and output parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, MM). On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= max(1, N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR required to store the eigenvectors (= the number of .TRUE. elements in SELECT).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

IFAILL Output parameter.

IFAILL is INTEGER array, dimension (MM)

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'R', IFAILL is not referenced.

IFAILR Output parameter.

IFAILR is INTEGER array, dimension (MM)

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'L', IFAILR is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

Related Information

For this routine in other precisions, please see *dhsein*, *shsein* and *zhsein*. It also exists with a native C interface as *LAPACKE_chsein*.

4.13.9 chseqr

```
CHSEQR computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**H, where T is an upper triangular matrix (the
   Schur form), and Z is the unitary matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input unitary
```

(continues on next page)

(continued from previous page)

```
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the unitary matrix Q:  A = Q*H*Q**H = (QZ)*T*(QZ)**H.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine chseqr(JOB, COMPZ, N, ILO, IHI, H, LDH, W, Z, LDZ, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void chseqr_(const char *job, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             armpl_singlecomplex_t *h, const armpl_int_t *ldh,
             armpl_singlecomplex_t *w, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

= 'E': compute eigenvalues only; = 'S': compute eigenvalues and the Schur form T.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': no Schur vectors are computed; = 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = 'V': Z must contain an unitary matrix Q on entry, and the product Q* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL, and then passed to ZGEHRD when the matrix output by CGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is COMPLEX

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and JOB = 'S', H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If INFO = 0

and JOB = 'E', the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

Unlike earlier versions of CHSEQR, this subroutine may explicitly H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

W Output parameter.

W is COMPLEX

W is an array, dimension (N). The computed eigenvalues. If JOB = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with W(i) = H(i,i).

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If COMPZ = 'N', Z is not referenced. If COMPZ = 'I', on entry Z need not be set and on exit, if INFO = 0, Z contains the unitary matrix Z of the Schur vectors of H. If COMPZ = 'V', on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the submatrix Z(ILO:IHI,ILO:IHI). On exit, if INFO = 0, Z contains Q*Z. Normally Q is the unitary matrix generated by CUNGHR after the call to CGEHRD which formed the Hessenberg matrix H. (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if COMPZ = 'I' or COMPZ = 'V', then LDZ.GE.MAX(1, N). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient and delivers very good and sometimes optimal performance. However, LWORK as large as 11*N may be required for optimal performance. A workspace query is recommended to determine the optimal workspace size.

If LWORK = -1, then CHSEQR does a workspace query. In this case, CHSEQR checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .LT. 0: if INFO = -i, the i-th argument had an illegal value .GT. 0: if INFO = i, CHSEQR failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and JOB = 'E', then on exit, the remaining unconverged eigenvalues are the eigen- values of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and JOB = 'S', then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is a unitary matrix. The final value of `H` is upper Hessenberg and triangular in rows and columns INFO+1 through `IHI`.

If `INFO` .GT. 0 and `COMPZ` = 'V', then on exit

(final value of Z) = (initial value of Z)*U

where U is the unitary matrix in (*) (regard- less of the value of `JOB`.)

If `INFO` .GT. 0 and `COMPZ` = 'I', then on exit (final value of Z) = U where U is the unitary matrix in (*) (regard- less of the value of `JOB`.)

If `INFO` .GT. 0 and `COMPZ` = 'N', then `Z` is not accessed.

Related Information

4.13.10 ctrevc

`ctrevc` computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T. Matrices of this type are produced by the Schur factorization of a complex general matrix: A = Q*T*Q^H , as computed by CHSEQR.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
T*x = w*x,      (y**H)*T = w*(y**H)
```

where y^H denotes the conjugate transpose of the vector y. The eigenvalues are not input to this routine, but are read directly from the diagonal of T.

This routine returns the matrices X and/or Y of right and left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input matrix. If Q is the unitary factor that reduces a matrix A to Schur form T, then Q*X and Q*Y are the matrices of right and left eigenvectors of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrevc(SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, MM, M,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctrevc_(const char *side, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, armpl_singlecomplex_t *vl,
             const armpl_int_t *ldvl, armpl_singlecomplex_t *vr,
             const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed using the matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, as indicated by the logical array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. The eigenvector corresponding to the j-th eigenvalue is computed if SELECT(j) = .TRUE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). The upper triangular matrix T. T is modified, but restored on exit.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input and output parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1, and if SIDE = 'L' or 'B', LDVL >= N.

VR Input and output parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B'; LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrevc*, *strevc* and *ztrevc*. It also exists with a native C interface as *LAPACKE_ctrevc*.

4.13.11 ctrexc

ctrexc reorders the Schur factorization of a complex matrix A = Q*T*Q^H , so that the diagonal element of T with row index IFST is moved to row ILST.

The Schur form T is reordered by a unitary similarity transformation Z^H *T*Z, and optionally the matrix Q of Schur vectors is updated by postmultplying it with Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrexc(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)
```

C specification:

```
#include "armpl.h"

void ctrexc_(const char *compq, const armpl_int_t *n,
             armpl_singlecomplex_t *t, const armpl_int_t *ldt,
             armpl_singlecomplex_t *q, const armpl_int_t *ldq,
```

(continues on next page)

(continued from previous page)

```
            const armpl_int_t *ifst, const armpl_int_t *ilst,
            armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'V': update the matrix Q of Schur vectors; = 'N': do not update Q.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0. If N == 0 arguments ILST and IFST may be any value.

T Input and output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). On entry, the upper triangular matrix T. On exit, the reordered upper triangular matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix Z which reorders T. If COMPQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1, and if COMPQ = 'V', LDQ >= max(1, N).

IFST Input parameter.

IFST is INTEGER

ILST Input parameter.

ILST is INTEGER

Specify the reordering of the diagonal elements of T: The element with row index IFST is moved to row ILST by a sequence of transpositions between adjacent elements. 1 <= IFST <= N; 1 <= ILST <= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrexc*, *strexc* and *ztrexc*. It also exists with a native C interface as *LAPACKE_ctrexc*.

4.13.12 ctrsen

`ctrsen` reorders the Schur factorization of a complex matrix A = Q*T*Q^H , so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrsen(JOB, COMPQ, SELECT, N, T, LDT, Q, LDQ, W, M, S, SEP, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctrsen_(const char *job, const char *compq, const armpl_int_t *select,
             const armpl_int_t *n, armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, armpl_singlecomplex_t *q,
             const armpl_int_t *ldq, armpl_singlecomplex_t *w, armpl_int_t *m,
             float *s, float *sep, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP): = 'N': none; = 'E': for eigenvalues only (S); = 'V': for invariant subspace only (SEP); = 'B': for both eigenvalues and invariant subspace (S and SEP).

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'V': update the matrix Q of Schur vectors; = 'N': do not update Q.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). SELECT specifies the eigenvalues in the selected cluster. To select the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). On entry, the upper triangular matrix T. On exit, T is overwritten by the reordered matrix T, with the selected eigenvalues as the leading diagonal elements.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; and if COMPQ = 'V', LDQ >= N.

W Output parameter.

W is COMPLEX

W is an array, dimension (N). The reordered eigenvalues of T, in the same order as they appear on the diagonal of T.

M Output parameter.

M is INTEGER

The dimension of the specified invariant subspace. 0 <= M <= N.

S Output parameter.

S is REAL

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of sqrt(N). If M = 0 or N, S = 1. If JOB = 'N' or 'V', S is not referenced.

SEP Output parameter.

SEP is REAL

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If M = 0 or N, SEP = norm(T). If JOB = 'N' or 'E', SEP is not referenced.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOB = 'N', LWORK >= 1; if JOB = 'E', LWORK = max(1,M*(N-M)); if JOB = 'V' or 'B', LWORK >= max(1,2*M*(N-M)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrsen*, *strsen* and *ztrsen*. It also exists with a native C interface as *LAPACKE_ctrsen*.

4.13.13 ctrsna

`ctrsna` estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix Q*T*Q^H with Q unitary).

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrsna(JOB, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, S, SEP,
                  MM, M, WORK, LDWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctrsna_(const char *job, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, const armpl_singlecomplex_t *vl,
             const armpl_int_t *ldvl, const armpl_singlecomplex_t *vr,
             const armpl_int_t *ldvr, float *s, float *sep,
             const armpl_int_t *mm, armpl_int_t *m,
             armpl_singlecomplex_t *work, const armpl_int_t *ldwork,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

`JOB` is `CHARACTER*1`

Specifies whether condition numbers are required for eigenvalues (`S`) or eigenvectors (`SEP`): = 'E': for eigenvalues only (`S`); = 'V': for eigenvectors only (`SEP`); = 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY Input parameter.

`HOWMNY` is `CHARACTER*1`

= 'A': compute condition numbers for all eigenpairs; = 'S': compute condition numbers for selected eigenpairs specified by the array `SELECT`.

SELECT Input parameter.

`SELECT` is `LOGICAL`

`SELECT` is an array, dimension (`N`). If `HOWMNY` = 'S', `SELECT` specifies the eigenpairs for which condition numbers are required. To select condition numbers for the j-th eigenpair, SELECT(j) must be set to .TRUE.. If `HOWMNY` = 'A', `SELECT` is not referenced.

N Input parameter.

`N` is `INTEGER`

The order of the matrix `T`. `N` >= 0.

T Input parameter.

T is COMPLEX

T is an array, dimension (LDT, N). The upper triangular matrix T.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, M). If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any Q*T*Q^H with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CHSEIN or CTREVC. If JOB = 'V', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; and if JOB = 'E' or 'B', LDVL >= N.

VR Input parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, M). If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any Q*T*Q^H with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CHSEIN or CTREVC. If JOB = 'V', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; and if JOB = 'E' or 'B', LDVR >= N.

S Output parameter.

S is REAL

S is an array, dimension (MM). If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP Output parameter.

SEP is REAL

SEP is an array, dimension (MM). If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If JOB = 'E', SEP is not referenced.

MM Input parameter.

MM is INTEGER

The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M Output parameter.

M is INTEGER

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LDWORK,N+6). If JOB = 'E', WORK is not referenced.

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N). If JOB = 'E', RWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrsna*, *strsna* and *ztrsna*. It also exists with a native C interface as *LAPACKE_ctrsna*.

4.13.14 ctrsyl

ctrsyl solves the complex Sylvester matrix equation:

```
op(A)*X + X*op(B) = scale*C or
op(A)*X - X*op(B) = scale*C,
```

where op(A) = A or A^H , and A and B are both upper triangular. A is M-by-M and B is N-by-N; the right hand side C and the solution X are M-by-N; and scale is an output scale factor, set <= 1 to avoid overflow in X.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrsyl(TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC, SCALE,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ctrsyl_(const char *trana, const char *tranb, const armpl_int_t *isgn,
             const armpl_int_t *m, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *c, const armpl_int_t *ldc, float *scale,
             armpl_int_t *info, ... );
```

Parameters

TRANA Input parameter.

TRANA is CHARACTER*1

Specifies the option op(A): = 'N': op(A) = A (No transpose) = 'C': op(A) = A^H (Conjugate transpose)

TRANB Input parameter.

TRANB is CHARACTER*1

Specifies the option op(B): = 'N': op(B) = B (No transpose) = 'C': op(B) = B^H (Conjugate transpose)

ISGN Input parameter.

ISGN is INTEGER

Specifies the sign in the equation: = +1: solve op(A)*X + X*op(B) = scale*C = -1: solve op(A)*X - X*op(B) = scale* C

M Input parameter.

M is INTEGER

The order of the matrix A, and the number of rows in the matrices X and C. M >= 0.

N Input parameter.

N is INTEGER

The order of the matrix B, and the number of columns in the matrices X and C. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, M). The upper triangular matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, N). The upper triangular matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N right hand side matrix C. On exit, C is overwritten by the solution matrix X.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M)

SCALE Output parameter.

SCALE is REAL

The scale factor, scale, set <= 1 to avoid overflow in X.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1: A and B have common or very close eigenvalues; perturbed values were used to solve the equation (but the matrices A and B are unchanged).

Related Information

For this routine in other precisions, please see *dtrsyl*, *strsyl* and *ztrsyl*. It also exists with a native C interface as *LAPACKE_ctrsyl*.

4.13.15 cunghr

cunghr generates a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine cunghr(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunghr_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by CGEHRD. On exit, the N-by-N unitary matrix Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEHRD.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= IHI-ILO. For optimum performance LWORK >= (IHI-ILO)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunghr*. It also exists with a native C interface as *LAPACKE_cunghr*.

4.13.16 cunmhr

cunmhr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by CGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine cunmhr(SIDE, TRANS, M, N, ILO, IHI, A, LDA, TAU, C, LDC, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cunmhr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, const armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *c, const armpl_int_t *ldc,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). If SIDE = 'L', then 1 <= ILO <= IHI <= M, if M > 0, and ILO = 1 and IHI = 0, if M = 0; if SIDE = 'R', then 1 <= ILO <= IHI <= N, if N > 0, and ILO = 1 and IHI = 0, if N = 0.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L' (LDA, N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CGEHRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M) if SIDE = 'L'; LDA >= max(1, N) if SIDE = 'R'.

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEHRD.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zunmhr*. It also exists with a native C interface as *LAPACKE_cunmhr*.

4.13.17 dgebak

dgebak forms the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by DGEBAL.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgebak(JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
```

C specification:

```
#include "armpl.h"

void dgebak_(const char *job, const char *side, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             const double *scale, const armpl_int_t *m, double *v,
             const armpl_int_t *ldv, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to DGEBAL.

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': V contains right eigenvectors; = 'L': V contains left eigenvectors.

N Input parameter.

N is INTEGER

The number of rows of the matrix V. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

The integers ILO and IHI determined by DGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

SCALE Input parameter.

SCALE is DOUBLE PRECISION

SCALE is an array, dimension (N). Details of the permutation and scaling factors, as returned by DGEBAL.

M Input parameter.

M is INTEGER

The number of columns of the matrix V. M >= 0.

V Input and output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, M). On entry, the matrix of right or left eigenvectors to be transformed, as returned by DHSEIN or DTREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebak*, *sgebak* and *zgebak*. It also exists with a native C interface as *LAPACKE_dgebak*.

4.13.18 dgebal

`dgebal` balances a general real matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgebal(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

C specification:

```
#include "armpl.h"

void dgebal_(const char *job, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *ilo, armpl_int_t *ihi,
             double *scale, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

`JOB` is `CHARACTER*1`

Specifies the operations to be performed on A: = 'N': none: simply set `ILO` = 1, `IHI` = `N`, SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). On entry, the input matrix `A`. On exit, `A` is overwritten by the balanced matrix. If `JOB` = 'N', `A` is not referenced. See Further Details.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `N`).

ILO Output parameter.

`ILO` is `INTEGER`

IHI Output parameter.

`IHI` is `INTEGER`

`ILO` and `IHI` are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N. If `JOB` = 'N' or 'S', `ILO` = 1 and `IHI` = `N`.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

SCALE is an array, dimension (N). Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebal*, *sgebal* and *zgebal*. It also exists with a native C interface as *LAPACKE_dgebal*.

4.13.19 dgees

dgees computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z^T).

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

```
[  a  b  ]
[  c  a  ]
```

where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

Syntax

Fortran specification:

```
use armpl_library

subroutine dgees(JOBVS, SORT, SELECT, N, A, LDA, SDIM, WR, WI, VS, LDVS, WORK,
                 LWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgees_(const char *jobvs, const char *sort, ARMPL_DGEES_SELECT select,
            const armpl_int_t *n, double *a, const armpl_int_t *lda,
            armpl_int_t *sdim, double *wr, double *wi, double *vs,
            const armpl_int_t *ldvs, double *work, const armpl_int_t *lwork,
            armpl_int_t *bwork, armpl_int_t *info, ... );
```

Parameters

JOBVS Input parameter.

JOBVS is CHARACTER*1

= 'N': Schur vectors are not computed; = 'V': Schur vectors are computed.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELECT).

SELECT Input parameter.

SELECT is a LOGICAL FUNCTION of two DOUBLE PRECISION arguments

SELECT must be declared EXTERNAL in the calling subroutine. If SORT = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORT = 'N', SELECT is not referenced. An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if SELECT(WR(j),WI(j)) is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO is set to N+2 (see INFO below).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten by its real Schur form T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR Output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (N) .

WI Output parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (N). WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

VS Output parameter.

VS is DOUBLE PRECISION

VS is an array, dimension (LDVS, N). If JOBVS = 'V', VS contains the orthogonal matrix Z of Schur vectors. If JOBVS = 'N', VS is not referenced.

LDVS Input parameter.

LDVS is INTEGER

The leading dimension of the array VS. LDVS >= 1; if JOBVS = 'V', LDVS >= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,3*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBVS = 'V', VS contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

Related Information

For this routine in other precisions, please see *cgees*, *sgees* and *zgees*. It also exists with a native C interface as *LAPACKE_dgees*.

4.13.20 dgeesx

dgeesx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z^T).

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A real matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

```
[  a  b  ]
[  c  a  ]
```

where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeesx(JOBVS, SORT, SELECT, SENSE, N, A, LDA, SDIM, WR, WI, VS,
                  LDVS, RCONDE, RCONDV, WORK, LWORK, IWORK, LIWORK, BWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgeesx_(const char *jobvs, const char *sort, ARMPL_DGEESX_SELECT select,
             const char *sense, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, armpl_int_t *sdim, double *wr,
             double *wi, double *vs, const armpl_int_t *ldvs, double *rconde,
             double *rcondv, double *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, const armpl_int_t *liwork,
             armpl_int_t *bwork, armpl_int_t *info, ... );
```

Parameters

JOBVS Input parameter.

JOBVS is CHARACTER*1

= 'N': Schur vectors are not computed; = 'V': Schur vectors are computed.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELECT).

SELECT Input parameter.

SELECT is a LOGICAL FUNCTION of two DOUBLE PRECISION arguments

SELECT must be declared EXTERNAL in the calling subroutine. If SORT = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORT = 'N', SELECT is not referenced. An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if SELECT(WR(j),WI(j)) is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both are. Note that a selected complex eigenvalue may no longer satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO may be set to N+3 (see INFO below).

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': None are computed; = 'E': Computed for average of selected eigenvalues only; = 'V': Computed for selected right invariant subspace only; = 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORT must equal 'S'.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A is overwritten by its real Schur form T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR Output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (N) .

WI Output parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (N). WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

VS Output parameter.

VS is DOUBLE PRECISION

VS is an array, dimension (LDVS, N). If JOBVS = 'V', VS contains the orthogonal matrix Z of Schur vectors. If JOBVS = 'N', VS is not referenced.

LDVS Input parameter.

LDVS is INTEGER

The leading dimension of the array VS. LDVS >= 1, and if JOBVS = 'V', LDVS >= N.

RCONDE Output parameter.

RCONDE is DOUBLE PRECISION

If SENSE = 'E' or 'B', RCONDE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV Output parameter.

RCONDV is DOUBLE PRECISION

If SENSE = 'V' or 'B', RCONDV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,3*N). Also, if SENSE = 'E' or 'V' or 'B', LWORK >= N+2*SDIM*(N-SDIM), where SDIM is the number of selected eigenvalues computed by this routine. Note

that N+2*SDIM*(N-SDIM) <= N+N*N/2. Note also that an error is only returned if LWORK < max(1,3*N), but if SENSE = 'E' or 'V' or 'B' this may not be large enough. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates upper bounds on the optimal sizes of the arrays WORK and IWORK, returns these values as the first entries of the WORK and IWORK arrays, and no error messages related to LWORK or LIWORK are issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= 1; if SENSE = 'V' or 'B', LIWORK >= SDIM*(N-SDIM). Note that SDIM*(N-SDIM) <= N*N/4. Note also that an error is only returned if LIWORK < 1, but if SENSE = 'V' or 'B' this may not be large enough.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates upper bounds on the optimal sizes of the arrays WORK and IWORK, returns these values as the first entries of the WORK and IWORK arrays, and no error messages related to LWORK or LIWORK are issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBVS = 'V', VS contains the transformation which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

Related Information

For this routine in other precisions, please see *cgeesx*, *sgeesx* and *zgeesx*. It also exists with a native C interface as *LAPACKE_dgeesx*.

4.13.21 dgeev

dgeev computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector v(j) of A satisfies

```
A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue. The left eigenvector u(j) of A satisfies

```
u(j)**H * A = lambda(j) * u(j)**H
```

where $u(j)^H$ denotes the conjugate-transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeev(JOBVL, JOBVR, N, A, LDA, WR, WI, VL, LDVL, VR, LDVR, WORK,
                 LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeev_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
            double *a, const armpl_int_t *lda, double *wr, double *wi,
            double *vl, const armpl_int_t *ldvl, double *vr,
            const armpl_int_t *ldvr, double *work, const armpl_int_t *lwork,
            armpl_int_t *info, ... );
```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': left eigenvectors of A are not computed; = 'V': left eigenvectors of A are computed.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': right eigenvectors of A are not computed; = 'V': right eigenvectors of A are computed.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

WR Output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (N) .

WI Output parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (N). WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

VL Output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,3*N), and if JOBVL = 'V' or JOBVR = 'V', LWORK >= 4*N. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements i+1:N of WR and WI contain eigenvalues which have converged.

Related Information

For this routine in other precisions, please see *cgeev*, *sgeev* and *zgeev*. It also exists with a native C interface as *LAPACKE_dgeev*.

4.13.22 dgeevx

dgeevx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector v(j) of A satisfies

```
A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue. The left eigenvector u(j) of A satisfies

```
u(j)**H * A = lambda(j) * u(j)**H
```

where $u(j)^H$ denotes the conjugate-transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation D * A * D**(-1), where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgeevx(BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, WR, WI, VL, LDVL,
                  VR, LDVR, ILO, IHI, SCALE, ABNRM, RCONDE, RCONDV, WORK,
                  LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgeevx_(const char *balanc, const char *jobvl, const char *jobvr,
             const char *sense, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *wr, double *wi, double *vl,
             const armpl_int_t *ldvl, double *vr, const armpl_int_t *ldvr,
             armpl_int_t *ilo, armpl_int_t *ihi, double *scale, double *abnrm,
             double *rconde, double *rcondv, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

BALANC Input parameter.

BALANC is CHARACTER*1

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute; = 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, i.e. replace A by D*A*D**(-1), where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': left eigenvectors of A are not computed; = 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': right eigenvectors of A are not computed; = 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': None are computed; = 'E': Computed for eigenvalues only; = 'V': Computed for right eigenvectors only; = 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the real Schur form of the balanced version of the input matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

WR Output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (N) .

WI Output parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (N). WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

VL Output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the

j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

SCALE is an array, dimension (N). Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM Output parameter.

ABNRM is DOUBLE PRECISION

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONDE Output parameter.

RCONDE is DOUBLE PRECISION

RCONDE is an array, dimension (N). RCONDE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONDV Output parameter.

RCONDV is DOUBLE PRECISION

RCONDV is an array, dimension (N). RCONDV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SENSE = 'N' or 'E', LWORK >= max(1,2*N), and if JOBVL = 'V' or JOBVR = 'V', LWORK >= 3*N. If SENSE = 'V' or 'B', LWORK >= N*(N+6). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (2*N-2)

If SENSE = 'N' or 'E', not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of WR and WI contain eigenvalues which have converged.

Related Information

For this routine in other precisions, please see *cgeevx*, *sgeevx* and *zgeevx*. It also exists with a native C interface as *LAPACKE_dgeevx*.

4.13.23 dgehrd

dgehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: $Q^T * A * Q = H$.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgehrd(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgehrd_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, double *a, const armpl_int_t *lda,
             double *tau, double *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to DGEBAL; otherwise they should be set to 1 and N respectively. See Further Details. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements

below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1, N). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgehrd*, *sgehrd* and *zgehrd*. It also exists with a native C interface as *LAPACKE_dgehrd*.

4.13.24 dhsein

dhsein uses inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

```
H * x = w * x,     y**h * H = w * y**h
```

where y**h denotes the conjugate transpose of the vector y.

Syntax

Fortran specification:

```
use armpl_library

subroutine dhsein(SIDE, EIGSRC, INITV, SELECT, N, H, LDH, WR, WI, VL, LDVL,
                  VR, LDVR, MM, M, WORK, IFAILL, IFAILR, INFO)
```

C specification:

```
#include "armpl.h"

void dhsein_(const char *side, const char *eigsrc, const char *initv,
             armpl_int_t *select, const armpl_int_t *n, const double *h,
             const armpl_int_t *ldh, double *wr, const double *wi, double *vl,
             const armpl_int_t *ldvl, double *vr, const armpl_int_t *ldvr,
             const armpl_int_t *mm, armpl_int_t *m, double *work,
             armpl_int_t *ifaill, armpl_int_t *ifailr, armpl_int_t *info,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

EIGSRC Input parameter.

EIGSRC is CHARACTER*1

Specifies the source of eigenvalues supplied in (WR, WI): = 'Q': the eigenvalues were found using DHSEQR; thus, if H has zero subdiagonal elements, and so is block-triangular, then the j-th eigenvalue can be assumed to be an eigenvalue of the block containing the j-th row/column. This property allows DHSEIN to perform inverse iteration on just one diagonal block. = 'N': no assumptions are made on the correspondence between eigenvalues and diagonal blocks. In this case, DHSEIN must always perform inverse iteration using the whole matrix H.

INITV Input parameter.

INITV is CHARACTER*1

= 'N': no initial vectors are supplied; = 'U': user-supplied initial vectors are stored in the arrays VL and/or VR.

SELECT Input and output parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). Specifies the eigenvectors to be computed. To select the real eigenvector corresponding to a real eigenvalue WR(j), SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex eigenvalue (WR(j),WI(j)), with complex conjugate (WR(j+1),WI(j+1)), either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; then on exit SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

H Input parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). The upper Hessenberg matrix H. If a NaN is detected in H, the routine will return with INFO=-6.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

WR Input and output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (N) .

WI Input parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (N). On entry, the real and imaginary parts of the eigenvalues of H; a complex conjugate pair of eigenvalues must be stored in consecutive elements of WR and WI. On exit, WR may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

VL Input and output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, MM). On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'R', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= max(1, N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR Input and output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, MM). On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= max(1, N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR required to store the eigenvectors; each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension ((N+2)*N) .

IFAILL Output parameter.

IFAILL is INTEGER array, dimension (MM)

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VL hold a complex eigenvector, then IFAILL(i) and IFAILL(i+1) are set to the same value. If SIDE = 'R', IFAILL is not referenced.

IFAILR Output parameter.

IFAILR is INTEGER array, dimension (MM)

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VR hold a complex eigenvector, then IFAILR(i) and IFAILR(i+1) are set to the same value. If SIDE = 'L', IFAILR is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

Related Information

For this routine in other precisions, please see *chsein*, *shsein* and *zhsein*. It also exists with a native C interface as *LAPACKE_dhsein*.

4.13.25 dhseqr

```
DHSEQR computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**T, where T is an upper quasi-triangular matrix (the
   Schur form), and Z is the orthogonal matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input orthogonal
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the orthogonal matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dhseqr(JOB, COMPZ, N, ILO, IHI, H, LDH, WR, WI, Z, LDZ, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dhseqr_(const char *job, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi, double *h,
             const armpl_int_t *ldh, double *wr, double *wi, double *z,
             const armpl_int_t *ldz, double *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

= 'E': compute eigenvalues only; = 'S': compute eigenvalues and the Schur form T.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': no Schur vectors are computed; = 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = 'V': Z must contain an orthogonal matrix Q on entry, and the product Q* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to DGEBAL, and then passed to ZGEHRD when the matrix output by DGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and JOB = 'S', then H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1).LT.0. If INFO = 0 and JOB = 'E', the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

Unlike earlier versions of DHSEQR, this subroutine may explicitly H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

WR Output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (N) .

WI Output parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (N). The real and imaginary parts, respectively, of the computed eigenvalues. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with WI(i) .GT. 0 and WI(i+1) .LT. 0. If JOB = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with WR(i) = H(i,i) and, if H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) = sqrt(-H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If COMPZ = 'N', Z is not referenced. If COMPZ = 'I', on entry Z need not be set and on exit, if INFO = 0, Z contains the orthogonal matrix Z of the Schur vectors of H. If COMPZ = 'V', on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the submatrix Z(ILO:IHI,ILO:IHI). On exit, if INFO = 0, Z contains Q*Z. Normally Q is the orthogonal matrix generated by DORGHR after the call to DGEHRD which formed the Hessenberg matrix H. (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if COMPZ = 'I' or COMPZ = 'V', then LDZ.GE.MAX(1, N). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient and delivers very good and sometimes optimal performance. However, LWORK as large as 11*N may be required for optimal performance. A workspace query is recommended to determine the optimal workspace size.

If LWORK = -1, then DHSEQR does a workspace query. In this case, DHSEQR checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .LT. 0: if INFO = -i, the i-th argument had an illegal value .GT. 0: if INFO = i, DHSEQR failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and JOB = 'E', then on exit, the remaining unconverged eigenvalues are the eigen- values of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and JOB = 'S', then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is an orthogonal matrix. The final value of H is upper Hessenberg and quasi-triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and COMPZ = 'V', then on exit

(final value of Z) = (initial value of Z)*U

where U is the orthogonal matrix in (*) (regard- less of the value of JOB.)

If INFO .GT. 0 and COMPZ = 'I', then on exit (final value of Z) = U where U is the orthogonal matrix in (*) (regard- less of the value of JOB.)

If INFO .GT. 0 and COMPZ = 'N', then Z is not accessed.

Related Information

For this routine in other precisions, please see *chseqr*, *shseqr* and *zhseqr*. It also exists with a native C interface as *LAPACKE_dhseqr*.

4.13.26 dorghr

`dorghr` generates a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by DGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine dorghr(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dorghr_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, double *a, const armpl_int_t *lda,
             const double *tau, double *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI must have the same values as in the previous call of DGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by DGEHRD. On exit, the N-by-N orthogonal matrix Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEHRD.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= IHI-ILO. For optimum performance LWORK >= (IHI-ILO)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sorghr*. It also exists with a native C interface as *LAPACKE_dorghr*.

4.13.27 dormhr

dormhr overwrites the general real M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by DGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine dormhr(SIDE, TRANS, M, N, ILO, IHI, A, LDA, TAU, C, LDC, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dormhr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *ilo,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *ihi, const double *a, const armpl_int_t *lda,
                const double *tau, double *c, const armpl_int_t *ldc,
                double *work, const armpl_int_t *lwork, armpl_int_t *info,
                ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI must have the same values as in the previous call of DGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). If SIDE = 'L', then 1 <= ILO <= IHI <= M, if M > 0, and ILO = 1 and IHI = 0, if M = 0; if SIDE = 'R', then 1 <= ILO <= IHI <= N, if N > 0, and ILO = 1 and IHI = 0, if N = 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension. (LDA, M) if SIDE = 'L' (LDA, N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by DGEHRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M) if SIDE = 'L'; LDA >= max(1, N) if SIDE = 'R'.

TAU Input parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by DGEHRD.

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *sormhr*. It also exists with a native C interface as *LAPACKE_dormhr*.

4.13.28 dtrevc

dtrevc computes some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T. Matrices of this type are produced by the Schur factorization of a real general matrix: A = Q*T*Q^T , as computed by DHSEQR.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
T*x = w*x,     (y**H)*T = w*(y**H)
```

where y^H denotes the conjugate transpose of y. The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of T.

This routine returns the matrices X and/or Y of right and left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input matrix. If Q is the orthogonal factor that reduces a matrix A to Schur form T, then Q*X and Q*Y are the matrices of right and left eigenvectors of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrevc(SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, MM, M,
                  WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtrevc_(const char *side, const char *howmny, armpl_int_t *select,
             const armpl_int_t *n, const double *t, const armpl_int_t *ldt,
             double *vl, const armpl_int_t *ldvl, double *vr,
             const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
             double *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed by the matrices in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, as indicated by the logical array SELECT.

SELECT Input and output parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If w(j) is a real eigenvalue, the corresponding real eigenvector is computed if SELECT(j) is .TRUE.. If w(j) and w(j+1) are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either SELECT(j) or SELECT(j+1) is .TRUE., and on exit SELECT(j) is set to .TRUE. and SELECT(j+1) is set to .FALSE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). The upper quasi-triangular matrix T in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input and output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by DHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1, and if SIDE = 'L' or 'B', LDVL >= N.

VR Input and output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by DHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrevc*, *strevc* and *ztrevc*. It also exists with a native C interface as *LAPACKE_dtrevc*.

4.13.29 dtrexc

dtrexc reorders the real Schur factorization of a real matrix A = Q*T*Q^T , so that the diagonal block of T with row index IFST is moved to row ILST.

The real Schur form T is reordered by an orthogonal similarity transformation Z^T *T*Z, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z.

T must be in Schur canonical form (as returned by DHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrexc(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtrexc_(const char *compq, const armpl_int_t *n, double *t,
             const armpl_int_t *ldt, double *q, const armpl_int_t *ldq,
             armpl_int_t *ifst, armpl_int_t *ilst, double *work,
             armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'V': update the matrix Q of Schur vectors; = 'N': do not update Q.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0. If N == 0 arguments ILST and IFST may be any value.

T Input and output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). On entry, the upper quasi-triangular matrix T, in Schur Schur canonical form. On exit, the reordered upper quasi-triangular matrix, again in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix Z which reorders T. If COMPQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1, and if COMPQ = 'V', LDQ >= max(1, N).

IFST Input and output parameter.

IFST is INTEGER

ILST Input and output parameter.

ILST is INTEGER

Specify the reordering of the diagonal blocks of T. The block with row index IFST is moved to row ILST, by a sequence of transpositions between adjacent blocks. On exit, if IFST pointed on entry to the second

row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST <= N; 1 <= ILST <= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1: two adjacent blocks were too close to swap (the problem is very ill-conditioned); T may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

Related Information

For this routine in other precisions, please see *ctrexc*, *strexc* and *ztrexc*. It also exists with a native C interface as *LAPACKE_dtrexc*.

4.13.30 dtrsen

dtrsen reorders the real Schur factorization of a real matrix A = Q*T*Q^T , so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur canonical form (as returned by DHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrsen(JOB, COMPQ, SELECT, N, T, LDT, Q, LDQ, WR, WI, M, S, SEP,
                  WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtrsen_(const char *job, const char *compq, const armpl_int_t *select,
             const armpl_int_t *n, double *t, const armpl_int_t *ldt,
             double *q, const armpl_int_t *ldq, double *wr, double *wi,
             armpl_int_t *m, double *s, double *sep, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP): = 'N': none; = 'E': for eigenvalues only (S); = 'V': for invariant subspace only (SEP); = 'B': for both eigenvalues and invariant subspace (S and SEP).

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'V': update the matrix Q of Schur vectors; = 'N': do not update Q.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select a complex conjugate pair of eigenvalues w(j) and w(j+1), corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). On entry, the upper quasi-triangular matrix T, in Schur canonical form. On exit, T is overwritten by the reordered matrix T, again in Schur canonical form, with the selected eigenvalues in the leading diagonal blocks.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; and if COMPQ = 'V', LDQ >= N.

WR Output parameter.

WR is DOUBLE PRECISION

WR is an array, dimension (N) .

WI Output parameter.

WI is DOUBLE PRECISION

WI is an array, dimension (N). The real and imaginary parts, respectively, of the reordered eigenvalues of T. The eigenvalues are stored in the same order as on the diagonal of T, with WR(i) = T(i,i) and, if T(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) > 0 and WI(i+1) = -WI(i). Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

M Output parameter.

M is INTEGER

The dimension of the specified invariant subspace. 0 < = M <= N.

S Output parameter.

S is DOUBLE PRECISION

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of sqrt(N). If M = 0 or N, S = 1. If JOB = 'N' or 'V', S is not referenced.

SEP Output parameter.

SEP is DOUBLE PRECISION

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If M = 0 or N, SEP = norm(T). If JOB = 'N' or 'E', SEP is not referenced.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOB = 'N', LWORK >= max(1, N); if JOB = 'E', LWORK >= max(1,M*(N-M)); if JOB = 'V' or 'B', LWORK >= max(1,2*M*(N-M)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOB = 'N' or 'E', LIWORK >= 1; if JOB = 'V' or 'B', LIWORK >= max(1,M*(N-M)).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1: reordering of T failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); T may have been partially reordered, and WR and WI contain the eigenvalues in the same order as in T; S and SEP (if requested) are set to zero.

Related Information

For this routine in other precisions, please see *ctrsen*, *strsen* and *ztrsen*. It also exists with a native C interface as *LAPACKE_dtrsen*.

4.13.31 dtrsna

dtrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix Q*T*Q^T with Q orthogonal).

T must be in Schur canonical form (as returned by DHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrsna(JOB, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, S, SEP,
                  MM, M, WORK, LDWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtrsna_(const char *job, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const double *t, const armpl_int_t *ldt,
             const double *vl, const armpl_int_t *ldvl, const double *vr,
             const armpl_int_t *ldvr, double *s, double *sep,
             const armpl_int_t *mm, armpl_int_t *m, double *work,
             const armpl_int_t *ldwork, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP): = 'E': for eigenvalues only (S); = 'V': for eigenvectors only (SEP); = 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute condition numbers for all eigenpairs; = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues w(j) and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). The upper quasi-triangular matrix T, in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, M). If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any Q*T*Q^T with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by DHSEIN or DTREVC. If JOB = 'V', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; and if JOB = 'E' or 'B', LDVL >= N.

VR Input parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, M). If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any Q*T*Q^T with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by DHSEIN or DTREVC. If JOB = 'V', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; and if JOB = 'E' or 'B', LDVR >= N.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (MM). If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP Output parameter.

SEP is DOUBLE PRECISION

SEP is an array, dimension (MM). If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of SEP are set to the same value. If the eigenvalues cannot be reordered to compute SEP(j), SEP(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', SEP is not referenced.

MM Input parameter.

MM is INTEGER

The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M Output parameter.

M is INTEGER

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LDWORK,N+6). If JOB = 'E', WORK is not referenced.

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

IWORK Output parameter.

IWORK is INTEGER array, dimension (2*(N-1))

If JOB = 'E', IWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrsna*, *strsna* and *ztrsna*. It also exists with a native C interface as *LAPACKE_dtrsna*.

4.13.32 dtrsyl

dtrsyl solves the real Sylvester matrix equation:

```
op(A)*X + X*op(B) = scale*C or
op(A)*X - X*op(B) = scale*C,
```

where op(A) = A or A^T , and A and B are both upper quasi- triangular. A is M-by-M and B is N-by-N; the right hand side C and the solution X are M-by-N; and scale is an output scale factor, set <= 1 to avoid overflow in X.

A and B must be in Schur canonical form (as returned by DHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrsyl(TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC, SCALE,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dtrsyl_(const char *trana, const char *tranb, const armpl_int_t *isgn,
             const armpl_int_t *m, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, const double *b, const armpl_int_t *ldb,
             double *c, const armpl_int_t *ldc, double *scale,
             armpl_int_t *info, ... );
```

Parameters

TRANA Input parameter.

TRANA is CHARACTER*1

Specifies the option op(A): = 'N': op(A) = A (No transpose) = 'T': op(A) = A^T (Transpose) = 'C': op(A) = A^H (Conjugate transpose = Transpose)

TRANB Input parameter.

TRANB is CHARACTER*1

Specifies the option op(B): = 'N': op(B) = B (No transpose) = 'T': op(B) = B^T (Transpose) = 'C': op(B) = B^H (Conjugate transpose = Transpose)

ISGN Input parameter.

ISGN is INTEGER

Specifies the sign in the equation: = +1: solve op(A)*X + X*op(B) = scale*C = -1: solve op(A)*X - X*op(B) = scale* C

M Input parameter.

M is INTEGER

The order of the matrix A, and the number of rows in the matrices X and C. M >= 0.

N Input parameter.

N is INTEGER

The order of the matrix B, and the number of columns in the matrices X and C. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, M). The upper quasi-triangular matrix A, in Schur canonical form.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). The upper quasi-triangular matrix B, in Schur canonical form.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, the M-by-N right hand side matrix C. On exit, C is overwritten by the solution matrix X.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M)

SCALE Output parameter.

SCALE is DOUBLE PRECISION

The scale factor, scale, set <= 1 to avoid overflow in X.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1: A and B have common or very close eigenvalues; perturbed values were used to solve the equation (but the matrices A and B are unchanged).

Related Information

For this routine in other precisions, please see *ctrsyl*, *strsyl* and *ztrsyl*. It also exists with a native C interface as *LAPACKE_dtrsyl*.

4.13.33 sgebak

sgebak forms the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgebak(JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
```

C specification:

```
#include "armpl.h"

void sgebak_(const char *job, const char *side, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             const float *scale, const armpl_int_t *m, float *v,
             const armpl_int_t *ldv, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to SGEBAL.

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': V contains right eigenvectors; = 'L': V contains left eigenvectors.

N Input parameter.

N is INTEGER

The number of rows of the matrix V. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

The integers ILO and IHI determined by SGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

SCALE Input parameter.

SCALE is REAL

SCALE is an array, dimension (N). Details of the permutation and scaling factors, as returned by SGEBAL.

M Input parameter.

M is INTEGER

The number of columns of the matrix V. M >= 0.

V Input and output parameter.

V is REAL

V is an array, dimension (LDV, M). On entry, the matrix of right or left eigenvectors to be transformed, as returned by SHSEIN or STREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebak*, *dgebak* and *zgebak*. It also exists with a native C interface as *LAPACKE_sgebak*.

4.13.34 sgebal

sgebal balances a general real matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgebal(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

C specification:

```
#include "armpl.h"

void sgebal_(const char *job, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *ilo, armpl_int_t *ihi,
             float *scale, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the operations to be performed on A: = 'N': none: simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

SCALE Output parameter.

SCALE is REAL

SCALE is an array, dimension (N). Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebal*, *dgebal* and *zgebal*. It also exists with a native C interface as *LAPACKE_sgebal*.

4.13.35 sgees

`sgees` computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z^T).

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

```
[  a  b  ]
[  c  a  ]
```

where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

Syntax

Fortran specification:

```
use armpl_library

subroutine sgees(JOBVS, SORT, SELECT, N, A, LDA, SDIM, WR, WI, VS, LDVS, WORK,
                 LWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgees_(const char *jobvs, const char *sort, ARMPL_SGEES_SELECT select,
            const armpl_int_t *n, float *a, const armpl_int_t *lda,
            armpl_int_t *sdim, float *wr, float *wi, float *vs,
            const armpl_int_t *ldvs, float *work, const armpl_int_t *lwork,
            armpl_int_t *bwork, armpl_int_t *info, ... );
```

Parameters

JOBVS Input parameter.

`JOBVS` is `CHARACTER*1`

= 'N': Schur vectors are not computed; = 'V': Schur vectors are computed.

SORT Input parameter.

`SORT` is `CHARACTER*1`

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELECT).

SELECT Input parameter.

`SELECT` is a `LOGICAL` FUNCTION of two `REAL` arguments

`SELECT` must be declared EXTERNAL in the calling subroutine. If `SORT` = 'S', `SELECT` is used to select eigenvalues to sort to the top left of the Schur form. If `SORT` = 'N', `SELECT` is not referenced. An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if SELECT(WR(j),WI(j)) is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case `INFO` is set to N+2 (see `INFO` below).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten by its real Schur form T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR Output parameter.

WR is REAL

WR is an array, dimension (N) .

WI Output parameter.

WI is REAL

WI is an array, dimension (N). WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

VS Output parameter.

VS is REAL

VS is an array, dimension (LDVS, N). If JOBVS = 'V', VS contains the orthogonal matrix Z of Schur vectors. If JOBVS = 'N', VS is not referenced.

LDVS Input parameter.

LDVS is INTEGER

The leading dimension of the array VS. LDVS >= 1; if JOBVS = 'V', LDVS >= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,3*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBVS = 'V', VS contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

Related Information

For this routine in other precisions, please see *cgees*, *dgees* and *zgees*. It also exists with a native C interface as *LAPACKE_sgees*.

4.13.36 sgeesx

sgeesx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z^T).

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A real matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

```
[  a  b  ]
[  c  a  ]
```

where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeesx(JOBVS, SORT, SELECT, SENSE, N, A, LDA, SDIM, WR, WI, VS,
                  LDVS, RCONDE, RCONDV, WORK, LWORK, IWORK, LIWORK, BWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgeesx_(const char *jobvs, const char *sort, ARMPL_SGEESX_SELECT select,
             const char *sense, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, armpl_int_t *sdim, float *wr, float *wi,
```

(continues on next page)

(continued from previous page)

```
                float *vs, const armpl_int_t *ldvs, float *rconde, float *rcondv,
                float *work, const armpl_int_t *lwork, armpl_int_t *iwork,
                const armpl_int_t *liwork, armpl_int_t *bwork, armpl_int_t *info,
                ... );
```

Parameters

JOBVS Input parameter.

JOBVS is CHARACTER*1

= 'N': Schur vectors are not computed; = 'V': Schur vectors are computed.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELECT).

SELECT Input parameter.

SELECT is a LOGICAL FUNCTION of two REAL arguments

SELECT must be declared EXTERNAL in the calling subroutine. If SORT = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORT = 'N', SELECT is not referenced. An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if SELECT(WR(j),WI(j)) is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both are. Note that a selected complex eigenvalue may no longer satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO may be set to N+3 (see INFO below).

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': None are computed; = 'E': Computed for average of selected eigenvalues only; = 'V': Computed for selected right invariant subspace only; = 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORT must equal 'S'.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A is overwritten by its real Schur form T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR Output parameter.

WR is REAL

WR is an array, dimension (N) .

WI Output parameter.

WI is REAL

WI is an array, dimension (N). WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

VS Output parameter.

VS is REAL

VS is an array, dimension (LDVS, N). If JOBVS = 'V', VS contains the orthogonal matrix Z of Schur vectors. If JOBVS = 'N', VS is not referenced.

LDVS Input parameter.

LDVS is INTEGER

The leading dimension of the array VS. LDVS >= 1, and if JOBVS = 'V', LDVS >= N.

RCONDE Output parameter.

RCONDE is REAL

If SENSE = 'E' or 'B', RCONDE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV Output parameter.

RCONDV is REAL

If SENSE = 'V' or 'B', RCONDV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,3*N). Also, if SENSE = 'E' or 'V' or 'B', LWORK >= N+2*SDIM*(N-SDIM), where SDIM is the number of selected eigenvalues computed by this routine. Note that N+2*SDIM*(N-SDIM) <= N+N*N/2. Note also that an error is only returned if LWORK < max(1,3*N), but if SENSE = 'E' or 'V' or 'B' this may not be large enough. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates upper bounds on the optimal sizes of the arrays WORK and IWORK, returns these values as the first entries of the WORK and IWORK arrays, and no error messages related to LWORK or LIWORK are issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= 1; if SENSE = 'V' or 'B', LIWORK >= SDIM*(N-SDIM). Note that SDIM*(N-SDIM) <= N*N/4. Note also that an error is only returned if LIWORK < 1, but if SENSE = 'V' or 'B' this may not be large enough.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates upper bounds on the optimal sizes of the arrays WORK and IWORK, returns these values as the first entries of the WORK and IWORK arrays, and no error messages related to LWORK or LIWORK are issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBVS = 'V', VS contains the transformation which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

Related Information

For this routine in other precisions, please see *cgeesx*, *dgeesx* and *zgeesx*. It also exists with a native C interface as *LAPACKE_sgeesx*.

4.13.37 sgeev

sgeev computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector v(j) of A satisfies

```
A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue. The left eigenvector u(j) of A satisfies

```
u(j)**H * A = lambda(j) * u(j)**H
```

where $u(j)^H$ denotes the conjugate-transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeev(JOBVL, JOBVR, N, A, LDA, WR, WI, VL, LDVL, VR, LDVR, WORK,
                 LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeev_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
            float *a, const armpl_int_t *lda, float *wr, float *wi, float *vl,
            const armpl_int_t *ldvl, float *vr, const armpl_int_t *ldvr,
            float *work, const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': left eigenvectors of A are not computed; = 'V': left eigenvectors of A are computed.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': right eigenvectors of A are not computed; = 'V': right eigenvectors of A are computed.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

WR Output parameter.

WR is REAL

WR is an array, dimension (N) .

WI Output parameter.

WI is REAL

WI is an array, dimension (N). WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

VL Output parameter.

VL is REAL

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is REAL

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,3*N), and if JOBVL = 'V' or JOBVR = 'V', LWORK >= 4*N. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements i+1:N of WR and WI contain eigenvalues which have converged.

Related Information

For this routine in other precisions, please see *cgeev*, *dgeev* and *zgeev*. It also exists with a native C interface as *LAPACKE_sgeev*.

4.13.38 sgeevx

sgeevx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector v(j) of A satisfies

```
A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue. The left eigenvector u(j) of A satisfies

```
u(j)**H * A = lambda(j) * u(j)**H
```

where $u(j)^H$ denotes the conjugate-transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation D * A * D**(-1), where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgeevx(BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, WR, WI, VL, LDVL,
                  VR, LDVR, ILO, IHI, SCALE, ABNRM, RCONDE, RCONDV, WORK,
                  LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgeevx_(const char *balanc, const char *jobvl, const char *jobvr,
             const char *sense, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *wr, float *wi, float *vl,
             const armpl_int_t *ldvl, float *vr, const armpl_int_t *ldvr,
             armpl_int_t *ilo, armpl_int_t *ihi, float *scale, float *abnrm,
             float *rconde, float *rcondv, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

BALANC Input parameter.

BALANC is CHARACTER*1

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute; = 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, i.e. replace A by D*A*D**(-1), where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': left eigenvectors of A are not computed; = 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': right eigenvectors of A are not computed; = 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': None are computed; = 'E': Computed for eigenvalues only; = 'V': Computed for right eigenvectors only; = 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the real Schur form of the balanced version of the input matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

WR Output parameter.

WR is REAL

WR is an array, dimension (N) .

WI Output parameter.

WI is REAL

WI is an array, dimension (N). WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

VL Output parameter.

VL is REAL

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is REAL

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,. . . ,ILO-1 or I = IHI+1,. . . ,N.

SCALE Output parameter.

SCALE is REAL

SCALE is an array, dimension (N). Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM Output parameter.

ABNRM is REAL

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONDE Output parameter.

RCONDE is REAL

RCONDE is an array, dimension (N). RCONDE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONDV Output parameter.

RCONDV is REAL

RCONDV is an array, dimension (N). RCONDV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SENSE = 'N' or 'E', LWORK >= max(1,2*N), and if JOBVL = 'V' or JOBVR = 'V', LWORK >= 3*N. If SENSE = 'V' or 'B', LWORK >= N*(N+6). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (2*N-2)

If SENSE = 'N' or 'E', not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of WR and WI contain eigenvalues which have converged.

4.13.39 sgehrd

sgehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: $Q^T * A * Q = H$.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgehrd(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgehrd_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, float *a, const armpl_int_t *lda,
             float *tau, float *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL; otherwise they should be set to 1 and N respectively. See Further Details. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1, N). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgehrd*, *dgehrd* and *zgehrd*. It also exists with a native C interface as *LAPACKE_sgehrd*.

4.13.40 shsein

shsein uses inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

```
H * x = w * x,      y**h * H = w * y**h
```

where y**h denotes the conjugate transpose of the vector y.

Syntax

Fortran specification:

```
use armpl_library

subroutine shsein(SIDE, EIGSRC, INITV, SELECT, N, H, LDH, WR, WI, VL, LDVL,
                  VR, LDVR, MM, M, WORK, IFAILL, IFAILR, INFO)
```

C specification:

```
#include "armpl.h"

void shsein_(const char *side, const char *eigsrc, const char *initv,
             armpl_int_t *select, const armpl_int_t *n, const float *h,
             const armpl_int_t *ldh, float *wr, const float *wi, float *vl,
             const armpl_int_t *ldvl, float *vr, const armpl_int_t *ldvr,
             const armpl_int_t *mm, armpl_int_t *m, float *work,
             armpl_int_t *ifaill, armpl_int_t *ifailr, armpl_int_t *info,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

EIGSRC Input parameter.

EIGSRC is CHARACTER*1

Specifies the source of eigenvalues supplied in (WR, WI): = 'Q': the eigenvalues were found using SHSEQR; thus, if H has zero subdiagonal elements, and so is block-triangular, then the j-th eigenvalue can be assumed to be an eigenvalue of the block containing the j-th row/column. This property allows SHSEIN to perform inverse iteration on just one diagonal block. = 'N': no assumptions are made on the correspondence between eigenvalues and diagonal blocks. In this case, SHSEIN must always perform inverse iteration using the whole matrix H.

INITV Input parameter.

INITV is CHARACTER*1

= 'N': no initial vectors are supplied; = 'U': user-supplied initial vectors are stored in the arrays VL and/or VR.

SELECT Input and output parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). Specifies the eigenvectors to be computed. To select the real eigenvector corresponding to a real eigenvalue WR(j), SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex eigenvalue (WR(j),WI(j)), with complex conjugate (WR(j+1),WI(j+1)), either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; then on exit SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

H Input parameter.

H is REAL

H is an array, dimension (LDH, N). The upper Hessenberg matrix H. If a NaN is detected in H, the routine will return with INFO=-6.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

WR Input and output parameter.

WR is REAL

WR is an array, dimension (N) .

WI Input parameter.

WI is REAL

WI is an array, dimension (N). On entry, the real and imaginary parts of the eigenvalues of H; a complex conjugate pair of eigenvalues must be stored in consecutive elements of WR and WI. On exit, WR may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

VL Input and output parameter.

VL is REAL

VL is an array, dimension (LDVL, MM). On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'R', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= max(1, N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR Input and output parameter.

VR is REAL

VR is an array, dimension (LDVR, MM). On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= max(1, N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR required to store the eigenvectors; each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension ((N+2)*N) .

IFAILL Output parameter.

IFAILL is INTEGER array, dimension (MM)

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VL hold a complex eigenvector, then IFAILL(i) and IFAILL(i+1) are set to the same value. If SIDE = 'R', IFAILL is not referenced.

IFAILR Output parameter.

IFAILR is INTEGER array, dimension (MM)

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VR hold a complex eigenvector, then IFAILR(i) and IFAILR(i+1) are set to the same value. If SIDE = 'L', IFAILR is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

Related Information

For this routine in other precisions, please see *chsein*, *dhsein* and *zhsein*. It also exists with a native C interface as *LAPACKE_shsein*.

4.13.41 shseqr

```
SHSEQR computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**T, where T is an upper quasi-triangular matrix (the
   Schur form), and Z is the orthogonal matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input orthogonal
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the orthogonal matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine shseqr(JOB, COMPZ, N, ILO, IHI, H, LDH, WR, WI, Z, LDZ, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void shseqr_(const char *job, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi, float *h,
             const armpl_int_t *ldh, float *wr, float *wi, float *z,
             const armpl_int_t *ldz, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

= ‘E’: compute eigenvalues only; = ‘S’: compute eigenvalues and the Schur form T.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= ‘N’: no Schur vectors are computed; = ‘I’: Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = ‘V’: Z must contain an orthogonal matrix Q on entry, and the product Q* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL, and then passed to ZGEHRD when the matrix output by SGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is REAL

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and JOB = 'S', then H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1).LT.0. If INFO = 0 and JOB = 'E', the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

Unlike earlier versions of SHSEQR, this subroutine may explicitly H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

WR Output parameter.

WR is REAL

WR is an array, dimension (N) .

WI Output parameter.

WI is REAL

WI is an array, dimension (N). The real and imaginary parts, respectively, of the computed eigenvalues. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with WI(i) .GT. 0 and WI(i+1) .LT. 0. If JOB = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with WR(i) = H(i,i) and, if H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) = sqrt(-H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If COMPZ = 'N', Z is not referenced. If COMPZ = 'I', on entry Z need not be set and on exit, if INFO = 0, Z contains the orthogonal matrix Z of the Schur vectors of H. If COMPZ = 'V', on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the submatrix Z(ILO:IHI,ILO:IHI). On exit, if INFO = 0, Z contains Q*Z. Normally Q is the orthogonal matrix generated by SORGHR after the call to SGEHRD which formed the Hessenberg matrix H. (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if COMPZ = 'I' or COMPZ = 'V', then LDZ.GE.MAX(1, N). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient and delivers very good and sometimes optimal performance. However, LWORK as large as 11*N may be required for optimal performance. A workspace query is recommended to determine the optimal workspace size.

If LWORK = -1, then SHSEQR does a workspace query. In this case, SHSEQR checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .LT. 0: if INFO = -i, the i-th argument had an illegal value .GT. 0: if INFO = i, SHSEQR failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and JOB = 'E', then on exit, the remaining unconverged eigenvalues are the eigen- values of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and JOB = 'S', then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is an orthogonal matrix. The final value of H is upper Hessenberg and quasi-triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and COMPZ = 'V', then on exit

(final value of Z) = (initial value of Z)*U

where U is the orthogonal matrix in (*) (regard- less of the value of JOB.)

If INFO .GT. 0 and COMPZ = 'I', then on exit (final value of Z) = U where U is the orthogonal matrix in (*) (regard- less of the value of JOB.)

If INFO .GT. 0 and COMPZ = 'N', then Z is not accessed.

Related Information

For this routine in other precisions, please see *chseqr*, *dhseqr* and *zhseqr*. It also exists with a native C interface as *LAPACKE_shseqr*.

4.13.42 sorghr

sorghr generates a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine sorghr(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sorghr_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, float *a, const armpl_int_t *lda,
             const float *tau, float *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by SGEHRD. On exit, the N-by-N orthogonal matrix Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Input parameter.

TAU is REAL

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEHRD.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= IHI-ILO. For optimum performance LWORK >= (IHI-ILO)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dorghr*. It also exists with a native C interface as *LAPACKE_sorghr*.

4.13.43 sormhr

`sormhr` overwrites the general real M-by-N matrix C with

```
SIDE = 'L'      SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'T': Q^T * C C * Q^T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by SGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine sormhr(SIDE, TRANS, M, N, ILO, IHI, A, LDA, TAU, C, LDC, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sormhr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, const float *a, const armpl_int_t *lda,
             const float *tau, float *c, const armpl_int_t *ldc, float *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'T': Transpose, apply Q^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). If SIDE = 'L', then 1 <= ILO <= IHI <= M, if M > 0, and ILO = 1 and IHI = 0, if M = 0; if SIDE = 'R', then 1 <= ILO <= IHI <= N, if N > 0, and ILO = 1 and IHI = 0, if N = 0.

A Input parameter.

A is REAL

A is an array, dimension. (LDA, M) if SIDE = 'L' (LDA, N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SGEHRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M) if SIDE = 'L'; LDA >= max(1, N) if SIDE = 'R'.

TAU Input parameter.

TAU is REAL

TAU is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEHRD.

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^T * C or C*Q^T or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dormhr*. It also exists with a native C interface as *LAPACKE_sormhr*.

4.13.44 strevc

strevc computes some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T. Matrices of this type are produced by the Schur factorization of a real general matrix: A = Q*T*Q^T , as computed by SHSEQR.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
T*x = w*x,      (y**H)*T = w*(y**H)
```

where y^H denotes the conjugate transpose of y. The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of T.

This routine returns the matrices X and/or Y of right and left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input matrix. If Q is the orthogonal factor that reduces a matrix A to Schur form T, then Q*X and Q*Y are the matrices of right and left eigenvectors of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine strevc(SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, MM, M,
                  WORK, INFO)
```

C specification:

```
#include "armpl.h"

void strevc_(const char *side, const char *howmny, armpl_int_t *select,
             const armpl_int_t *n, const float *t, const armpl_int_t *ldt,
             float *vl, const armpl_int_t *ldvl, float *vr,
             const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
             float *work, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed by the matrices in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, as indicated by the logical array SELECT.

SELECT Input and output parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If w(j) is a real eigenvalue, the corresponding real eigenvector is computed if SELECT(j) is .TRUE.. If w(j) and w(j+1) are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either SELECT(j) or SELECT(j+1) is .TRUE., and on exit SELECT(j) is set to .TRUE. and SELECT(j+1) is set to .FALSE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input parameter.

T is REAL

T is an array, dimension (LDT, N). The upper quasi-triangular matrix T in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input and output parameter.

VL is REAL

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1, and if SIDE = 'L' or 'B', LDVL >= N.

VR Input and output parameter.

VR is REAL

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrevc*, *dtrevc* and *ztrevc*. It also exists with a native C interface as *LAPACKE_strevc*.

4.13.45 strexc

strexc reorders the real Schur factorization of a real matrix A = Q*T*Q^T , so that the diagonal block of T with row index IFST is moved to row ILST.

The real Schur form T is reordered by an orthogonal similarity transformation Z^T *T*Z, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine strexc(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void strexc_(const char *compq, const armpl_int_t *n, float *t,
             const armpl_int_t *ldt, float *q, const armpl_int_t *ldq,
             armpl_int_t *ifst, armpl_int_t *ilst, float *work,
             armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'V': update the matrix Q of Schur vectors; = 'N': do not update Q.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0. If N == 0 arguments ILST and IFST may be any value.

T Input and output parameter.

T is REAL

T is an array, dimension (LDT, N). On entry, the upper quasi-triangular matrix T, in Schur Schur canonical form. On exit, the reordered upper quasi-triangular matrix, again in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix Z which reorders T. If COMPQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1, and if COMPQ = 'V', LDQ >= max(1, N).

IFST Input and output parameter.

IFST is INTEGER

ILST Input and output parameter.

ILST is INTEGER

Specify the reordering of the diagonal blocks of T. The block with row index IFST is moved to row ILST, by a sequence of transpositions between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST <= N; 1 <= ILST <= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1: two adjacent blocks were too close to swap (the problem is very ill-conditioned); T may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

Related Information

For this routine in other precisions, please see *ctrexc*, *dtrexc* and *ztrexc*. It also exists with a native C interface as *LAPACKE_strexc*.

4.13.46 strsen

strsen reorders the real Schur factorization of a real matrix A = Q*T*Q^T , so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine strsen(JOB, COMPQ, SELECT, N, T, LDT, Q, LDQ, WR, WI, M, S, SEP,
                  WORK, LWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void strsen_(const char *job, const char *compq, const armpl_int_t *select,
             const armpl_int_t *n, float *t, const armpl_int_t *ldt, float *q,
             const armpl_int_t *ldq, float *wr, float *wi, armpl_int_t *m,
             float *s, float *sep, float *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, const armpl_int_t *liwork, armpl_int_t *info,
             ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP): = 'N': none; = 'E': for eigenvalues only (S); = 'V': for invariant subspace only (SEP); = 'B': for both eigenvalues and invariant subspace (S and SEP).

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'V': update the matrix Q of Schur vectors; = 'N': do not update Q.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select a complex conjugate pair of eigenvalues w(j) and w(j+1), corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is REAL

T is an array, dimension (LDT, N). On entry, the upper quasi-triangular matrix T, in Schur canonical form. On exit, T is overwritten by the reordered matrix T, again in Schur canonical form, with the selected eigenvalues in the leading diagonal blocks.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; and if COMPQ = 'V', LDQ >= N.

WR Output parameter.

WR is REAL

WR is an array, dimension (N) .

WI Output parameter.

WI is REAL

WI is an array, dimension (N). The real and imaginary parts, respectively, of the reordered eigenvalues of T. The eigenvalues are stored in the same order as on the diagonal of T, with WR(i) = T(i,i) and, if T(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) > 0 and WI(i+1) = -WI(i). Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

M Output parameter.

M is INTEGER

The dimension of the specified invariant subspace. 0 < = M <= N.

S Output parameter.

S is REAL

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of sqrt(N). If M = 0 or N, S = 1. If JOB = 'N' or 'V', S is not referenced.

SEP Output parameter.

SEP is REAL

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If M = 0 or N, SEP = norm(T). If JOB = 'N' or 'E', SEP is not referenced.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOB = 'N', LWORK >= max(1, N); if JOB = 'E', LWORK >= max(1,M*(N-M)); if JOB = 'V' or 'B', LWORK >= max(1,2*M*(N-M)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOB = 'N' or 'E', LIWORK >= 1; if JOB = 'V' or 'B', LIWORK >= max(1,M*(N-M)).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1: reordering of T failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); T may have been partially reordered, and WR and WI contain the eigenvalues in the same order as in T; S and SEP (if requested) are set to zero.

Related Information

For this routine in other precisions, please see *ctrsen*, *dtrsen* and *ztrsen*. It also exists with a native C interface as *LAPACKE_strsen*.

4.13.47 strsna

strsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix $Q*T*Q^T$ with Q orthogonal).

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine strsna(JOB, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, S, SEP,
                  MM, M, WORK, LDWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void strsna_(const char *job, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const float *t, const armpl_int_t *ldt,
             const float *vl, const armpl_int_t *ldvl, const float *vr,
             const armpl_int_t *ldvr, float *s, float *sep,
             const armpl_int_t *mm, armpl_int_t *m, float *work,
             const armpl_int_t *ldwork, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP): = 'E': for eigenvalues only (S); = 'V': for eigenvectors only (SEP); = 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute condition numbers for all eigenpairs; = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues w(j) and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input parameter.

T is REAL

T is an array, dimension (LDT, N). The upper quasi-triangular matrix T, in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input parameter.

VL is REAL

VL is an array, dimension (LDVL, M). If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any Q*T*Q^T with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by SHSEIN or STREVC. If JOB = 'V', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; and if JOB = 'E' or 'B', LDVL >= N.

VR Input parameter.

VR is REAL

VR is an array, dimension (LDVR, M). If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any Q*T*Q^T with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by SHSEIN or STREVC. If JOB = 'V', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; and if JOB = 'E' or 'B', LDVR >= N.

S Output parameter.

S is REAL

S is an array, dimension (MM). If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP Output parameter.

SEP is REAL

SEP is an array, dimension (MM). If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of SEP are set to the same value. If the eigenvalues cannot be reordered to compute SEP(j), SEP(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', SEP is not referenced.

MM Input parameter.

MM is INTEGER

The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M Output parameter.

M is INTEGER

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LDWORK,N+6). If JOB = 'E', WORK is not referenced.

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

IWORK Output parameter.

IWORK is INTEGER array, dimension (2*(N-1))

If JOB = 'E', IWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrsna*, *dtrsna* and *ztrsna*. It also exists with a native C interface as *LAPACKE_strsna*.

4.13.48 strsyl

`strsyl` solves the real Sylvester matrix equation:

```
op(A)*X + X*op(B) = scale*C or
op(A)*X - X*op(B) = scale*C,
```

where op(A) = A or A^T , and A and B are both upper quasi- triangular. A is M-by-M and B is N-by-N; the right hand side C and the solution X are M-by-N; and scale is an output scale factor, set <= 1 to avoid overflow in X.

A and B must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Syntax

Fortran specification:

```
use armpl_library

subroutine strsyl(TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC, SCALE,
                  INFO)
```

C specification:

```
#include "armpl.h"

void strsyl_(const char *trana, const char *tranb, const armpl_int_t *isgn,
             const armpl_int_t *m, const armpl_int_t *n, const float *a,
             const armpl_int_t *lda, const float *b, const armpl_int_t *ldb,
             float *c, const armpl_int_t *ldc, float *scale,
             armpl_int_t *info, ... );
```

Parameters

TRANA Input parameter.

TRANA is CHARACTER*1

Specifies the option op(A): = 'N': op(A) = A (No transpose) = 'T': op(A) = A^T (Transpose) = 'C': op(A) = A^H (Conjugate transpose = Transpose)

TRANB Input parameter.

TRANB is CHARACTER*1

Specifies the option op(B): = 'N': op(B) = B (No transpose) = 'T': op(B) = B^T (Transpose) = 'C': op(B) = B^H (Conjugate transpose = Transpose)

ISGN Input parameter.

ISGN is INTEGER

Specifies the sign in the equation: = +1: solve op(A)*X + X*op(B) = scale*C = -1: solve op(A)*X - X*op(B) = scale* C

M Input parameter.

M is INTEGER

The order of the matrix A, and the number of rows in the matrices X and C. M >= 0.

N Input parameter.

N is INTEGER

The order of the matrix B, and the number of columns in the matrices X and C. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, M). The upper quasi-triangular matrix A, in Schur canonical form.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input parameter.

B is REAL

B is an array, dimension (LDB, N). The upper quasi-triangular matrix B, in Schur canonical form.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, the M-by-N right hand side matrix C. On exit, C is overwritten by the solution matrix X.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M)

SCALE Output parameter.

SCALE is REAL

The scale factor, scale, set <= 1 to avoid overflow in X.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1: A and B have common or very close eigenvalues; perturbed values were used to solve the equation (but the matrices A and B are unchanged).

Related Information

4.13.49 zgebak

zgebak forms the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by ZGEBAL.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgebak(JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
```

C specification:

```
#include "armpl.h"

void zgebak_(const char *job, const char *side, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             const double *scale, const armpl_int_t *m,
             armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to ZGEBAL.

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': V contains right eigenvectors; = 'L': V contains left eigenvectors.

N Input parameter.

N is INTEGER

The number of rows of the matrix V. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

The integers ILO and IHI determined by ZGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

SCALE Input parameter.

SCALE is DOUBLE PRECISION

SCALE is an array, dimension (N). Details of the permutation and scaling factors, as returned by ZGEBAL.

M Input parameter.

M is INTEGER

The number of columns of the matrix V. M >= 0.

V Input and output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, M). On entry, the matrix of right or left eigenvectors to be transformed, as returned by ZHSEIN or ZTREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. LDV >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebak*, *dgebak* and *sgebak*. It also exists with a native C interface as *LAPACKE_zgebak*.

4.13.50 zgebal

zgebal balances a general complex matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgebal(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

C specification:

```
#include "armpl.h"

void zgebal_(const char *job, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ilo, armpl_int_t *ihi,
             double *scale, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the operations to be performed on A: = 'N': none: simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are set to INTEGER such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

SCALE is an array, dimension (N). Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgebal*, *dgebal* and *sgebal*. It also exists with a native C interface as *LAPACKE_zgebal*.

4.13.51 zgees

zgees computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z^H).

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A complex matrix is in Schur form if it is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgees(JOBVS, SORT, SELECT, N, A, LDA, SDIM, W, VS, LDVS, WORK,
                 LWORK, RWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgees_(const char *jobvs, const char *sort, ARMPL_ZGEES_SELECT select,
            const armpl_int_t *n, armpl_doublecomplex_t *a,
            const armpl_int_t *lda, armpl_int_t *sdim,
            armpl_doublecomplex_t *w, armpl_doublecomplex_t *vs,
            const armpl_int_t *ldvs, armpl_doublecomplex_t *work,
            const armpl_int_t *lwork, double *rwork, armpl_int_t *bwork,
            armpl_int_t *info, ... );
```

Parameters

JOBVS Input parameter.

JOBVS is CHARACTER*1

= 'N': Schur vectors are not computed; = 'V': Schur vectors are computed.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered: = 'S': Eigenvalues are ordered (see SELECT).

SELECT Input parameter.

SELECT is a LOGICAL FUNCTION of one COMPLEX*16 argument

SELECT must be declared EXTERNAL in the calling subroutine. If SORT = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. IF SORT = 'N', SELECT is not referenced. The eigenvalue W(j) is selected if SELECT(W(j)) is true.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten by its Schur form T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues for which SELECT is true.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (N). W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

VS Output parameter.

VS is COMPLEX*16

VS is an array, dimension (LDVS, N). If JOBVS = 'V', VS contains the unitary matrix Z of Schur vectors. If JOBVS = 'N', VS is not referenced.

LDVS Input parameter.

LDVS is INTEGER

The leading dimension of the array VS. LDVS >= 1; if JOBVS = 'V', LDVS >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBVS = 'V', VS contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT = .TRUE.. This could also be caused by underflow due to scaling.

Related Information

For this routine in other precisions, please see *cgees*, *dgees* and *sgees*. It also exists with a native C interface as *LAPACKE_zgees*.

4.13.52 zgeesx

zgeesx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z^H).

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A complex matrix is in Schur form if it is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeesx(JOBVS, SORT, SELECT, SENSE, N, A, LDA, SDIM, W, VS, LDVS,
                  RCONDE, RCONDV, WORK, LWORK, RWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeesx_(const char *jobvs, const char *sort, ARMPL_ZGEESX_SELECT select,
             const char *sense, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *sdim, armpl_doublecomplex_t *w,
             armpl_doublecomplex_t *vs, const armpl_int_t *ldvs,
             double *rconde, double *rcondv, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork, armpl_int_t *bwork,
             armpl_int_t *info, ... );
```

Parameters

JOBVS Input parameter.

JOBVS is CHARACTER*1

= 'N': Schur vectors are not computed; = 'V': Schur vectors are computed.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELECT).

SELECT Input parameter.

SELECT is a LOGICAL FUNCTION of one COMPLEX*16 argument

SELECT must be declared EXTERNAL in the calling subroutine. If SORT = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORT = 'N', SELECT is not referenced. An eigenvalue W(j) is selected if SELECT(W(j)) is true.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': None are computed; = 'E': Computed for average of selected eigenvalues only; = 'V': Computed for selected right invariant subspace only; = 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORT must equal 'S'.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A is overwritten by its Schur form T.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues for which SELECT is true.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (N). W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

VS Output parameter.

VS is COMPLEX*16

VS is an array, dimension (LDVS, N). If JOBVS = 'V', VS contains the unitary matrix Z of Schur vectors. If JOBVS = 'N', VS is not referenced.

LDVS Input parameter.

LDVS is INTEGER

The leading dimension of the array VS. LDVS >= 1, and if JOBVS = 'V', LDVS >= N.

RCONDE Output parameter.

RCONDE is DOUBLE PRECISION

If SENSE = 'E' or 'B', RCONDE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV Output parameter.

RCONDV is DOUBLE PRECISION

If SENSE = 'V' or 'B', RCONDV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). Also, if SENSE = 'E' or 'V' or 'B', LWORK >= 2*SDIM*(N-SDIM), where SDIM is the number of selected eigenvalues computed by this routine. Note that 2*SDIM*(N-SDIM) <= N*N/2. Note also that an error is only returned if LWORK < max(1,2*N), but if SENSE = 'E' or 'V' or 'B' this may not be large enough. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates upper bound on the optimal size of the array WORK, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, and i is <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBVS = 'V', VS contains the transformation which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

Related Information

For this routine in other precisions, please see *cgeesx*, *dgeesx* and *sgeesx*. It also exists with a native C interface as *LAPACKE_zgeesx*.

4.13.53 zgeev

zgeev computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector v(j) of A satisfies

```
A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue. The left eigenvector u(j) of A satisfies

```
u(j)**H * A = lambda(j) * u(j)**H
```

where $u(j)^H$ denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeev(JOBVL, JOBVR, N, A, LDA, W, VL, LDVL, VR, LDVR, WORK, LWORK,
                 RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeev_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
            armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *w, armpl_doublecomplex_t *vl,
```

(continues on next page)

(continued from previous page)

```
            const armpl_int_t *ldvl, armpl_doublecomplex_t *vr,
            const armpl_int_t *ldvr, armpl_doublecomplex_t *work,
            const armpl_int_t *lwork, double *rwork, armpl_int_t *info,
            ... );
```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': left eigenvectors of A are not computed; = 'V': left eigenvectors of are computed.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': right eigenvectors of A are not computed; = 'V': right eigenvectors of A are computed.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is COMPLEX*16

W is an array, dimension (N). W contains the computed eigenvalues.

VL Output parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. u(j) = VL(:,j), the j-th column of VL.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. v(j) = VR(:,j), the j-th column of VR.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements and i+1:N of W contain eigenvalues which have converged.

Related Information

For this routine in other precisions, please see *cgeev*, *dgeev* and *sgeev*. It also exists with a native C interface as *LAPACKE_zgeev*.

4.13.54 zgeevx

zgeevx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector v(j) of A satisfies

```
A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue. The left eigenvector u(j) of A satisfies

```
u(j)**H * A = lambda(j) * u(j)**H
```

where $u(j)^H$ denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation D * A * D**(-1), where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgeevx(BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, W, VL, LDVL, VR,
                  LDVR, ILO, IHI, SCALE, ABNRM, RCONDE, RCONDV, WORK, LWORK,
                  RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgeevx_(const char *balanc, const char *jobvl, const char *jobvr,
             const char *sense, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *w, armpl_doublecomplex_t *vl,
             const armpl_int_t *ldvl, armpl_doublecomplex_t *vr,
             const armpl_int_t *ldvr, armpl_int_t *ilo, armpl_int_t *ihi,
             double *scale, double *abnrm, double *rconde, double *rcondv,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

BALANC Input parameter.

BALANC is CHARACTER*1

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute; = 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, ie. replace A by D*A*D**(-1), where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': left eigenvectors of A are not computed; = 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': right eigenvectors of A are not computed; = 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': None are computed; = 'E': Computed for eigenvalues only; = 'V': Computed for right eigenvectors only; = 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the Schur form of the balanced version of the matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is COMPLEX*16

W is an array, dimension (N). W contains the computed eigenvalues.

VL Output parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. u(j) = VL(:,j), the j-th column of VL.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. v(j) = VR(:,j), the j-th column of VR.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; if JOBVR = 'V', LDVR >= N.

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

SCALE is an array, dimension (N). Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM Output parameter.

ABNRM is DOUBLE PRECISION

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONDE Output parameter.

RCONDE is DOUBLE PRECISION

RCONDE is an array, dimension (N). RCONDE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONDV Output parameter.

RCONDV is DOUBLE PRECISION

RCONDV is an array, dimension (N). RCONDV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SENSE = 'N' or 'E', LWORK >= max(1,2*N), and if SENSE = 'V' or 'B', LWORK >= N*N+2*N. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of W contain eigenvalues which have converged.

4.13.55 zgehrd

zgehrd reduces a complex general matrix A to upper Hessenberg form H by an unitary similarity transformation: $Q^H * A * Q = H$.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgehrd(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgehrd_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to ZGEBAL; otherwise they should be set to 1 and N respectively. See Further Details. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= max(1, N). For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgehrd*, *dgehrd* and *sgehrd*. It also exists with a native C interface as *LAPACKE_zgehrd*.

4.13.56 zhsein

zhsein uses inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

```
H * x = w * x,     y**h * H = w * y**h
```

where y**h denotes the conjugate transpose of the vector y.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhsein(SIDE, EIGSRC, INITV, SELECT, N, H, LDH, W, VL, LDVL, VR,
                  LDVR, MM, M, WORK, RWORK, IFAILL, IFAILR, INFO)
```

C specification:

```
#include "armpl.h"

void zhsein_(const char *side, const char *eigsrc, const char *initv,
             const armpl_int_t *select, const armpl_int_t *n,
             const armpl_doublecomplex_t *h, const armpl_int_t *ldh,
             armpl_doublecomplex_t *w, armpl_doublecomplex_t *vl,
             const armpl_int_t *ldvl, armpl_doublecomplex_t *vr,
             const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *ifaill,
             armpl_int_t *ifailr, armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

EIGSRC Input parameter.

EIGSRC is CHARACTER*1

Specifies the source of eigenvalues supplied in W: = 'Q': the eigenvalues were found using ZHSEQR; thus, if H has zero subdiagonal elements, and so is block-triangular, then the j-th eigenvalue can be assumed to be an eigenvalue of the block containing the j-th row/column. This property allows ZHSEIN to perform inverse iteration on just one diagonal block. = 'N': no assumptions are made on the correspondence between eigenvalues and diagonal blocks. In this case, ZHSEIN must always perform inverse iteration using the whole matrix H.

INITV Input parameter.

INITV is CHARACTER*1

= 'N': no initial vectors are supplied; = 'U': user-supplied initial vectors are stored in the arrays VL and/or VR.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). Specifies the eigenvectors to be computed. To select the eigenvector corresponding to the eigenvalue W(j), SELECT(j) must be set to .TRUE..

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

H Input parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). The upper Hessenberg matrix H. If a NaN is detected in H, the routine will return with INFO=-6.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

W Input and output parameter.

W is COMPLEX*16

W is an array, dimension (N). On entry, the eigenvalues of H. On exit, the real parts of W may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

VL Input and output parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, MM). On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= max(1, N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR Input and output parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, MM). On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= max(1, N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR required to store the eigenvectors (= the number of .TRUE. elements in SELECT).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

IFAILL Output parameter.

IFAILL is INTEGER array, dimension (MM)

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'R', IFAILL is not referenced.

IFAILR Output parameter.

IFAILR is INTEGER array, dimension (MM)

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'L', IFAILR is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

Related Information

For this routine in other precisions, please see *chsein*, *dhsein* and *shsein*. It also exists with a native C interface as *LAPACKE_zhsein*.

4.13.57 zhseqr

```
ZHSEQR computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**H, where T is an upper triangular matrix (the
   Schur form), and Z is the unitary matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input unitary
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the unitary matrix Q:  A = Q*H*Q**H = (QZ)*T*(QZ)**H.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zhseqr(JOB, COMPZ, N, ILO, IHI, H, LDH, W, Z, LDZ, WORK, LWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zhseqr_(const char *job, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             armpl_doublecomplex_t *h, const armpl_int_t *ldh,
             armpl_doublecomplex_t *w, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

= 'E': compute eigenvalues only; = 'S': compute eigenvalues and the Schur form T.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': no Schur vectors are computed; = 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = 'V': Z must contain an unitary matrix Q on entry, and the product Q* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to ZGEBAL, and then passed to ZGEHRD when the matrix output by

ZGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and JOB = 'S', H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If INFO = 0 and JOB = 'E', the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

Unlike earlier versions of ZHSEQR, this subroutine may explicitly H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

W Output parameter.

W is COMPLEX*16

W is an array, dimension (N). The computed eigenvalues. If JOB = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with W(i) = H(i,i).

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If COMPZ = 'N', Z is not referenced. If COMPZ = 'I', on entry Z need not be set and on exit, if INFO = 0, Z contains the unitary matrix Z of the Schur vectors of H. If COMPZ = 'V', on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the submatrix Z(ILO:IHI,ILO:IHI). On exit, if INFO = 0, Z contains Q*Z. Normally Q is the unitary matrix generated by ZUNGHR after the call to ZGEHRD which formed the Hessenberg matrix H. (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if COMPZ = 'I' or COMPZ = 'V', then LDZ.GE.MAX(1, N). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient and delivers very good and sometimes optimal performance. However, LWORK as large as 11*N may be required for optimal performance. A workspace query is recommended to determine the optimal workspace size.

If LWORK = -1, then ZHSEQR does a workspace query. In this case, ZHSEQR checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .LT. 0: if INFO = -i, the i-th argument had an illegal value .GT. 0: if INFO = i, ZHSEQR failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and JOB = 'E', then on exit, the remaining unconverged eigenvalues are the eigen- values of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and JOB = 'S', then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is a unitary matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and COMPZ = 'V', then on exit

(final value of Z) = (initial value of Z)*U

where U is the unitary matrix in (*) (regard- less of the value of JOB.)

If INFO .GT. 0 and COMPZ = 'I', then on exit (final value of Z) = U where U is the unitary matrix in (*) (regard- less of the value of JOB.)

If INFO .GT. 0 and COMPZ = 'N', then Z is not accessed.

Related Information

For this routine in other precisions, please see *chseqr*, *dhseqr* and *shseqr*. It also exists with a native C interface as *LAPACKE_zhseqr*.

4.13.58 ztrevc

ztrevc computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T. Matrices of this type are produced by the Schur factorization of a complex general matrix: A = Q*T*Q^H , as computed by ZHSEQR.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
T*x = w*x,     (y**H)*T = w*(y**H)
```

where y^H denotes the conjugate transpose of the vector y. The eigenvalues are not input to this routine, but are read directly from the diagonal of T.

This routine returns the matrices X and/or Y of right and left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input matrix. If Q is the unitary factor that reduces a matrix A to Schur form T, then Q*X and Q*Y are the matrices of right and left eigenvectors of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrevc(SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, MM, M,
                  WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztrevc_(const char *side, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, armpl_doublecomplex_t *t,
```

(continues on next page)

(continued from previous page)

```
                const armpl_int_t *ldt, armpl_doublecomplex_t *vl,
                const armpl_int_t *ldvl, armpl_doublecomplex_t *vr,
                const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
                armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
                ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed using the matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, as indicated by the logical array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. The eigenvector corresponding to the j-th eigenvalue is computed if SELECT(j) = .TRUE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). The upper triangular matrix T. T is modified, but restored on exit.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input and output parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by ZHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1, and if SIDE = 'L' or 'B', LDVL >= N.

VR Input and output parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by ZHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B'; LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrevc*, *dtrevc* and *strevc*. It also exists with a native C interface as *LAPACKE_ztrevc*.

4.13.59 ztrexc

ztrexc reorders the Schur factorization of a complex matrix A = Q*T*Q^H , so that the diagonal element of T with row index IFST is moved to row ILST.

The Schur form T is reordered by a unitary similarity transformation Z^H *T*Z, and optionally the matrix Q of Schur vectors is updated by postmultplying it with Z.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrexc(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)
```

C specification:

```
#include "armpl.h"

void ztrexc_(const char *compq, const armpl_int_t *n,
             armpl_doublecomplex_t *t, const armpl_int_t *ldt,
             armpl_doublecomplex_t *q, const armpl_int_t *ldq,
             const armpl_int_t *ifst, const armpl_int_t *ilst,
             armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'V': update the matrix Q of Schur vectors; = 'N': do not update Q.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0. If N == 0 arguments ILST and IFST may be any value.

T Input and output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). On entry, the upper triangular matrix T. On exit, the reordered upper triangular matrix.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix Z which reorders T. If COMPQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1, and if COMPQ = 'V', LDQ >= max(1, N).

IFST Input parameter.

IFST is INTEGER

ILST Input parameter.

ILST is INTEGER

Specify the reordering of the diagonal elements of T: The element with row index IFST is moved to row ILST by a sequence of transpositions between adjacent elements. 1 <= IFST <= N; 1 <= ILST <= N.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrexc*, *dtrexc* and *strexc*. It also exists with a native C interface as *LAPACKE_ztrexc*.

4.13.60 ztrsen

`ztrsen` reorders the Schur factorization of a complex matrix A = Q*T*Q^H , so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrsen(JOB, COMPQ, SELECT, N, T, LDT, Q, LDQ, W, M, S, SEP, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztrsen_(const char *job, const char *compq, const armpl_int_t *select,
             const armpl_int_t *n, armpl_doublecomplex_t *t,
             const armpl_int_t *ldt, armpl_doublecomplex_t *q,
             const armpl_int_t *ldq, armpl_doublecomplex_t *w, armpl_int_t *m,
             double *s, double *sep, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP): = 'N': none; = 'E': for eigenvalues only (S); = 'V': for invariant subspace only (SEP); = 'B': for both eigenvalues and invariant subspace (S and SEP).

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'V': update the matrix Q of Schur vectors; = 'N': do not update Q.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). SELECT specifies the eigenvalues in the selected cluster. To select the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). On entry, the upper triangular matrix T. On exit, T is overwritten by the reordered matrix T, with the selected eigenvalues as the leading diagonal elements.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; and if COMPQ = 'V', LDQ >= N.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (N). The reordered eigenvalues of T, in the same order as they appear on the diagonal of T.

M Output parameter.

M is INTEGER

The dimension of the specified invariant subspace. 0 <= M <= N.

S Output parameter.

S is DOUBLE PRECISION

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of sqrt(N). If M = 0 or N, S = 1. If JOB = 'N' or 'V', S is not referenced.

SEP Output parameter.

SEP is DOUBLE PRECISION

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If M = 0 or N, SEP = norm(T). If JOB = 'N' or 'E', SEP is not referenced.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOB = 'N', LWORK >= 1; if JOB = 'E', LWORK = max(1,M*(N-M)); if JOB = 'V' or 'B', LWORK >= max(1,2*M*(N-M)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrsen*, *dtrsen* and *strsen*. It also exists with a native C interface as *LAPACKE_ztrsen*.

4.13.61 ztrsna

ztrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix Q*T*Q^H with Q unitary).

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrsna(JOB, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, S, SEP,
                  MM, M, WORK, LDWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztrsna_(const char *job, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const armpl_doublecomplex_t *t,
             const armpl_int_t *ldt, const armpl_doublecomplex_t *vl,
             const armpl_int_t *ldvl, const armpl_doublecomplex_t *vr,
             const armpl_int_t *ldvr, double *s, double *sep,
             const armpl_int_t *mm, armpl_int_t *m,
             armpl_doublecomplex_t *work, const armpl_int_t *ldwork,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP): = 'E': for eigenvalues only (S); = 'V': for eigenvectors only (SEP); = 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute condition numbers for all eigenpairs; = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the j-th eigenpair, SELECT(j) must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). The upper triangular matrix T.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, M). If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any Q*T*Q^H with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by ZHSEIN or ZTREVC. If JOB = 'V', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; and if JOB = 'E' or 'B', LDVL >= N.

VR Input parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, M). If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any Q*T*Q^H with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by ZHSEIN or ZTREVC. If JOB = 'V', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; and if JOB = 'E' or 'B', LDVR >= N.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (MM). If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP Output parameter.

SEP is DOUBLE PRECISION

SEP is an array, dimension (MM). If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If JOB = 'E', SEP is not referenced.

MM Input parameter.

MM is INTEGER

The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M Output parameter.

M is INTEGER

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LDWORK,N+6). If JOB = 'E', WORK is not referenced.

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N). If JOB = 'E', RWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrsna*, *dtrsna* and *strsna*. It also exists with a native C interface as *LAPACKE_ztrsna*.

4.13.62 ztrsyl

ztrsyl solves the complex Sylvester matrix equation:

```
op(A)*X + X*op(B) = scale*C or
op(A)*X - X*op(B) = scale*C,
```

where op(A) = A or A^H , and A and B are both upper triangular. A is M-by-M and B is N-by-N; the right hand side C and the solution X are M-by-N; and scale is an output scale factor, set <= 1 to avoid overflow in X.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrsyl(TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC, SCALE,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ztrsyl_(const char *trana, const char *tranb, const armpl_int_t *isgn,
             const armpl_int_t *m, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *c, const armpl_int_t *ldc, double *scale,
             armpl_int_t *info, ... );
```

Parameters

TRANA Input parameter.

TRANA is CHARACTER*1

Specifies the option op(A): = 'N': op(A) = A (No transpose) = 'C': op(A) = A^H (Conjugate transpose)

TRANB Input parameter.

TRANB is CHARACTER*1

Specifies the option op(B): = 'N': op(B) = B (No transpose) = 'C': op(B) = B^H (Conjugate transpose)

ISGN Input parameter.

ISGN is INTEGER

Specifies the sign in the equation: = +1: solve op(A)*X + X*op(B) = scale*C = -1: solve op(A)*X - X*op(B) = scale* C

M Input parameter.

M is INTEGER

The order of the matrix A, and the number of rows in the matrices X and C. M >= 0.

N Input parameter.

N is INTEGER

The order of the matrix B, and the number of columns in the matrices X and C. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, M). The upper triangular matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). The upper triangular matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N right hand side matrix C. On exit, C is overwritten by the solution matrix X.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M)

SCALE Output parameter.

SCALE is DOUBLE PRECISION

The scale factor, scale, set <= 1 to avoid overflow in X.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1: A and B have common or very close eigenvalues; perturbed values were used to solve the equation (but the matrices A and B are unchanged).

Related Information

For this routine in other precisions, please see *ctrsyl*, *dtrsyl* and *strsyl*. It also exists with a native C interface as *LAPACKE_ztrsyl*.

4.13.63 zunghr

zunghr generates a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by ZGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine zunghr(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunghr_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix Q. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI must have the same values as in the previous call of ZGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the vectors which define the elementary reflectors, as returned by ZGEHRD. On exit, the N-by-N unitary matrix Q.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-1). TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEHRD.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= IHI-ILO. For optimum performance LWORK >= (IHI-ILO)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunghr*. It also exists with a native C interface as *LAPACKE_zunghr*.

4.13.64 zunmhr

zunmhr overwrites the general complex M-by-N matrix C with

```
SIDE = 'L'     SIDE = 'R'
```

TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by ZGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Syntax

Fortran specification:

```
use armpl_library

subroutine zunmhr(SIDE, TRANS, M, N, ILO, IHI, A, LDA, TAU, C, LDC, WORK,
                  LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zunmhr_(const char *side, const char *trans, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_doublecomplex_t *tau,
             armpl_doublecomplex_t *c, const armpl_int_t *ldc,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply Q (No transpose) = 'C': apply Q^H (Conjugate transpose)

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI must have the same values as in the previous call of ZGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). If SIDE = 'L', then 1 <= ILO <= IHI <= M, if M > 0, and ILO = 1 and IHI = 0, if M = 0; if SIDE = 'R', then 1 <= ILO <= IHI <= N, if N > 0, and ILO = 1 and IHI = 0, if N = 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension. (LDA, M) if SIDE = 'L' (LDA, N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by ZGEHRD.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M) if SIDE = 'L'; LDA >= max(1, N) if SIDE = 'R'.

TAU Input parameter.

TAU is COMPLEX*16

TAU is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by ZGEHRD.

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, N); if SIDE = 'R', LWORK >= max(1, M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cunmhr*. It also exists with a native C interface as *LAPACKE_zunmhr*.

4.14 LAPACK generalized non symmetric eigenvalues routines

4.14.1 cggbak

cggbak forms the right or left eigenvectors of a complex generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL.

Syntax

Fortran specification:

```
use armpl_library

subroutine cggbak(JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V, LDV, INFO)
```

C specification:

```
#include "armpl.h"

void cggbak_(const char *job, const char *side, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             const float *lscale, const float *rscale, const armpl_int_t *m,
             armpl_singlecomplex_t *v, const armpl_int_t *ldv,
             armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the type of backward transformation required: = 'N': do nothing, return immediately; = 'P': do backward transformation for permutation only; = 'S': do backward transformation for scaling only; = 'B': do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to CGGBAL.

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': V contains right eigenvectors; = 'L': V contains left eigenvectors.

N Input parameter.

N is INTEGER

The number of rows of the matrix V. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

The integers ILO and IHI determined by CGGBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

LSCALE Input parameter.

LSCALE is REAL

LSCALE is an array, dimension (N). Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by CGGBAL.

RSCALE Input parameter.

RSCALE is REAL

RSCALE is an array, dimension (N). Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by CGGBAL.

M Input parameter.

M is INTEGER

The number of columns of the matrix V. M >= 0.

V Input and output parameter.

V is COMPLEX

V is an array, dimension (LDV, M). On entry, the matrix of right or left eigenvectors to be transformed, as returned by CTGEVC. On exit, V is overwritten by the transformed eigenvectors.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the matrix V. LDV >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dggbak*, *sggbak* and *zggbak*. It also exists with a native C interface as *LAPACKE_cggbak*.

4.14.2 cggbal

cggbal balances a pair of general complex matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem A*x = lambda*B*x.

Syntax

Fortran specification:

```
use armpl_library

subroutine cggbal(JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cggbal_(const char *job, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *ilo, armpl_int_t *ihi,
             float *lscale, float *rscale, float *work, armpl_int_t *info,
             ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the operations to be performed on A and B: = 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i=1,...,N; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are set to integers such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,. . . ,ILO-1 or i = IHI+1,. . . ,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE Output parameter.

LSCALE is REAL

LSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then LSCALE(j) = P(j) for J = 1,. . . ,ILO-1 = D(j) for J = ILO,. . . ,IHI = P(j) for J = IHI+1,. . . ,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE Output parameter.

RSCALE is REAL

RSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then RSCALE(j) = P(j) for J = 1,. . . ,ILO-1 = D(j) for J = ILO,. . . ,IHI = P(j) for J = IHI+1,. . . ,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (lwork). lwork must be at least max(1,6*N) when JOB = 'S' or 'B', and at least 1 when JOB = 'N' or 'P'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dggbal*, *sggbal* and *zggbal*. It also exists with a native C interface as *LAPACKE_cggbal*.

4.14.3 cgges

`cgges` computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )
```

where $(VSR)^H$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver CGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgges(JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB, SDIM, ALPHA,
                 BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK, RWORK, BWORK,
                 INFO)
```

C specification:

```
#include "armpl.h"

void cgges_(const char *jobvsl, const char *jobvsr, const char *sort,
            ARMPL_CGGES_SELCTG selctg, const armpl_int_t *n,
            armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *b, const armpl_int_t *ldb,
            armpl_int_t *sdim, armpl_singlecomplex_t *alpha,
            armpl_singlecomplex_t *beta, armpl_singlecomplex_t *vsl,
            const armpl_int_t *ldvsl, armpl_singlecomplex_t *vsr,
            const armpl_int_t *ldvsr, armpl_singlecomplex_t *work,
            const armpl_int_t *lwork, float *rwork, armpl_int_t *bwork,
            armpl_int_t *info, ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG).

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of two COMPLEX arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue ALPHA(j)/BETA(j) is selected if SELCTG(ALPHA(j),BETA(j)) is true.

Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+2 (See INFO below).

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

ALPHA Output parameter.

ALPHA is COMPLEX

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A, B) output by CGGES. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is COMPLEX

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >= 1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is COMPLEX

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (8*N) .

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. =1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ =N+2: after reordering, roundoff changed values

of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in CTGSEN.

Related Information

For this routine in other precisions, please see *dgges*, *sgges* and *zgges*. It also exists with a native C interface as *LAPACKE_cgges*.

4.14.4 cgges3

`cgges3` computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )
```

where $(VSR)^H$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver CGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgges3(JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB, SDIM,
                  ALPHA, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK, RWORK,
                  BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgges3_(const char *jobvsl, const char *jobvsr, const char *sort,
             ARMPL_CGGES3_SELCTG selctg, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *sdim, armpl_singlecomplex_t *alpha,
             armpl_singlecomplex_t *beta, armpl_singlecomplex_t *vsl,
             const armpl_int_t *ldvsl, armpl_singlecomplex_t *vsr,
             const armpl_int_t *ldvsr, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork, armpl_int_t *bwork,
             armpl_int_t *info, ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG).

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of two COMPLEX arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue ALPHA(j)/BETA(j) is selected if SELCTG(ALPHA(j),BETA(j)) is true.

Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+2 (See INFO below).

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

ALPHA Output parameter.

ALPHA is COMPLEX

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A, B) output by CGGES3. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is COMPLEX

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >= 1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is COMPLEX

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (8*N) .

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. =1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in CTGSEN.

Related Information

For this routine in other precisions, please see *dgges3*, *sgges3* and *zgges3*. It also exists with a native C interface as *LAPACKE_cgges3*.

4.14.5 cggesx

cggesx computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL) S (VSR)**H, (VSL) T (VSR)**H )
```

where $(VSR)^H$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if T is upper triangular with non-negative diagonal and S is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine cggesx(JOBVSL, JOBVSR, SORT, SELCTG, SENSE, N, A, LDA, B, LDB,
                  SDIM, ALPHA, BETA, VSL, LDVSL, VSR, LDVSR, RCONDE, RCONDV,
                  WORK, LWORK, RWORK, IWORK, LIWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cggesx_(const char *jobvsl, const char *jobvsr, const char *sort,

                const armpl_int_t *liwork, armpl_int_t *bwork, armpl_int_t *info,
                ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG).

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of two COMPLEX arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3 see INFO below).

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N' : None are computed; = 'E' : Computed for average of selected eigenvalues only; = 'V' : Computed for selected deflating subspaces only; = 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

ALPHA Output parameter.

ALPHA is COMPLEX

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHA(j) and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T). BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is COMPLEX

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is COMPLEX

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

RCONDE Output parameter.

RCONDE is REAL

RCONDE is an array, dimension (2). If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV Output parameter.

RCONDV is REAL

RCONDV is an array, dimension (2). If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition number for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N = 0, LWORK >= 1, else if SENSE = 'E', 'V', or 'B', LWORK >= MAX(1,2*N,2*SDIM*(N-SDIM)), else LWORK >= MAX(1,2*N). Note that 2*SDIM*(N-SDIM) <= N*N/2. Note also that an error is only returned if LWORK < MAX(1,2*N), but if SENSE = 'E' or 'V' or 'B' this may not be large enough.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the WORK array and the minimum size of the IWORK array, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (8* N). Real workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array WORK. If SENSE = 'N' or N = 0, LIWORK >= 1, otherwise LIWORK >= N+2.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the WORK array and the minimum size of the IWORK array, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in CTGSEN.

Related Information

For this routine in other precisions, please see *dggesx*, *sggesx* and *zggesx*. It also exists with a native C interface as *LAPACKE_cggesx*.

4.14.6 cggev

`cggev` computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right generalized eigenvector v(j) corresponding to the generalized eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j).
```

The left generalized eigenvector u(j) corresponding to the generalized eigenvalues lambda(j) of (A,B) satisfies

```
u(j)**H * A = lambda(j) * u(j)**H * B
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine cggev(JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHA, BETA, VL, LDVL, VR,
                 LDVR, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cggev_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
            armpl_singlecomplex_t *a, const armpl_int_t *lda,
            armpl_singlecomplex_t *b, const armpl_int_t *ldb,
            armpl_singlecomplex_t *alpha, armpl_singlecomplex_t *beta,
            armpl_singlecomplex_t *vl, const armpl_int_t *ldvl,
            armpl_singlecomplex_t *vr, const armpl_int_t *ldvr,
            armpl_singlecomplex_t *work, const armpl_int_t *lwork,
            float *rwork, armpl_int_t *info, ... );
```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,. . . , N, will be the generalized eigenvalues.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left generalized eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right generalized eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (8*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. =1,. . . ,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,. . . ,N. > N: =N+1: other then QZ iteration failed in SHGEQZ, =N+2: error return from STGEVC.

Related Information

For this routine in other precisions, please see *dggev*, *sggev* and *zggev*. It also exists with a native C interface as *LAPACKE_cggev*.

4.14.7 cggev3

cggev3 computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right generalized eigenvector v(j) corresponding to the generalized eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j).
```

The left generalized eigenvector u(j) corresponding to the generalized eigenvalues lambda(j) of (A,B) satisfies

```
u(j)**H * A = lambda(j) * u(j)**H * B
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine cggev3(JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHA, BETA, VL, LDVL, VR,
                  LDVR, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cggev3_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *alpha, armpl_singlecomplex_t *beta,
             armpl_singlecomplex_t *vl, const armpl_int_t *ldvl,
             armpl_singlecomplex_t *vr, const armpl_int_t *ldvr,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left generalized eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right generalized eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (8*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. =1,. . . ,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,. . . ,N. > N: =N+1: other then QZ iteration failed in SHGEQZ, =N+2: error return from STGEVC.

4.14.8 cggevx

cggevx computes for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally, it also computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j) .
```

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
u(j)**H * A  = lambda(j) * u(j)**H * B.
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine cggevx(BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, B, LDB, ALPHA, BETA,
                  VL, LDVL, VR, LDVR, ILO, IHI, LSCALE, RSCALE, ABNRM, BBNRM,
                  RCONDE, RCONDV, WORK, LWORK, RWORK, IWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cggevx_(const char *balanc, const char *jobvl, const char *jobvr,
             const char *sense, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *alpha, armpl_singlecomplex_t *beta,
             armpl_singlecomplex_t *vl, const armpl_int_t *ldvl,
             armpl_singlecomplex_t *vr, const armpl_int_t *ldvr,
             armpl_int_t *ilo, armpl_int_t *ihi, float *lscale, float *rscale,
             float *abnrm, float *bbnrm, float *rconde, float *rcondv,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             float *rwork, armpl_int_t *iwork, armpl_int_t *bwork,
             armpl_int_t *info, ... );
```

Parameters

BALANC Input parameter.

BALANC is CHARACTER*1

Specifies the balance option to be performed: = 'N': do not diagonally scale or permute; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': none are computed; = 'E': computed for eigenvalues only; = 'V': computed for eigenvectors only; = 'B': computed for eigenvalues and eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the complex Schur form of the "balanced" versions of the input A and B.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the complex Schur form of the "balanced" versions of the input A and B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues.

Note: the quotient ALPHA(j)/BETA(j)) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left generalized eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right generalized eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are integer values such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE Output parameter.

LSCALE is REAL

LSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1 = DL(j) for j = ILO,...,IHI = PL(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE Output parameter.

RSCALE is REAL

RSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1 = DR(j) for j = ILO,...,IHI = PR(j) for j = IHI+1,...,N The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM Output parameter.

ABNRM is REAL

The one-norm of the balanced matrix A.

BBNRM Output parameter.

BBNRM is REAL

The one-norm of the balanced matrix B.

RCONDE Output parameter.

RCONDE is REAL

RCONDE is an array, dimension (N). If SENSE = 'E' or 'B', the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. If SENSE = 'N' or 'V', RCONDE is not referenced.

RCONDV Output parameter.

RCONDV is REAL

RCONDV is an array, dimension (N). If SENSE = 'V' or 'B', the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'N' or 'E', RCONDV is not referenced.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). If SENSE = 'E', LWORK >= max(1,4*N). If SENSE = 'V' or 'B', LWORK >= max(1,2*N*N+2*N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (lrwork). lrwork must be at least max(1,6*N) if BALANC = 'S' or 'B', and at least max(1,2*N) otherwise. Real workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N+2)

If SENSE = 'E', IWORK is not referenced.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). If SENSE = 'N', BWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ. =N+2: error return from CTGEVC.

4.14.9 cgghd3

cgghd3 reduces a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is

```
A*x = lambda*B*x,
```

and B is typically made upper triangular by computing its QR factorization and moving the unitary matrix Q to the left side of the equation.

This subroutine simultaneously reduces A to a Hessenberg matrix H:

```
Q**H*A*Z = H
```

and transforms B to another upper triangular matrix T:

```
Q**H*B*Z = T
```

in order to reduce the problem to its standard form

```
H*y = lambda*T*y
```

where y = Z^H *x.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

```
 Q1 * A * Z1**H = (Q1*Q) * H * (Z1*Z)**H

Q1 * B * Z1**H = (Q1*Q) * T * (Z1*Z)**H
```

If Q1 is the unitary matrix from the QR factorization of B in the original equation A*x = lambda*B*x, then `cgghd3` reduces the original problem to generalized Hessenberg form.

This is a blocked variant of CGGHRD, using matrix-matrix multiplications for parts of the computation to enhance performance.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgghd3(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgghd3_(const char *compq, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *q, const armpl_int_t *ldq,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

`COMPQ` is `CHARACTER*1`

= 'N': do not compute Q; = 'I': `Q` is initialized to the unit matrix, and the unitary matrix `Q` is returned; = 'V': `Q` must contain a unitary matrix Q1 on entry, and the product Q1* `Q` is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': do not compute Z; = 'I': Z is initialized to the unit matrix, and the unitary matrix Z is returned; = 'V': Z must contain a unitary matrix Z1 on entry, and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q^H B Z. The elements below the diagonal are set to zero.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the unitary matrix Q1, typically from the QR factorization of B. On exit, if COMPQ='I', the unitary matrix Q, and if COMPQ = 'V', the product Q1*Q. Not referenced if COMPQ='N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the unitary matrix Z1. On exit, if COMPZ='I', the unitary matrix Z, and if COMPZ = 'V', the product Z1*Z. Not referenced if COMPZ='N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1. For optimum performance LWORK >= 6*N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgghd3*, *sgghd3* and *zgghd3*. It also exists with a native C interface as *LAPACKE_cgghd3*.

4.14.10 cgghrd

cgghrd reduces a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is

```
A*x = lambda*B*x,
```

and B is typically made upper triangular by computing its QR factorization and moving the unitary matrix Q to the left side of the equation.

This subroutine simultaneously reduces A to a Hessenberg matrix H:

```
Q**H*A*Z = H
```

and transforms B to another upper triangular matrix T:

```
Q**H*B*Z = T
```

in order to reduce the problem to its standard form

```
H*y = lambda*T*y
```

where y = Z^H *x.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

```
 Q1 * A * Z1**H = (Q1*Q) * H * (Z1*Z)**H
Q1 * B * Z1**H = (Q1*Q) * T * (Z1*Z)**H
```

If Q1 is the unitary matrix from the QR factorization of B in the original equation A*x = lambda*B*x, then `cgghrd` reduces the original problem to generalized Hessenberg form.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgghrd(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cgghrd_(const char *compq, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *q, const armpl_int_t *ldq,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'N': do not compute Q; = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': do not compute Z; = 'I': Z is initialized to the unit matrix, and the unitary matrix Z is returned; = 'V': Z must contain a unitary matrix Z1 on entry, and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q^H B Z. The elements below the diagonal are set to zero.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the unitary matrix Q1, typically from the QR factorization of B. On exit, if COMPQ='I', the unitary matrix Q, and if COMPQ = 'V', the product Q1*Q. Not referenced if COMPQ='N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the unitary matrix Z1. On exit, if COMPZ='I', the unitary matrix Z, and if COMPZ = 'V', the product Z1*Z. Not referenced if COMPZ='N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgghrd*, *sgghrd* and *zgghrd*. It also exists with a native C interface as *LAPACKE_cgghrd*.

4.14.11 chgeqz

chgeqz computes the eigenvalues of a complex matrix pair (H,T), where H is an upper Hessenberg matrix and T is upper triangular, using the single-shift QZ method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a complex matrix pair (A,B):

```
A = Q1*H*Z1**H,  B = Q1*T*Z1**H,
```

as computed by CGGHRD.

If JOB='S', then the Hessenberg-triangular pair (H,T) is also reduced to generalized Schur form,

```
H = Q*S*Z**H,  T = Q*P*Z**H,
```

where Q and Z are unitary matrices and S and P are upper triangular.

Optionally, the unitary matrix Q from the generalized Schur factorization may be postmultiplied into an input matrix Q1, and the unitary matrix Z may be postmultiplied into an input matrix Z1. If Q1 and Z1 are the unitary matrices from CGGHRD that reduced the matrix pair (A,B) to generalized Hessenberg form, then the output matrices Q1*Q and Z1*Z are the unitary factors from the generalized Schur factorization of (A,B):

```
A = (Q1*Q)*S*(Z1*Z)**H,  B = (Q1*Q)*P*(Z1*Z)**H.
```

To avoid overflow, eigenvalues of the matrix pair (H,T) (equivalently, of (A,B)) are computed as a pair of complex values (alpha,beta). If beta is nonzero, lambda = alpha / beta is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

```
A*x = lambda*B*x
```

and if alpha is nonzero, mu = beta / alpha is an eigenvalue of the alternate form of the GNEP

```
mu*A*y = B*y.
```

The values of alpha and beta for the i-th eigenvalue can be read directly from the generalized Schur form: alpha = S(i,i), beta = P(i,i).

Ref: C.B. Moler & G.W. Stewart, “An Algorithm for Generalized Matrix Eigenvalue Problems”, SIAM J. Numer. Anal., 10(1973), pp. 241–256.

Syntax

Fortran specification:

```
use armpl_library

subroutine chgeqz(JOB, COMPQ, COMPZ, N, ILO, IHI, H, LDH, T, LDT, ALPHA, BETA,
                  Q, LDQ, Z, LDZ, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chgeqz_(const char *job, const char *compq, const char *compz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_singlecomplex_t *h,
             const armpl_int_t *ldh, armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, armpl_singlecomplex_t *alpha,
             armpl_singlecomplex_t *beta, armpl_singlecomplex_t *q,
             const armpl_int_t *ldq, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

= ‘E’: Compute eigenvalues only; = ‘S’: Computer eigenvalues and the Schur form.

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'N': Left Schur vectors (Q) are not computed; = 'I': Q is initialized to the unit matrix and the matrix Q of left Schur vectors of (H, T) is returned; = 'V': Q must contain a unitary matrix Q1 on entry and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Right Schur vectors (Z) are not computed; = 'I': Q is initialized to the unit matrix and the matrix Z of right Schur vectors of (H, T) is returned; = 'V': Z must contain a unitary matrix Z1 on entry and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices H, T, Q, and Z. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of H which are in Hessenberg form. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. If N > 0, 1 <= ILO <= IHI <= N; if N = 0, ILO=1 and IHI=0.

H Input and output parameter.

H is COMPLEX

H is an array, dimension (LDH, N). On entry, the N-by-N upper Hessenberg matrix H. On exit, if JOB = 'S', H contains the upper triangular matrix S from the generalized Schur factorization. If JOB = 'E', the diagonal of H matches that of S, but the rest of H is unspecified.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

T Input and output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). On entry, the N-by-N upper triangular matrix T. On exit, if JOB = 'S', T contains the upper triangular matrix P from the generalized Schur factorization. If JOB = 'E', the diagonal of T matches that of P, but the rest of T is unspecified.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX

ALPHA is an array, dimension (N). The complex scalars alpha that define the eigenvalues of GNEP. ALPHA(i) = S(i,i) in the generalized Schur factorization.

BETA Output parameter.

BETA is COMPLEX

BETA is an array, dimension (N). The real non-negative scalars beta that define the eigenvalues of GNEP. BETA(i) = P(i,i) in the generalized Schur factorization.

Together, the quantities alpha = ALPHA(j) and beta = BETA(j) represent the j-th eigenvalue of the matrix pair (A,B), in one of the forms lambda = alpha/beta or mu = beta/alpha. Since either lambda or mu may overflow, they should not, in general, be computed.

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the unitary matrix Q1 used in the reduction of (A,B) to generalized Hessenberg form. On exit, if COMPQ = 'I', the unitary matrix of left Schur vectors of (H, T), and if COMPQ = 'V', the unitary matrix of left Schur vectors of (A,B). Not referenced if COMPQ = 'N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If COMPQ='V' or 'I', then LDQ >= N.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the unitary matrix Z1 used in the reduction of (A,B) to generalized Hessenberg form. On exit, if COMPZ = 'I', the unitary matrix of right Schur vectors of (H, T), and if COMPZ = 'V', the unitary matrix of right Schur vectors of (A,B). Not referenced if COMPZ = 'N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If COMPZ='V' or 'I', then LDZ >= N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1,...,N: the QZ iteration did not converge. (H, T) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (H, T) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO-N+1,...,N should be correct.

Related Information

For this routine in other precisions, please see *dhgeqz*, *shgeqz* and *zhgeqz*. It also exists with a native C interface as *LAPACKE_chgeqz*.

4.14.12 ctgevc

`ctgevc` computes some or all of the right and/or left eigenvectors of a pair of complex matrices (S,P), where S and P are upper triangular. Matrix pairs of this type are produced by the generalized Schur factorization of a complex matrix pair (A,B):

```
A = Q*S*Z**H,  B = Q*P*Z**H
```

as computed by CGGHRD + CHGEQZ.

The right eigenvector x and the left eigenvector y of (S,P) corresponding to an eigenvalue w are defined by:

```
S*x = w*P*x,  (y**H)*S = w*(y**H)*P,
```

where y^H denotes the conjugate tranpose of y. The eigenvalues are not input to this routine, but are computed directly from the diagonal elements of S and P.

This routine returns the matrices X and/or Y of right and left eigenvectors of (S,P), or the products Z*X and/or Q*Y, where Z and Q are input matrices. If Q and Z are the unitary factors from the generalized Schur factorization of a matrix pair (A,B), then Z*X and Q*Y are the matrices of right and left eigenvectors of (A,B).

Syntax

Fortran specification:

```
use armpl_library

subroutine ctgevc(SIDE, HOWMNY, SELECT, N, S, LDS, P, LDP, VL, LDVL, VR, LDVR,
                  MM, M, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctgevc_(const char *side, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const armpl_singlecomplex_t *s,
             const armpl_int_t *lds, const armpl_singlecomplex_t *p,
             const armpl_int_t *ldp, armpl_singlecomplex_t *vl,
             const armpl_int_t *ldvl, armpl_singlecomplex_t *vr,
             const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

SIDE Input parameter.

`SIDE` is `CHARACTER*1`

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

`HOWMNY` is `CHARACTER*1`

= ‘A’: compute all right and/or left eigenvectors; = ‘B’: compute all right and/or left eigenvectors, backtransformed by the matrices in VR and/or VL; = ‘S’: compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY=’S’, SELECT specifies the eigenvectors to be computed. The eigenvector corresponding to the j-th eigenvalue is computed if SELECT(j) = .TRUE.. Not referenced if HOWMNY = ‘A’ or ‘B’.

N Input parameter.

N is INTEGER

The order of the matrices S and P. N >= 0.

S Input parameter.

S is COMPLEX

S is an array, dimension (LDS, N). The upper triangular matrix S from a generalized Schur factorization, as computed by CHGEQZ.

LDS Input parameter.

LDS is INTEGER

The leading dimension of array S. LDS >= max(1, N).

P Input parameter.

P is COMPLEX

P is an array, dimension (LDP, N). The upper triangular matrix P from a generalized Schur factorization, as computed by CHGEQZ. P must have real diagonal elements.

LDP Input parameter.

LDP is INTEGER

The leading dimension of array P. LDP >= max(1, N).

VL Input and output parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, MM). On entry, if SIDE = ‘L’ or ‘B’ and HOWMNY = ‘B’, VL must contain an N-by-N matrix Q (usually the unitary matrix Q of left Schur vectors returned by CHGEQZ). On exit, if SIDE = ‘L’ or ‘B’, VL contains: if HOWMNY = ‘A’, the matrix Y of left eigenvectors of (S, P); if HOWMNY = ‘B’, the matrix Q*Y; if HOWMNY = ‘S’, the left eigenvectors of (S, P) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. Not referenced if SIDE = ‘R’.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of array VL. LDVL >= 1, and if SIDE = ‘L’ or ‘l’ or ‘B’ or ‘b’, LDVL >= N.

VR Input and output parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, MM). On entry, if SIDE = ‘R’ or ‘B’ and HOWMNY = ‘B’, VR must contain an N-by-N matrix Q (usually the unitary matrix Z of right Schur vectors returned by CHGEQZ). On exit, if SIDE = ‘R’ or ‘B’, VR contains: if HOWMNY = ‘A’, the matrix X of right eigenvectors of (S, P); if HOWMNY = ‘B’, the matrix Z*X; if HOWMNY = ‘S’, the right eigenvectors of (S, P) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. Not referenced if SIDE = ‘L’.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dtgevc*, *stgevc* and *ztgevc*. It also exists with a native C interface as *LAPACKE_ctgevc*.

4.14.13 ctgexc

ctgexc reorders the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation (A, B) := Q * (A, B) * Z^H , so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)**H = Q(out) * A(out) * Z(out)**H
Q(in) * B(in) * Z(in)**H = Q(out) * B(out) * Z(out)**H
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ctgexc(WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, IFST, ILST,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ctgexc_(const armpl_int_t *wantq, const armpl_int_t *wantz,
             const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *q,
             const armpl_int_t *ldq, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, const armpl_int_t *ifst,
             armpl_int_t *ilst, armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the upper triangular matrix A in the pair (A, B). On exit, the updated matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the upper triangular matrix B in the pair (A, B). On exit, the updated matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., the unitary matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). On entry, if WANTZ = .TRUE., the unitary matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

IFST Input parameter.

IFST is INTEGER

ILST Input and output parameter.

ILST is INTEGER

Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks.

INFO Output parameter.

INFO is INTEGER

=0: Successful exit. <0: if INFO = -i, the i-th argument had an illegal value. =1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill- conditioned. (A, B) may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

Related Information

For this routine in other precisions, please see *dtgexc*, *stgexc* and *ztgexc*. It also exists with a native C interface as *LAPACKE_ctgexc*.

4.14.14 ctgsen

ctgsen reorders the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence trans- formation Q^H * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B). The leading columns of Q and Z form unitary bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ctgsen also computes the generalized eigenvalues

```
w(j)= ALPHA(j) / BETA(j)
```

of the reordered matrix pair (A, B).

Optionally, the routine computes estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctgsen(IJOB, WANTQ, WANTZ, SELECT, N, A, LDA, B, LDB, ALPHA, BETA,
                  Q, LDQ, Z, LDZ, M, PL, PR, DIF, WORK, LWORK, IWORK, LIWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ctgsen_(const armpl_int_t *ijob, const armpl_int_t *wantq,
             const armpl_int_t *wantz, const armpl_int_t *select,
             const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *alpha,
             armpl_singlecomplex_t *beta, armpl_singlecomplex_t *q,
             const armpl_int_t *ldq, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, armpl_int_t *m, float *pl, float *pr,
             float *dif, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info);
```

Parameters

IJOB Input parameter.

IJOB is INTEGER

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl): =0: Only reorder w.r.t. SELECT. No extras. =1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate (DIF(1:2)). =3: Estimate of Difu and Difl. 1-norm-based estimate (DIF(1:2)). About 5 times as expensive as IJOB = 2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). SELECT specifies the eigenvalues in the selected cluster. To select an eigenvalue w(j), SELECT(j) must be set to .TRUE..

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension(LDA, N). On entry, the upper triangular matrix A, in generalized Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension(LDB, N). On entry, the upper triangular matrix B, in generalized Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX

BETA is an array, dimension (N). The diagonal elements of A and B, respectively, when the pair (A, B) has been reduced to generalized Schur form. ALPHA(i)/BETA(i) i=1,. . . ,N are the generalized eigenvalues.

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

M Output parameter.

M is INTEGER

The dimension of the specified pair of left and right eigenspaces, (deflating subspaces) 0 <= M <= N.

PL Output parameter.

PL is REAL

PR Output parameter.

PR is REAL

If IJOB = 1, 4 or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspace with respect to the selected cluster. 0 < PL, PR <= 1. If M = 0 or M = N, PL = PR = 1. If IJOB = 0, 2 or 3 PL, PR are not referenced.

DIF Output parameter.

DIF is REAL

DIF is an array, dimension (2).. If IJOB >= 2, DIF(1:2) store the estimates of Difu and Difl. If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl, computed using reversed communication with CLACN2. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1 If IJOB = 1, 2 or 4, LWORK >= 2*M*(N-M) If IJOB = 3 or 5, LWORK >= 4*M*(N-M)

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= 1. If IJOB = 1, 2 or 4, LIWORK >= N+2; If IJOB = 3 or 5, LIWORK >= MAX(N+2, 2*M*(N-M));

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

=0: Successful exit. <0: If INFO = -i, the i-th argument had an illegal value. =1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

Related Information

For this routine in other precisions, please see *dtgsen*, *stgsen* and *ztgsen*. It also exists with a native C interface as *LAPACKE_ctgsen*.

4.14.15 ctgsna

ctgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B).

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctgsna(JOB, HOWMNY, SELECT, N, A, LDA, B, LDB, VL, LDVL, VR, LDVR,
                  S, DIF, MM, M, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctgsna_(const char *job, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, const armpl_singlecomplex_t *vl,
             const armpl_int_t *ldvl, const armpl_singlecomplex_t *vr,
             const armpl_int_t *ldvr, float *s, float *dif,
             const armpl_int_t *mm, armpl_int_t *m,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF): = 'E': for eigenvalues only (S); = 'V': for eigenvectors only (DIF); = 'B': for both eigenvalues and eigenvectors (S and DIF).

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute condition numbers for all eigenpairs; = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the corresponding j-th eigenvalue and/or eigenvector, SELECT(j) must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N Input parameter.

N is INTEGER

The order of the square matrix pair (A, B). N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The upper triangular matrix A in the pair (A, B).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, N). The upper triangular matrix B in the pair (A, B).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

VL Input parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, M). IF JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CTGEVC. If JOB = 'V', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; and If JOB = 'E' or 'B', LDVL >= N.

VR Input parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, M). IF JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CTGEVC. If JOB = 'V', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; If JOB = 'E' or 'B', LDVR >= N.

S Output parameter.

S is REAL

S is an array, dimension (MM). If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If JOB = 'V', S is not referenced.

DIF Output parameter.

DIF is REAL

DIF is an array, dimension (MM). If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. For each eigenvalue/vector specified by SELECT, DIF stores a Frobenius norm-based estimate of Difl. If JOB = 'E', DIF is not referenced.

MM Input parameter.

MM is INTEGER

The number of elements in the arrays S and DIF. MM >= M.

M Output parameter.

M is INTEGER

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected eigenvalue one element is used. If HOWMNY = 'A', M is set to N.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). If JOB = 'V' or 'B', LWORK >= max(1,2*N*N).

IWORK Output parameter.

IWORK is INTEGER array, dimension (N+2)

If JOB = 'E', IWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit < 0: If INFO = -i, the i-th argument had an illegal value

4.14.16 ctgsyl

ctgsyl solves the generalized Sylvester equation:

```
A * R - L * B = scale * C            (1)
D * R - L * E = scale * F
```

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with complex entries. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve Zx = scale*b, where Z is defined as

```
Z = [ kron(In, A)  -kron(B**H, Im) ]         (2)
    [ kron(In, D)  -kron(E**H, Im) ],
```

Here Ix is the identity matrix of size x and X^H is the conjugate transpose of X. Kron(X, Y) is the Kronecker product between the matrices X and Y.

If TRANS = 'C', y in the conjugate transposed system Z^H *y = scale*b is solved for, which is equivalent to solve for R and L in

```
A**H * R + D**H * L = scale * C           (3)
R * B**H + L * E**H = scale * -F
```

This case (TRANS = 'C') is used to compute an one-norm-based estimate of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D) and (B,E), using CLACON.

If IJOB >= 1, `ctgsyl` computes a Frobenius norm-based estimate of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z.

This is a level-3 BLAS algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctgsyl(TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD, E, LDE,
                  F, LDF, SCALE, DIF, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctgsyl_(const char *trans, const armpl_int_t *ijob, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, const armpl_singlecomplex_t *d,
             const armpl_int_t *ldd, const armpl_singlecomplex_t *e,
             const armpl_int_t *lde, armpl_singlecomplex_t *f,
             const armpl_int_t *ldf, float *scale, float *dif,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': solve the generalized sylvester equation (1). = 'C': solve the "conjugate transposed" system (3).

IJOB Input parameter.

IJOB is INTEGER

Specifies what kind of functionality to be performed. =0: solve (1) only. =1: The functionality of 0 and 3. =2: The functionality of 0 and 4. =3: Only an estimate of Dif[(A, D), (B, E)] is computed. (look ahead strategy is used). =4: Only an estimate of Dif[(A, D), (B, E)] is computed. (CGECON on sub-systems is used). Not referenced if TRANS = 'C'.

M Input parameter.

M is INTEGER

The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N Input parameter.

N is INTEGER

The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, M). The upper triangular matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, N). The upper triangular matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

D Input parameter.

D is COMPLEX

D is an array, dimension (LDD, M). The upper triangular matrix D.

LDD Input parameter.

LDD is INTEGER

The leading dimension of the array D. LDD >= max(1, M).

E Input parameter.

E is COMPLEX

E is an array, dimension (LDE, N). The upper triangular matrix E.

LDE Input parameter.

LDE is INTEGER

The leading dimension of the array E. LDE >= max(1, N).

F Input and output parameter.

F is COMPLEX

F is an array, dimension (LDF, N). On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the array F. LDF >= max(1, M).

DIF Output parameter.

DIF is REAL

On exit DIF is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. DIF is an upper bound of Dif[(A, D), (B, E)] = sigma-min(Z), where Z as in (2). IF IJOB = 0 or TRANS = 'C', DIF is not referenced.

SCALE Output parameter.

SCALE is REAL

On exit SCALE is the scaling factor in (1) or (3). If 0 < SCALE < 1, C and F hold the solutions R and L, resp., to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If SCALE = 0, R and L will hold the solutions to the homogenious system with C = F = 0.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK > = 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= max(1,2*M*N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M+N+2)

INFO Output parameter.

INFO is INTEGER

=0: successful exit <0: If INFO = -i, the i-th argument had an illegal value. >0: (A, D) and (B, E) have common or very close eigenvalues.

Related Information

For this routine in other precisions, please see *dtgsyl*, *stgsyl* and *ztgsyl*. It also exists with a native C interface as *LAPACKE_ctgsyl*.

4.14.17 dggbak

dggbak forms the right or left eigenvectors of a real generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by DGGBAL.

Syntax

Fortran specification:

```
use armpl_library

subroutine dggbak(JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V, LDV, INFO)
```

C specification:

```
#include "armpl.h"

void dggbak_(const char *job, const char *side, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             const double *lscale, const double *rscale, const armpl_int_t *m,
             double *v, const armpl_int_t *ldv, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the type of backward transformation required: = 'N': do nothing, return immediately; = 'P': do backward transformation for permutation only; = 'S': do backward transformation for scaling only; = 'B': do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to DGGBAL.

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': V contains right eigenvectors; = 'L': V contains left eigenvectors.

N Input parameter.

N is INTEGER

The number of rows of the matrix V. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

The integers ILO and IHI determined by DGGBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

LSCALE Input parameter.

LSCALE is DOUBLE PRECISION

LSCALE is an array, dimension (N). Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by DGGBAL.

RSCALE Input parameter.

RSCALE is DOUBLE PRECISION

RSCALE is an array, dimension (N). Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by DGGBAL.

M Input parameter.

M is INTEGER

The number of columns of the matrix V. M >= 0.

V Input and output parameter.

V is DOUBLE PRECISION

V is an array, dimension (LDV, M). On entry, the matrix of right or left eigenvectors to be transformed, as returned by DTGEVC. On exit, V is overwritten by the transformed eigenvectors.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the matrix V. LDV >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggbak*, *sggbak* and *zggbak*. It also exists with a native C interface as *LAPACKE_dggbak*.

4.14.18 dggbal

dggbal balances a pair of general real matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem A*x = lambda*B*x.

Syntax

Fortran specification:

```
use armpl_library

subroutine dggbal(JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dggbal_(const char *job, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
             armpl_int_t *ilo, armpl_int_t *ihi, double *lscale,
             double *rscale, double *work, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the operations to be performed on A and B: = 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i = 1,...,N. = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are set to integers such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,. . . ,ILO-1 or i = IHI+1,. . . ,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE Output parameter.

LSCALE is DOUBLE PRECISION

LSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then LSCALE(j) = P(j) for J = 1,. . . ,ILO-1 = D(j) for J = ILO,. . . ,IHI = P(j) for J = IHI+1,. . . ,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE Output parameter.

RSCALE is DOUBLE PRECISION

RSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then LSCALE(j) = P(j) for J = 1,. . . ,ILO-1 = D(j) for J = ILO,. . . ,IHI = P(j) for J = IHI+1,. . . ,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (lwork). lwork must be at least max(1,6*N) when JOB = 'S' or 'B', and at least 1 when JOB = 'N' or 'P'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggbal*, *sggbal* and *zggbal*. It also exists with a native C interface as *LAPACKE_dggbal*.

4.14.19 dgges

`dgges` computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T )
```

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T.The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver DGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
[  a  0  ]
[  0  b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgges(JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB, SDIM,
                 ALPHAR, ALPHAI, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK,
                 BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgges_(const char *jobvsl, const char *jobvsr, const char *sort,
            ARMPL_DGGES_DELCTG delctg, const armpl_int_t *n, double *a,
            const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
            armpl_int_t *sdim, double *alphar, double *alphai, double *beta,
            double *vsl, const armpl_int_t *ldvsl, double *vsr,
            const armpl_int_t *ldvsr, double *work, const armpl_int_t *lwork,
            armpl_int_t *bwork, armpl_int_t *info, ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG);

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of three DOUBLE PRECISION arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j), BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2 in this case.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR Output parameter.

ALPHAR is DOUBLE PRECISION

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is DOUBLE PRECISION

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A, B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is DOUBLE PRECISION

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is DOUBLE PRECISION

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N = 0, LWORK >= 1, else LWORK >= 8*N+16. For good performance , LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in DHGEQZ. =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in DTGSEN.

Related Information

For this routine in other precisions, please see *cgges*, *sgges* and *zgges*. It also exists with a native C interface as *LAPACKE_dgges*.

4.14.20 dgges3

dgges3 computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T )
```

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T.The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver DGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
[  a  0  ]
[  0  b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgges3(JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB, SDIM,
                  ALPHAR, ALPHAI, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK,
                  BWORK, INFO)
```

C specification:

```
#include "armpl.h"

            armpl_int_t *bwork, armpl_int_t *info, ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG);

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of three DOUBLE PRECISION arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j), BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2 in this case.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR Output parameter.

ALPHAR is DOUBLE PRECISION

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is DOUBLE PRECISION

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A, B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is DOUBLE PRECISION

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is DOUBLE PRECISION

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in DHGEQZ. =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in DTGSEN.

Related Information

For this routine in other precisions, please see *cgges3*, *sgges3* and *zgges3*. It also exists with a native C interface as *LAPACKE_dgges3*.

4.14.21 dggesx

dggesx computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL) S (VSR)**T, (VSL) T (VSR)**T )
```

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
[  a  0  ]
[  0  b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dggesx(JOBVSL, JOBVSR, SORT, SELCTG, SENSE, N, A, LDA, B, LDB,
                  SDIM, ALPHAR, ALPHAI, BETA, VSL, LDVSL, VSR, LDVSR, RCONDE,
                  RCONDV, WORK, LWORK, IWORK, LIWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dggesx_(const char *jobvsl, const char *jobvsr, const char *sort,
             ARMPL_DGGESX_DELCTG delctg, const char *sense,
             const armpl_int_t *n, double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, armpl_int_t *sdim,
             double *alphar, double *alphai, double *beta, double *vsl,
             const armpl_int_t *ldvsl, double *vsr, const armpl_int_t *ldvsr,
             double *rconde, double *rcondv, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *bwork, armpl_int_t *info,
             ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG).

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of three DOUBLE PRECISION arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N' : None are computed; = 'E' : Computed for average of selected eigenvalues only; = 'V' : Computed for selected deflating subspaces only; = 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR Output parameter.

ALPHAR is DOUBLE PRECISION

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is DOUBLE PRECISION

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A, B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is DOUBLE PRECISION

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is DOUBLE PRECISION

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

RCONDE Output parameter.

RCONDE is DOUBLE PRECISION

RCONDE is an array, dimension (2). If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV Output parameter.

RCONDV is DOUBLE PRECISION

RCONDV is an array, dimension (2). If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition numbers for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N = 0, LWORK >= 1, else if SENSE = 'E', 'V', or 'B', LWORK >= max(8*N, 6*N+16, 2*SDIM*(N-SDIM)), else LWORK >= max(8*N, 6*N+16). Note that 2*SDIM*(N-SDIM) <= N*N/2. Note also that an error is only returned if LWORK < max(8*N, 6*N+16), but if SENSE = 'E' or 'V' or 'B' this may not be large enough.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the WORK array and the minimum size of the IWORK array, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If SENSE = 'N' or N = 0, LIWORK >= 1, otherwise LIWORK >= N+6.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the WORK array and the minimum size of the IWORK array, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in DHGEQZ =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in DTGSEN.

4.14.22 dggev

dggev computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j).
```

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
u(j)**H * A  = lambda(j) * u(j)**H * B .
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine dggev(JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHAR, ALPHAI, BETA, VL,
                 LDVL, VR, LDVR, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dggev_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
            double *a, const armpl_int_t *lda, double *b,
            const armpl_int_t *ldb, double *alphar, double *alphai,
            double *beta, double *vl, const armpl_int_t *ldvl, double *vr,
            const armpl_int_t *ldvr, double *work, const armpl_int_t *lwork,
            armpl_int_t *info, ... );
```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHAR Output parameter.

ALPHAR is DOUBLE PRECISION

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is DOUBLE PRECISION

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector is scaled so the largest component has abs(real part)+abs(imag. part)=1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector is scaled so the largest component has abs(real part)+abs(imag. part)=1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,8*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in DHGEQZ. =N+2: error return from DTGEVC.

```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHAR Output parameter.

ALPHAR is DOUBLE PRECISION

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is DOUBLE PRECISION

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector is scaled so the largest component has abs(real part)+abs(imag. part)=1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector is scaled so the largest component has abs(real part)+abs(imag. part)=1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in DHGEQZ. =N+2: error return from DTGEVC.

4.14.24 dggevx

dggevx computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j) .
```

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
u(j)**H * A  = lambda(j) * u(j)**H * B.
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine dggevx(BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, B, LDB, ALPHAR,
                  ALPHAI, BETA, VL, LDVL, VR, LDVR, ILO, IHI, LSCALE, RSCALE,
                  ABNRM, BBNRM, RCONDE, RCONDV, WORK, LWORK, IWORK, BWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dggevx_(const char *balanc, const char *jobvl, const char *jobvr,
             const char *sense, const armpl_int_t *n, double *a,
             const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
             double *alphar, double *alphai, double *beta, double *vl,
             const armpl_int_t *ldvl, double *vr, const armpl_int_t *ldvr,
             armpl_int_t *ilo, armpl_int_t *ihi, double *lscale,
             double *rscale, double *abnrm, double *bbnrm, double *rconde,
             double *rcondv, double *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, armpl_int_t *bwork, armpl_int_t *info,
             ... );
```

Parameters

BALANC Input parameter.

BALANC is CHARACTER*1

Specifies the balance option to be performed. = 'N': do not diagonally scale or permute; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': none are computed; = 'E': computed for eigenvalues only; = 'V': computed for eigenvectors only; = 'B': computed for eigenvalues and eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the real Schur form of the "balanced" versions of the input A and B.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the real Schur form of the "balanced" versions of the input A and B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHAR Output parameter.

ALPHAR is DOUBLE PRECISION

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is DOUBLE PRECISION

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are integer values such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE Output parameter.

LSCALE is DOUBLE PRECISION

LSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1 = DL(j) for j = ILO,...,IHI = PL(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE Output parameter.

RSCALE is DOUBLE PRECISION

RSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1 = DR(j) for j = ILO,...,IHI = PR(j) for j = IHI+1,...,N The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM Output parameter.

ABNRM is DOUBLE PRECISION

The one-norm of the balanced matrix A.

BBNRM Output parameter.

BBNRM is DOUBLE PRECISION

The one-norm of the balanced matrix B.

RCONDE Output parameter.

RCONDE is DOUBLE PRECISION

RCONDE is an array, dimension (N). If SENSE = 'E' or 'B', the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of RCONDE are set to the same value. Thus RCONDE(j), RCONDV(j), and the j-th columns of VL and VR all correspond to the j-th eigenpair. If SENSE = 'N or 'V', RCONDE is not referenced.

RCONDV Output parameter.

RCONDV is DOUBLE PRECISION

RCONDV is an array, dimension (N). If SENSE = 'V' or 'B', the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of RCONDV are set to the same value. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'N' or 'E', RCONDV is not referenced.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). If BALANC = 'S' or 'B', or JOBVL = 'V', or JOBVR = 'V', LWORK >= max(1,6*N). If SENSE = 'E' or 'B', LWORK >= max(1,10*N). If SENSE = 'V' or 'B', LWORK >= 2*N*N+8*N+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N+6)

If SENSE = 'E', IWORK is not referenced.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). If SENSE = 'N', BWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in DHGEQZ. =N+2: error return from DTGEVC.

4.14.25 dgghd3

dgghd3 reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is

```
A*x = lambda*B*x,
```

and B is typically made upper triangular by computing its QR factorization and moving the orthogonal matrix Q to the left side of the equation.

This subroutine simultaneously reduces A to a Hessenberg matrix H:

```
Q**T*A*Z = H
```

and transforms B to another upper triangular matrix T:

```
Q**T*B*Z = T
```

in order to reduce the problem to its standard form

```
H*y = lambda*T*y
```

where y = Z^T *x.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

```
 Q1 * A * Z1**T = (Q1*Q) * H * (Z1*Z)**T

Q1 * B * Z1**T = (Q1*Q) * T * (Z1*Z)**T
```

If Q1 is the orthogonal matrix from the QR factorization of B in the original equation A*x = lambda*B*x, then `dgghd3` reduces the original problem to generalized Hessenberg form.

This is a blocked variant of DGGHRD, using matrix-matrix multiplications for parts of the computation to enhance performance.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgghd3(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgghd3_(const char *compq, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi, double *a,
             const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
             double *q, const armpl_int_t *ldq, double *z,
             const armpl_int_t *ldz, double *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'N': do not compute Q; = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'V': Q must contain an orthogonal matrix Q1 on entry, and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': do not compute Z; = 'I': Z is initialized to the unit matrix, and the orthogonal matrix Z is returned; = 'V': Z must contain an orthogonal matrix Z1 on entry, and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to DGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q^T B Z. The elements below the diagonal are set to zero.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the orthogonal matrix Q1, typically from the QR factorization of B. On exit, if COMPQ='I', the orthogonal matrix Q, and if COMPQ = 'V', the product Q1*Q. Not referenced if COMPQ='N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the orthogonal matrix Z1. On exit, if COMPZ='I', the orthogonal matrix Z, and if COMPZ = 'V', the product Z1*Z. Not referenced if COMPZ='N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1. For optimum performance LWORK >= 6*N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgghd3*, *sgghd3* and *zgghd3*. It also exists with a native C interface as *LAPACKE_dgghd3*.

4.14.26 dgghrd

dgghrd reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is

```
A*x = lambda*B*x,
```

and B is typically made upper triangular by computing its QR factorization and moving the orthogonal matrix Q to the left side of the equation.

This subroutine simultaneously reduces A to a Hessenberg matrix H:

```
Q**T*A*Z = H
```

and transforms B to another upper triangular matrix T:

```
Q**T*B*Z = T
```

in order to reduce the problem to its standard form

```
H*y = lambda*T*y
```

where y = Z^T *x.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

```
 Q1 * A * Z1**T = (Q1*Q) * H * (Z1*Z)**T

Q1 * B * Z1**T = (Q1*Q) * T * (Z1*Z)**T
```

If Q1 is the orthogonal matrix from the QR factorization of B in the original equation A*x = lambda*B*x, then dgghrd reduces the original problem to generalized Hessenberg form.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgghrd(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgghrd_(const char *compq, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi, double *a,
             const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
             double *q, const armpl_int_t *ldq, double *z,
             const armpl_int_t *ldz, armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'N': do not compute Q; = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'V': Q must contain an orthogonal matrix Q1 on entry, and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': do not compute Z; = 'I': Z is initialized to the unit matrix, and the orthogonal matrix Z is returned; = 'V': Z must contain an orthogonal matrix Z1 on entry, and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to DGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q^T B Z. The elements below the diagonal are set to zero.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the orthogonal matrix Q1, typically from the QR factorization of B. On exit, if COMPQ='I', the orthogonal matrix Q, and if COMPQ = 'V', the product Q1*Q. Not referenced if COMPQ='N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the orthogonal matrix Z1. On exit, if COMPZ='I', the orthogonal matrix Z, and if COMPZ = 'V', the product Z1*Z. Not referenced if COMPZ='N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgghrd*, *sgghrd* and *zgghrd*. It also exists with a native C interface as *LAPACKE_dgghrd*.

4.14.27 dhgeqz

dhgeqz computes the eigenvalues of a real matrix pair (H,T), where H is an upper Hessenberg matrix and T is upper triangular, using the double-shift QZ method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a real matrix pair (A,B):

```
A = Q1*H*Z1**T,  B = Q1*T*Z1**T,
```

as computed by DGGHRD.

If JOB='S', then the Hessenberg-triangular pair (H,T) is also reduced to generalized Schur form,

```
H = Q*S*Z**T,  T = Q*P*Z**T,
```

where Q and Z are orthogonal matrices, P is an upper triangular matrix, and S is a quasi-triangular matrix with 1-by-1 and 2-by-2 diagonal blocks.

The 1-by-1 blocks correspond to real eigenvalues of the matrix pair (H,T) and the 2-by-2 blocks correspond to complex conjugate pairs of eigenvalues.

Additionally, the 2-by-2 upper triangular diagonal blocks of P corresponding to 2-by-2 blocks of S are reduced to positive diagonal form, i.e., if S(j+1,j) is non-zero, then P(j+1,j) = P(j,j+1) = 0, P(j,j) > 0, and P(j+1,j+1) > 0.

Optionally, the orthogonal matrix Q from the generalized Schur factorization may be postmultiplied into an input matrix Q1, and the orthogonal matrix Z may be postmultiplied into an input matrix Z1. If Q1 and Z1 are the orthogonal matrices from DGGHRD that reduced the matrix pair (A,B) to generalized upper Hessenberg form, then the output matrices Q1*Q and Z1*Z are the orthogonal factors from the generalized Schur factorization of (A,B):

```
A = (Q1*Q)*S*(Z1*Z)**T,  B = (Q1*Q)*P*(Z1*Z)**T.
```

To avoid overflow, eigenvalues of the matrix pair (H,T) (equivalently, of (A,B)) are computed as a pair of values (alpha,beta), where alpha is complex and beta real. If beta is nonzero, lambda = alpha / beta is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

```
A*x = lambda*B*x
```

and if alpha is nonzero, mu = beta / alpha is an eigenvalue of the alternate form of the GNEP

```
mu*A*y = B*y.
```

Real eigenvalues can be read directly from the generalized Schur form:

```
alpha = S(i,i), beta = P(i,i).
```

Ref: C.B. Moler & G.W. Stewart, “An Algorithm for Generalized Matrix Eigenvalue Problems”, SIAM J. Numer. Anal., 10(1973), pp. 241–256.

Syntax

Fortran specification:

```
use armpl_library

subroutine dhgeqz(JOB, COMPQ, COMPZ, N, ILO, IHI, H, LDH, T, LDT, ALPHAR,
                  ALPHAI, BETA, Q, LDQ, Z, LDZ, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dhgeqz_(const char *job, const char *compq, const char *compz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, double *h, const armpl_int_t *ldh,
             double *t, const armpl_int_t *ldt, double *alphar,
             double *alphai, double *beta, double *q, const armpl_int_t *ldq,
             double *z, const armpl_int_t *ldz, double *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

= ‘E’: Compute eigenvalues only; = ‘S’: Compute eigenvalues and the Schur form.

COMPQ Input parameter.

COMPQ is CHARACTER*1

= ‘N’: Left Schur vectors (Q) are not computed; = ‘I’: Q is initialized to the unit matrix and the matrix Q of left Schur vectors of (H, T) is returned; = ‘V’: Q must contain an orthogonal matrix Q1 on entry and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= ‘N’: Right Schur vectors (Z) are not computed; = ‘I’: Z is initialized to the unit matrix and the matrix Z of right Schur vectors of (H, T) is returned; = ‘V’: Z must contain an orthogonal matrix Z1 on entry and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices H, T, Q, and Z. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of H which are in Hessenberg form. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. If N > 0, 1 <= ILO <= IHI <= N; if N = 0, ILO=1 and IHI=0.

H Input and output parameter.

H is DOUBLE PRECISION

H is an array, dimension (LDH, N). On entry, the N-by-N upper Hessenberg matrix H. On exit, if JOB = 'S', H contains the upper quasi-triangular matrix S from the generalized Schur factorization. If JOB = 'E', the diagonal blocks of H match those of S, but the rest of H is unspecified.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

T Input and output parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). On entry, the N-by-N upper triangular matrix T. On exit, if JOB = 'S', T contains the upper triangular matrix P from the generalized Schur factorization; 2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S are reduced to positive diagonal form, i.e., if H(j+1,j) is non-zero, then T(j+1,j) = T(j,j+1) = 0, T(j,j) > 0, and T(j+1,j+1) > 0. If JOB = 'E', the diagonal blocks of T match those of P, but the rest of T is unspecified.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

ALPHAR Output parameter.

ALPHAR is DOUBLE PRECISION

ALPHAR is an array, dimension (N). The real parts of each scalar alpha defining an eigenvalue of GNEP.

ALPHAI Output parameter.

ALPHAI is DOUBLE PRECISION

ALPHAI is an array, dimension (N). The imaginary parts of each scalar alpha defining an eigenvalue of GNEP. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) = -ALPHAI(j).

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). The scalars beta that define the eigenvalues of GNEP. Together, the quantities alpha = (ALPHAR(j),ALPHAI(j)) and beta = BETA(j) represent the j-th eigenvalue of the matrix pair (A,B), in one of the forms lambda = alpha/beta or mu = beta/alpha. Since either lambda or mu may overflow, they should not, in general, be computed.

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the orthogonal matrix Q1 used in the reduction of (A,B) to generalized Hessenberg form. On exit, if COMPQ = 'I', the orthogonal matrix of left Schur vectors

of (H, T), and if COMPQ = 'V', the orthogonal matrix of left Schur vectors of (A,B). Not referenced if COMPQ = 'N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If COMPQ='V' or 'I', then LDQ >= N.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the orthogonal matrix Z1 used in the reduction of (A,B) to generalized Hessenberg form. On exit, if COMPZ = 'I', the orthogonal matrix of right Schur vectors of (H, T), and if COMPZ = 'V', the orthogonal matrix of right Schur vectors of (A,B). Not referenced if COMPZ = 'N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If COMPZ='V' or 'I', then LDZ >= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1,...,N: the QZ iteration did not converge. (H, T) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (H, T) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO-N+1,...,N should be correct.

4.14.28 dtgevc

dtgevc computes some or all of the right and/or left eigenvectors of a pair of real matrices (S,P), where S is a quasi-triangular matrix and P is upper triangular. Matrix pairs of this type are produced by the generalized Schur factorization of a matrix pair (A,B):

```
A = Q*S*Z**T,  B = Q*P*Z**T
```

as computed by DGGHRD + DHGEQZ.

The right eigenvector x and the left eigenvector y of (S,P) corresponding to an eigenvalue w are defined by:

```
S*x = w*P*x,   (y**H)*S = w*(y**H)*P,
```

where y^H denotes the conjugate tranpose of y. The eigenvalues are not input to this routine, but are computed directly from the diagonal blocks of S and P.

This routine returns the matrices X and/or Y of right and left eigenvectors of (S,P), or the products Z*X and/or Q*Y, where Z and Q are input matrices. If Q and Z are the orthogonal factors from the generalized Schur factorization of a matrix pair (A,B), then Z*X and Q*Y are the matrices of right and left eigenvectors of (A,B).

Syntax

Fortran specification:

```
use armpl_library

subroutine dtgevc(SIDE, HOWMNY, SELECT, N, S, LDS, P, LDP, VL, LDVL, VR, LDVR,
                  MM, M, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtgevc_(const char *side, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const double *s, const armpl_int_t *lds,
             const double *p, const armpl_int_t *ldp, double *vl,
             const armpl_int_t *ldvl, double *vr, const armpl_int_t *ldvr,
             const armpl_int_t *mm, armpl_int_t *m, double *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed by the matrices in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If w(j) is a real eigenvalue, the corresponding real eigenvector is computed if SELECT(j) is .TRUE.. If w(j) and w(j+1) are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either SELECT(j) or SELECT(j+1) is .TRUE., and on exit SELECT(j) is set to .TRUE. and SELECT(j+1) is set to .FALSE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrices S and P. N >= 0.

S Input parameter.

S is DOUBLE PRECISION

S is an array, dimension (LDS, N). The upper quasi-triangular matrix S from a generalized Schur factorization, as computed by DHGEQZ.

LDS Input parameter.

LDS is INTEGER

The leading dimension of array S. LDS >= max(1, N).

P Input parameter.

P is DOUBLE PRECISION

P is an array, dimension (LDP, N). The upper triangular matrix P from a generalized Schur factorization, as computed by DHGEQZ. 2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S must be in positive diagonal form.

LDP Input parameter.

LDP is INTEGER

The leading dimension of array P. LDP >= max(1, N).

VL Input and output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of left Schur vectors returned by DHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (S, P); if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of (S, P) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of array VL. LDVL >= 1, and if SIDE = 'L' or 'B', LDVL >= N.

VR Input and output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Z (usually the orthogonal matrix Z of right Schur vectors returned by DHGEQZ).

On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (S, P); if HOWMNY = 'B' or 'b', the matrix Z*X; if HOWMNY = 'S' or 's', the right eigenvectors of (S, P) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part.

Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (6*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the 2-by-2 block (INFO:INFO+1) does not have a complex eigenvalue.

Related Information

For this routine in other precisions, please see *ctgevc*, *stgevc* and *ztgevc*. It also exists with a native C interface as *LAPACKE_dtgevc*.

4.14.29 dtgexc

dtgexc reorders the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation

```
(A, B) = Q * (A, B) * Z**T,
```

so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized real Schur canonical form (as returned by DGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)**T = Q(out) * A(out) * Z(out)**T
Q(in) * B(in) * Z(in)**T = Q(out) * B(out) * Z(out)**T
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dtgexc(WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, IFST, ILST,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtgexc_(const armpl_int_t *wantq, const armpl_int_t *wantz,
             const armpl_int_t *n, double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, double *q,
             const armpl_int_t *ldq, double *z, const armpl_int_t *ldz,
             armpl_int_t *ifst, armpl_int_t *ilst, double *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the matrix A in generalized real Schur canonical form. On exit, the updated matrix A, again in generalized real Schur canonical form.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the matrix B in generalized real Schur canonical form (A, B). On exit, the updated matrix B, again in generalized real Schur canonical form (A, B).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). On entry, if WANTZ = .TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

IFST Input and output parameter.

IFST is INTEGER

ILST Input and output parameter.

ILST is INTEGER

Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST, ILST <= N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1 when N <= 1, otherwise LWORK >= 4* N + 16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

=0: successful exit. <0: if INFO = -i, the i-th argument had an illegal value. =1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill- conditioned. (A, B) may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

Related Information

For this routine in other precisions, please see *ctgexc*, *stgexc* and *ztgexc*. It also exists with a native C interface as *LAPACKE_dtgexc*.

4.14.30 dtgsen

dtgsen reorders the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence trans- formation Q^T * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B. The leading columns of Q and Z form orthonormal bases of the corresponding left and right eigen- spaces (deflating subspaces). (A, B) must be in generalized real Schur canonical form (as returned by DGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

dtgsen also computes the generalized eigenvalues

```
w(j) = (ALPHAR(j) + i*ALPHAI(j))/BETA(j)
```

of the reordered matrix pair (A, B).

Optionally, dtgsen computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtgsen(IJOB, WANTQ, WANTZ, SELECT, N, A, LDA, B, LDB, ALPHAR,
                  ALPHAI, BETA, Q, LDQ, Z, LDZ, M, PL, PR, DIF, WORK, LWORK,
                  IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtgsen_(const armpl_int_t *ijob, const armpl_int_t *wantq,
             const armpl_int_t *wantz, const armpl_int_t *select,
             const armpl_int_t *n, double *a, const armpl_int_t *lda,
             double *b, const armpl_int_t *ldb, double *alphar,
             double *alphai, double *beta, double *q, const armpl_int_t *ldq,
             double *z, const armpl_int_t *ldz, armpl_int_t *m, double *pl,
             double *pr, double *dif, double *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, const armpl_int_t *liwork,
             armpl_int_t *info);
```

Parameters

IJOB Input parameter.

IJOB is INTEGER

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl): =0: Only reorder w.r.t. SELECT. No extras. =1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate (DIF(1:2)). =3: Estimate of Difu and Difl. 1-norm-based estimate (DIF(1:2)). About 5 times as expensive as IJOB = 2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select a complex conjugate pair of eigenvalues

w(j) and w(j+1), corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension(LDA, N). On entry, the upper quasi-triangular matrix A, with (A, B) in generalized real Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension(LDB, N). On entry, the upper triangular matrix B, with (A, B) in generalized real Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

ALPHAR Output parameter.

ALPHAR is DOUBLE PRECISION

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is DOUBLE PRECISION

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is DOUBLE PRECISION

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Q Input and output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; and if WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

M Output parameter.

M is INTEGER

The dimension of the specified pair of left and right eigen- spaces (deflating subspaces). 0 <= M <= N.

PL Output parameter.

PL is DOUBLE PRECISION

PR Output parameter.

PR is DOUBLE PRECISION

If IJOB = 1, 4 or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster. 0 < PL, PR <= 1. If M = 0 or M = N, PL = PR = 1. If IJOB = 0, 2 or 3, PL and PR are not referenced.

DIF Output parameter.

DIF is DOUBLE PRECISION

DIF is an array, dimension (2).. If IJOB >= 2, DIF(1:2) store the estimates of Difu and Difl. If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 4*N+16. If IJOB = 1, 2 or 4, LWORK >= MAX(4*N+16, 2*M*(N-M)). If IJOB = 3 or 5, LWORK >= MAX(4*N+16, 4*M*(N-M)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= 1. If IJOB = 1, 2 or 4, LIWORK >= N+6. If IJOB = 3 or 5, LIWORK >= MAX(2*M*(N-M), N+6).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

=0: Successful exit. <0: If INFO = -i, the i-th argument had an illegal value. =1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

Related Information

For this routine in other precisions, please see *ctgsen*, *stgsen* and *ztgsen*. It also exists with a native C interface as *LAPACKE_dtgsen*.

4.14.31 dtgsna

dtgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair ($Q*A*Z^T$, $Q*B*Z^T$) with orthogonal matrices Q and Z, where Z^T denotes the transpose of Z.

(A, B) must be in generalized real Schur form (as returned by DGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtgsna(JOB, HOWMNY, SELECT, N, A, LDA, B, LDB, VL, LDVL, VR, LDVR,
                  S, DIF, MM, M, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtgsna_(const char *job, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const double *a, const armpl_int_t *lda,
             const double *b, const armpl_int_t *ldb, const double *vl,
             const armpl_int_t *ldvl, const double *vr,
             const armpl_int_t *ldvr, double *s, double *dif,
             const armpl_int_t *mm, armpl_int_t *m, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF): = 'E': for eigenvalues only (S); = 'V': for eigenvectors only (DIF); = 'B': for both eigenvalues and eigenvectors (S and DIF).

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute condition numbers for all eigenpairs; = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues w(j) and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N Input parameter.

N is INTEGER

The order of the square matrix pair (A, B). N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The upper quasi-triangular matrix A in the pair (A, B).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). The upper triangular matrix B in the pair (A, B).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, M). If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by DTGEVC. If JOB = 'V', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1. If JOB = 'E' or 'B', LDVL >= N.

VR Input parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, M). If JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns ov VR, as returned by DTGEVC. If JOB = 'V', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1. If JOB = 'E' or 'B', LDVR >= N.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (MM). If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), DIF(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

DIF Output parameter.

DIF is DOUBLE PRECISION

DIF is an array, dimension (MM). If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of DIF are set to the same value. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', DIF is not referenced.

MM Input parameter.

MM is INTEGER

The number of elements in the arrays S and DIF. MM >= M.

M Output parameter.

M is INTEGER

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected real eigenvalue one element is used, and for each selected complex conjugate pair of eigenvalues, two elements are used. If HOWMNY = 'A', M is set to N.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). If JOB = 'V' or 'B' LWORK >= 2*N*(N+2)+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N + 6)

If JOB = 'E', IWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

=0: Successful exit <0: If INFO = -i, the i-th argument had an illegal value

4.14.32 dtgsyl

`dtgsyl` solves the generalized Sylvester equation:

```
A * R - L * B = scale * C                (1)
D * R - L * E = scale * F
```

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with real entries. (A, D) and (B, E) must be in generalized (real) Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve Zx = scale b, where Z is defined as

```
Z = [ kron(In, A)  -kron(B**T, Im) ]          (2)
    [ kron(In, D)  -kron(E**T, Im) ].
```

Here Ik is the identity matrix of size k and X^T is the transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y.

If TRANS = 'T', `dtgsyl` solves the transposed system Z^T *y = scale*b, which is equivalent to solve for R and L in

```
A**T * R + D**T * L = scale * C          (3)
R * B**T + L * E**T = scale * -F
```

This case (TRANS = 'T') is used to compute an one-norm-based estimate of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D) and (B,E), using DLACON.

If IJOB >= 1, `dtgsyl` computes a Frobenius norm-based estimate of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z. See [1-2] for more information.

This is a level 3 BLAS algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtgsyl(TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD, E, LDE,
                  F, LDF, SCALE, DIF, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtgsyl_(const char *trans, const armpl_int_t *ijob, const armpl_int_t *m,
             const armpl_int_t *n, const double *a, const armpl_int_t *lda,
             const double *b, const armpl_int_t *ldb, double *c,
             const armpl_int_t *ldc, const double *d, const armpl_int_t *ldd,
             const double *e, const armpl_int_t *lde, double *f,
             const armpl_int_t *ldf, double *scale, double *dif, double *work,
             const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N', solve the generalized Sylvester equation (1). = 'T', solve the 'transposed' system (3).

IJOB Input parameter.

IJOB is INTEGER

Specifies what kind of functionality to be performed. =0: solve (1) only. =1: The functionality of 0 and 3. =2: The functionality of 0 and 4. =3: Only an estimate of Dif[(A, D), (B, E)] is computed. (look ahead strategy IJOB = 1 is used). =4: Only an estimate of Dif[(A, D), (B, E)] is computed. (DGECON on sub-systems is used). Not referenced if TRANS = 'T'.

M Input parameter.

M is INTEGER

The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N Input parameter.

N is INTEGER

The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, M). The upper quasi triangular matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). The upper quasi triangular matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

C Input and output parameter.

C is DOUBLE PRECISION

C is an array, dimension (LDC, N). On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (LDD, M). The upper triangular matrix D.

LDD Input parameter.

LDD is INTEGER

The leading dimension of the array D. LDD >= max(1, M).

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (LDE, N). The upper triangular matrix E.

LDE Input parameter.

LDE is INTEGER

The leading dimension of the array E. LDE >= max(1, N).

F Input and output parameter.

F is DOUBLE PRECISION

F is an array, dimension (LDF, N). On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the array F. LDF >= max(1, M).

DIF Output parameter.

DIF is DOUBLE PRECISION

On exit DIF is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. DIF is an upper bound of Dif[(A, D), (B, E)] = sigma_min(Z), where Z as in (2). IF IJOB = 0 or TRANS = 'T', DIF is not touched.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

On exit SCALE is the scaling factor in (1) or (3). If 0 < SCALE < 1, C and F hold the solutions R and L, resp., to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If SCALE = 0, C and F hold the solutions R and L, respectively, to the homogeneous system with C = F = 0. Normally, SCALE = 1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK > = 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= max(1,2*M*N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M+N+6)

INFO Output parameter.

INFO is INTEGER

=0: successful exit <0: If INFO = -i, the i-th argument had an illegal value. >0: (A, D) and (B, E) have common or close eigenvalues.

Related Information

For this routine in other precisions, please see *ctgsyl*, *stgsyl* and *ztgsyl*. It also exists with a native C interface as *LAPACKE_dtgsyl*.

4.14.33 sggbak

`sggbak` forms the right or left eigenvectors of a real generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL.

Syntax

Fortran specification:

```
use armpl_library

subroutine sggbak(JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V, LDV, INFO)
```

C specification:

```
#include "armpl.h"

void sggbak_(const char *job, const char *side, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             const float *lscale, const float *rscale, const armpl_int_t *m,
             float *v, const armpl_int_t *ldv, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

`JOB` is `CHARACTER*1`

Specifies the type of backward transformation required: = 'N': do nothing, return immediately; = 'P': do backward transformation for permutation only; = 'S': do backward transformation for scaling only; = 'B': do backward transformations for both permutation and scaling. `JOB` must be the same as the argument `JOB` supplied to SGGBAL.

SIDE Input parameter.

`SIDE` is `CHARACTER*1`

= 'R': `V` contains right eigenvectors; = 'L': `V` contains left eigenvectors.

N Input parameter.

`N` is `INTEGER`

The number of rows of the matrix `V`. `N` >= 0.

ILO Input parameter.

`ILO` is `INTEGER`

IHI Input parameter.

`IHI` is `INTEGER`

The integers `ILO` and `IHI` determined by SGGBAL. 1 <= `ILO` <= `IHI` <= `N`, if `N` > 0; ILO=1 and IHI=0, if N=0.

LSCALE Input parameter.

LSCALE is REAL

LSCALE is an array, dimension (N). Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by SGGBAL.

RSCALE Input parameter.

RSCALE is REAL

RSCALE is an array, dimension (N). Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by SGGBAL.

M Input parameter.

M is INTEGER

The number of columns of the matrix V. M >= 0.

V Input and output parameter.

V is REAL

V is an array, dimension (LDV, M). On entry, the matrix of right or left eigenvectors to be transformed, as returned by STGEVC. On exit, V is overwritten by the transformed eigenvectors.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the matrix V. LDV >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggbak*, *dggbak* and *zggbak*. It also exists with a native C interface as *LAPACKE_sggbak*.

4.14.34 sggbal

sggbal balances a pair of general real matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem A*x = lambda*B*x.

Syntax

Fortran specification:

```
use armpl_library

subroutine sggbal(JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sggbal_(const char *job, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
             armpl_int_t *ilo, armpl_int_t *ihi, float *lscale, float *rscale,
             float *work, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the operations to be performed on A and B: = 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i = 1,...,N. = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are set to integers such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE Output parameter.

LSCALE is REAL

LSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then LSCALE(j) = P(j) for J = 1,...,ILO-1 = D(j) for J = ILO,...,IHI = P(j) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE Output parameter.

RSCALE is REAL

RSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then LSCALE(j) = P(j) for J = 1,...,ILO-1 = D(j) for J = ILO,...,IHI = P(j) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (lwork). lwork must be at least max(1,6*N) when JOB = 'S' or 'B', and at least 1 when JOB = 'N' or 'P'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggbal*, *dggbal* and *zggbal*. It also exists with a native C interface as *LAPACKE_sggbal*.

4.14.35 sgges

sgges computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T )
```

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T.The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver SGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
[  a   0  ]
[  0   b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgges(JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB, SDIM,
                 ALPHAR, ALPHAI, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK,
                 BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgges_(const char *jobvsl, const char *jobvsr, const char *sort,
            ARMPL_SGGES_SELCTG selctg, const armpl_int_t *n, float *a,
            const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
            armpl_int_t *sdim, float *alphar, float *alphai, float *beta,
            float *vsl, const armpl_int_t *ldvsl, float *vsr,
            const armpl_int_t *ldvsr, float *work, const armpl_int_t *lwork,
            armpl_int_t *bwork, armpl_int_t *info, ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG);

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of three REAL arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j), BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2 in this case.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR Output parameter.

ALPHAR is REAL

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is REAL

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A, B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is REAL

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is REAL

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N = 0, LWORK >= 1, else LWORK >= max(8*N,6*N+16). For good performance , LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ. =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

Related Information

For this routine in other precisions, please see *cgges*, *dgges* and *zgges*. It also exists with a native C interface as *LAPACKE_sgges*.

4.14.36 sgges3

sgges3 computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T )
```

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T.The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver SGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
[  a  0  ]
[  0  b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgges3(JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB, SDIM,
                  ALPHAR, ALPHAI, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK,
                  BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgges3_(const char *jobvsl, const char *jobvsr, const char *sort,

```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG);

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of three REAL arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j), BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2 in this case.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR Output parameter.

ALPHAR is REAL

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is REAL

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A, B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is REAL

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is REAL

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ. =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

Related Information

For this routine in other precisions, please see *cgges3*, *dgges3* and *zgges3*. It also exists with a native C interface as *LAPACKE_sgges3*.

4.14.37 sggesx

sggesx computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL) S (VSR)**T, (VSL) T (VSR)**T )
```

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
[  a   0  ]
[  0   b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine sggesx(JOBVSL, JOBVSR, SORT, SELCTG, SENSE, N, A, LDA, B, LDB,
                  SDIM, ALPHAR, ALPHAI, BETA, VSL, LDVSL, VSR, LDVSR, RCONDE,
                  RCONDV, WORK, LWORK, IWORK, LIWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sggesx_(const char *jobvsl, const char *jobvsr, const char *sort,
             ARMPL_SGGESX_SELCTG selctg, const char *sense,
             const armpl_int_t *n, float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, armpl_int_t *sdim, float *alphar,
             float *alphai, float *beta, float *vsl, const armpl_int_t *ldvsl,
             float *vsr, const armpl_int_t *ldvsr, float *rconde,
             float *rcondv, float *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, const armpl_int_t *liwork,
             armpl_int_t *bwork, armpl_int_t *info, ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG).

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of three REAL arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N' : None are computed; = 'E' : Computed for average of selected eigenvalues only; = 'V' : Computed for selected deflating subspaces only; = 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR Output parameter.

ALPHAR is REAL

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is REAL

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A, B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is REAL

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is REAL

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

RCONDE Output parameter.

RCONDE is REAL

RCONDE is an array, dimension (2). If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV Output parameter.

RCONDV is REAL

RCONDV is an array, dimension (2). If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition numbers for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N = 0, LWORK >= 1, else if SENSE = 'E', 'V', or 'B', LWORK >= max(8*N, 6*N+16, 2*SDIM*(N-SDIM)), else LWORK >= max(8*N, 6*N+16). Note that 2*SDIM*(N-SDIM) <= N*N/2. Note also that an error is only returned if LWORK < max(8*N, 6*N+16), but if SENSE = 'E' or 'V' or 'B' this may not be large enough.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the WORK array and the minimum size of the IWORK array, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If SENSE = 'N' or N = 0, LIWORK >= 1, otherwise LIWORK >= N+6.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the WORK array and the minimum size of the IWORK array, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

4.14.38 sggev

sggev computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j).
```

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
u(j)**H * A  = lambda(j) * u(j)**H * B .
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine sggev(JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHAR, ALPHAI, BETA, VL,
                 LDVL, VR, LDVR, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sggev_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
            float *a, const armpl_int_t *lda, float *b,
            const armpl_int_t *ldb, float *alphar, float *alphai, float *beta,
            float *vl, const armpl_int_t *ldvl, float *vr,
            const armpl_int_t *ldvr, float *work, const armpl_int_t *lwork,
            armpl_int_t *info, ... );
```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHAR Output parameter.

ALPHAR is REAL

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is REAL

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is REAL

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector is scaled so the largest component has abs(real part)+abs(imag. part)=1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is REAL

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector is scaled so the largest component has abs(real part)+abs(imag. part)=1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,8*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ. =N+2: error return from STGEVC.

```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHAR Output parameter.

ALPHAR is REAL

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is REAL

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is REAL

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector is scaled so the largest component has abs(real part)+abs(imag. part)=1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is REAL

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector is scaled so the largest component has abs(real part)+abs(imag. part)=1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ. =N+2: error return from STGEVC.

4.14.40 sggevx

sggevx computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j) .
```

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
u(j)**H * A  = lambda(j) * u(j)**H * B.
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine sggevx(BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, B, LDB, ALPHAR,
                  ALPHAI, BETA, VL, LDVL, VR, LDVR, ILO, IHI, LSCALE, RSCALE,
                  ABNRM, BBNRM, RCONDE, RCONDV, WORK, LWORK, IWORK, BWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sggevx_(const char *balanc, const char *jobvl, const char *jobvr,
             const char *sense, const armpl_int_t *n, float *a,
             const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
             float *alphar, float *alphai, float *beta, float *vl,
             const armpl_int_t *ldvl, float *vr, const armpl_int_t *ldvr,
             armpl_int_t *ilo, armpl_int_t *ihi, float *lscale, float *rscale,
             float *abnrm, float *bbnrm, float *rconde, float *rcondv,
             float *work, const armpl_int_t *lwork, armpl_int_t *iwork,
             armpl_int_t *bwork, armpl_int_t *info, ... );
```

Parameters

BALANC Input parameter.

BALANC is CHARACTER*1

Specifies the balance option to be performed. = 'N': do not diagonally scale or permute; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': none are computed; = 'E': computed for eigenvalues only; = 'V': computed for eigenvectors only; = 'B': computed for eigenvalues and eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the real Schur form of the "balanced" versions of the input A and B.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the real Schur form of the "balanced" versions of the input A and B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHAR Output parameter.

ALPHAR is REAL

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is REAL

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is REAL

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is REAL

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are integer values such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE Output parameter.

LSCALE is REAL

LSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1 = DL(j) for j = ILO,...,IHI = PL(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE Output parameter.

RSCALE is REAL

RSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1 = DR(j) for j = ILO,...,IHI = PR(j) for j = IHI+1,...,N The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM Output parameter.

ABNRM is REAL

The one-norm of the balanced matrix A.

BBNRM Output parameter.

BBNRM is REAL

The one-norm of the balanced matrix B.

RCONDE Output parameter.

RCONDE is REAL

RCONDE is an array, dimension (N). If SENSE = 'E' or 'B', the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of RCONDE are set to the same value. Thus RCONDE(j), RCONDV(j), and the j-th columns of VL and VR all correspond to the j-th eigenpair. If SENSE = 'N' or 'V', RCONDE is not referenced.

RCONDV Output parameter.

RCONDV is REAL

RCONDV is an array, dimension (N). If SENSE = 'V' or 'B', the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of RCONDV are set to the same value. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'N' or 'E', RCONDV is not referenced.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). If BALANC = 'S' or 'B', or JOBVL = 'V', or JOBVR = 'V', LWORK >= max(1,6*N). If SENSE = 'E', LWORK >= max(1,10*N). If SENSE = 'V' or 'B', LWORK >= 2*N*N+8*N+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N+6)

If SENSE = 'E', IWORK is not referenced.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). If SENSE = 'N', BWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ. =N+2: error return from STGEVC.

4.14.41 sgghd3

sgghd3 reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is

```
A*x = lambda*B*x,
```

and B is typically made upper triangular by computing its QR factorization and moving the orthogonal matrix Q to the left side of the equation.

This subroutine simultaneously reduces A to a Hessenberg matrix H:

```
Q**T*A*Z = H
```

and transforms B to another upper triangular matrix T:

```
Q**T*B*Z = T
```

in order to reduce the problem to its standard form

```
H*y = lambda*T*y
```

where y = Z^T *x.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

```
Q1 * A * Z1**T = (Q1*Q) * H * (Z1*Z)**T

Q1 * B * Z1**T = (Q1*Q) * T * (Z1*Z)**T
```

If Q1 is the orthogonal matrix from the QR factorization of B in the original equation A*x = lambda*B*x, then `sgghd3` reduces the original problem to generalized Hessenberg form.

This is a blocked variant of SGGHRD, using matrix-matrix multiplications for parts of the computation to enhance performance.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgghd3(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgghd3_(const char *compq, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi, float *a,
             const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
             float *q, const armpl_int_t *ldq, float *z,
             const armpl_int_t *ldz, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

`COMPQ` is `CHARACTER*1`

= 'N': do not compute Q; = 'I': `Q` is initialized to the unit matrix, and the orthogonal matrix `Q` is returned; = 'V': `Q` must contain an orthogonal matrix Q1 on entry, and the product Q1* `Q` is returned.

COMPZ Input parameter.

`COMPZ` is `CHARACTER*1`

= 'N': do not compute Z; = 'I': `Z` is initialized to the unit matrix, and the orthogonal matrix `Z` is returned; = 'V': `Z` must contain an orthogonal matrix Z1 on entry, and the product Z1* `Z` is returned.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q^T B Z. The elements below the diagonal are set to zero.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the orthogonal matrix Q1, typically from the QR factorization of B. On exit, if COMPQ='I', the orthogonal matrix Q, and if COMPQ = 'V', the product Q1*Q. Not referenced if COMPQ='N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the orthogonal matrix Z1. On exit, if COMPZ='I', the orthogonal matrix Z, and if COMPZ = 'V', the product Z1*Z. Not referenced if COMPZ='N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1. For optimum performance LWORK >= 6*N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

4.14.42 sgghrd

sgghrd reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is

```
A*x = lambda*B*x,
```

and B is typically made upper triangular by computing its QR factorization and moving the orthogonal matrix Q to the left side of the equation.

This subroutine simultaneously reduces A to a Hessenberg matrix H:

```
Q**T*A*Z = H
```

and transforms B to another upper triangular matrix T:

```
Q**T*B*Z = T
```

in order to reduce the problem to its standard form

```
H*y = lambda*T*y
```

where y = Z^T *x.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

```
Q1 * A * Z1**T = (Q1*Q) * H * (Z1*Z)**T

Q1 * B * Z1**T = (Q1*Q) * T * (Z1*Z)**T
```

If Q1 is the orthogonal matrix from the QR factorization of B in the original equation A*x = lambda*B*x, then sgghrd reduces the original problem to generalized Hessenberg form.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgghrd(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgghrd_(const char *compq, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi, float *a,
             const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
             float *q, const armpl_int_t *ldq, float *z,
             const armpl_int_t *ldz, armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'N': do not compute Q; = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'V': Q must contain an orthogonal matrix Q1 on entry, and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': do not compute Z; = 'I': Z is initialized to the unit matrix, and the orthogonal matrix Z is returned; = 'V': Z must contain an orthogonal matrix Z1 on entry, and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q^T B Z. The elements below the diagonal are set to zero.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the orthogonal matrix Q1, typically from the QR factorization of B. On exit, if COMPQ='I', the orthogonal matrix Q, and if COMPQ = 'V', the product Q1*Q. Not referenced if COMPQ='N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the orthogonal matrix Z1. On exit, if COMPZ='I', the orthogonal matrix Z, and if COMPZ = 'V', the product Z1*Z. Not referenced if COMPZ='N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgghrd*, *dgghrd* and *zgghrd*. It also exists with a native C interface as *LAPACKE_sgghrd*.

4.14.43 shgeqz

shgeqz computes the eigenvalues of a real matrix pair (H,T), where H is an upper Hessenberg matrix and T is upper triangular, using the double-shift QZ method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a real matrix pair (A,B):

```
A = Q1*H*Z1**T,  B = Q1*T*Z1**T,
```

as computed by SGGHRD.

If JOB='S', then the Hessenberg-triangular pair (H,T) is also reduced to generalized Schur form,

```
H = Q*S*Z**T,  T = Q*P*Z**T,
```

where Q and Z are orthogonal matrices, P is an upper triangular matrix, and S is a quasi-triangular matrix with 1-by-1 and 2-by-2 diagonal blocks.

The 1-by-1 blocks correspond to real eigenvalues of the matrix pair (H,T) and the 2-by-2 blocks correspond to complex conjugate pairs of eigenvalues.

Additionally, the 2-by-2 upper triangular diagonal blocks of P corresponding to 2-by-2 blocks of S are reduced to positive diagonal form, i.e., if S(j+1,j) is non-zero, then P(j+1,j) = P(j,j+1) = 0, P(j,j) > 0, and P(j+1,j+1) > 0.

Optionally, the orthogonal matrix Q from the generalized Schur factorization may be postmultiplied into an input matrix Q1, and the orthogonal matrix Z may be postmultiplied into an input matrix Z1. If Q1 and Z1 are the orthogonal matrices from SGGHRD that reduced the matrix pair (A,B) to generalized upper Hessenberg form, then the output matrices Q1*Q and Z1*Z are the orthogonal factors from the generalized Schur factorization of (A,B):

```
A = (Q1*Q)*S*(Z1*Z)**T,  B = (Q1*Q)*P*(Z1*Z)**T.
```

To avoid overflow, eigenvalues of the matrix pair (H,T) (equivalently, of (A,B)) are computed as a pair of values (alpha,beta), where alpha is complex and beta real. If beta is nonzero, lambda = alpha / beta is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

```
A*x = lambda*B*x
```

and if alpha is nonzero, mu = beta / alpha is an eigenvalue of the alternate form of the GNEP

```
mu*A*y = B*y.
```

Real eigenvalues can be read directly from the generalized Schur form:

```
alpha = S(i,i), beta = P(i,i).
```

Ref: C.B. Moler & G.W. Stewart, “An Algorithm for Generalized Matrix Eigenvalue Problems”, SIAM J. Numer. Anal., 10(1973), pp. 241–256.

Syntax

Fortran specification:

```
use armpl_library

subroutine shgeqz(JOB, COMPQ, COMPZ, N, ILO, IHI, H, LDH, T, LDT, ALPHAR,
                  ALPHAI, BETA, Q, LDQ, Z, LDZ, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void shgeqz_(const char *job, const char *compq, const char *compz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, float *h, const armpl_int_t *ldh,
             float *t, const armpl_int_t *ldt, float *alphar, float *alphai,
             float *beta, float *q, const armpl_int_t *ldq, float *z,
             const armpl_int_t *ldz, float *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

= ‘E’: Compute eigenvalues only; = ‘S’: Compute eigenvalues and the Schur form.

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'N': Left Schur vectors (Q) are not computed; = 'I': Q is initialized to the unit matrix and the matrix Q of left Schur vectors of (H, T) is returned; = 'V': Q must contain an orthogonal matrix Q1 on entry and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Right Schur vectors (Z) are not computed; = 'I': Z is initialized to the unit matrix and the matrix Z of right Schur vectors of (H, T) is returned; = 'V': Z must contain an orthogonal matrix Z1 on entry and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices H, T, Q, and Z. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of H which are in Hessenberg form. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. If N > 0, 1 <= ILO <= IHI <= N; if N = 0, ILO=1 and IHI=0.

H Input and output parameter.

H is REAL

H is an array, dimension (LDH, N). On entry, the N-by-N upper Hessenberg matrix H. On exit, if JOB = 'S', H contains the upper quasi-triangular matrix S from the generalized Schur factorization. If JOB = 'E', the diagonal blocks of H match those of S, but the rest of H is unspecified.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

T Input and output parameter.

T is REAL

T is an array, dimension (LDT, N). On entry, the N-by-N upper triangular matrix T. On exit, if JOB = 'S', T contains the upper triangular matrix P from the generalized Schur factorization; 2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S are reduced to positive diagonal form, i.e., if H(j+1,j) is non-zero, then T(j+1,j) = T(j,j+1) = 0, T(j,j) > 0, and T(j+1,j+1) > 0. If JOB = 'E', the diagonal blocks of T match those of P, but the rest of T is unspecified.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

ALPHAR Output parameter.

ALPHAR is REAL

ALPHAR is an array, dimension (N). The real parts of each scalar alpha defining an eigenvalue of GNEP.

ALPHAI Output parameter.

ALPHAI is REAL

ALPHAI is an array, dimension (N). The imaginary parts of each scalar alpha defining an eigenvalue of GNEP. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) = -ALPHAI(j).

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). The scalars beta that define the eigenvalues of GNEP. Together, the quantities alpha = (ALPHAR(j),ALPHAI(j)) and beta = BETA(j) represent the j-th eigenvalue of the matrix pair (A,B), in one of the forms lambda = alpha/beta or mu = beta/alpha. Since either lambda or mu may overflow, they should not, in general, be computed.

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the orthogonal matrix Q1 used in the reduction of (A,B) to generalized Hessenberg form. On exit, if COMPQ = 'I', the orthogonal matrix of left Schur vectors of (H, T), and if COMPQ = 'V', the orthogonal matrix of left Schur vectors of (A,B). Not referenced if COMPQ = 'N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If COMPQ='V' or 'I', then LDQ >= N.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the orthogonal matrix Z1 used in the reduction of (A,B) to generalized Hessenberg form. On exit, if COMPZ = 'I', the orthogonal matrix of right Schur vectors of (H, T), and if COMPZ = 'V', the orthogonal matrix of right Schur vectors of (A,B). Not referenced if COMPZ = 'N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If COMPZ='V' or 'I', then LDZ >= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1,...,N: the QZ iteration did not converge. (H, T) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (H, T) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO-N+1,...,N should be correct.

Related Information

4.14.44 stgevc

`stgevc` computes some or all of the right and/or left eigenvectors of a pair of real matrices (S,P), where S is a quasi-triangular matrix and P is upper triangular. Matrix pairs of this type are produced by the generalized Schur factorization of a matrix pair (A,B):

```
A = Q*S*Z**T,  B = Q*P*Z**T
```

as computed by SGGHRD + SHGEQZ.

The right eigenvector x and the left eigenvector y of (S,P) corresponding to an eigenvalue w are defined by:

```
S*x = w*P*x,  (y**H)*S = w*(y**H)*P,
```

where y^H denotes the conjugate tranpose of y. The eigenvalues are not input to this routine, but are computed directly from the diagonal blocks of S and P.

This routine returns the matrices X and/or Y of right and left eigenvectors of (S,P), or the products Z*X and/or Q*Y, where Z and Q are input matrices. If Q and Z are the orthogonal factors from the generalized Schur factorization of a matrix pair (A,B), then Z*X and Q*Y are the matrices of right and left eigenvectors of (A,B).

Syntax

Fortran specification:

```
use armpl_library

subroutine stgevc(SIDE, HOWMNY, SELECT, N, S, LDS, P, LDP, VL, LDVL, VR, LDVR,
                  MM, M, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void stgevc_(const char *side, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const float *s, const armpl_int_t *lds,
             const float *p, const armpl_int_t *ldp, float *vl,
             const armpl_int_t *ldvl, float *vr, const armpl_int_t *ldvr,
             const armpl_int_t *mm, armpl_int_t *m, float *work,
             armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

`SIDE` is `CHARACTER*1`

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

`HOWMNY` is `CHARACTER*1`

= ‘A’: compute all right and/or left eigenvectors; = ‘B’: compute all right and/or left eigenvectors, backtransformed by the matrices in VR and/or VL; = ‘S’: compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY=’S’, SELECT specifies the eigenvectors to be computed. If w(j) is a real eigenvalue, the corresponding real eigenvector is computed if SELECT(j) is .TRUE.. If w(j) and w(j+1) are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either SELECT(j) or SELECT(j+1) is .TRUE., and on exit SELECT(j) is set to .TRUE. and SELECT(j+1) is set to .FALSE.. Not referenced if HOWMNY = ‘A’ or ‘B’.

N Input parameter.

N is INTEGER

The order of the matrices S and P. N >= 0.

S Input parameter.

S is REAL

S is an array, dimension (LDS, N). The upper quasi-triangular matrix S from a generalized Schur factorization, as computed by SHGEQZ.

LDS Input parameter.

LDS is INTEGER

The leading dimension of array S. LDS >= max(1, N).

P Input parameter.

P is REAL

P is an array, dimension (LDP, N). The upper triangular matrix P from a generalized Schur factorization, as computed by SHGEQZ. 2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S must be in positive diagonal form.

LDP Input parameter.

LDP is INTEGER

The leading dimension of array P. LDP >= max(1, N).

VL Input and output parameter.

VL is REAL

VL is an array, dimension (LDVL, MM). On entry, if SIDE = ‘L’ or ‘B’ and HOWMNY = ‘B’, VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of left Schur vectors returned by SHGEQZ). On exit, if SIDE = ‘L’ or ‘B’, VL contains: if HOWMNY = ‘A’, the matrix Y of left eigenvectors of (S, P); if HOWMNY = ‘B’, the matrix Q*Y; if HOWMNY = ‘S’, the left eigenvectors of (S, P) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

Not referenced if SIDE = ‘R’.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of array VL. LDVL >= 1, and if SIDE = ‘L’ or ‘B’, LDVL >= N.

VR Input and output parameter.

VR is REAL

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Z (usually the orthogonal matrix Z of right Schur vectors returned by SHGEQZ).

On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (S, P); if HOWMNY = 'B' or 'b', the matrix Z*X; if HOWMNY = 'S' or 's', the right eigenvectors of (S, P) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part.

Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (6*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: the 2-by-2 block (INFO:INFO+1) does not have a complex eigenvalue.

Related Information

For this routine in other precisions, please see *ctgevc*, *dtgevc* and *ztgevc*. It also exists with a native C interface as *LAPACKE_stgevc*.

4.14.45 stgexc

stgexc reorders the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation

```
(A, B) = Q * (A, B) * Z**T,
```

so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)**T = Q(out) * A(out) * Z(out)**T
Q(in) * B(in) * Z(in)**T = Q(out) * B(out) * Z(out)**T
```

Syntax

Fortran specification:

```
use armpl_library

subroutine stgexc(WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, IFST, ILST,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void stgexc_(const armpl_int_t *wantq, const armpl_int_t *wantz,
             const armpl_int_t *n, float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, float *q, const armpl_int_t *ldq,
             float *z, const armpl_int_t *ldz, armpl_int_t *ifst,
             armpl_int_t *ilst, float *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the matrix A in generalized real Schur canonical form. On exit, the updated matrix A, again in generalized real Schur canonical form.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the matrix B in generalized real Schur canonical form (A, B). On exit, the updated matrix B, again in generalized real Schur canonical form (A, B).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, if WANTZ = .TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

IFST Input and output parameter.

IFST is INTEGER

ILST Input and output parameter.

ILST is INTEGER

Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST, ILST <= N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1 when N <= 1, otherwise LWORK >= 4* N + 16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

=0: successful exit. <0: if INFO = -i, the i-th argument had an illegal value. =1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill- conditioned. (A, B) may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

Related Information

For this routine in other precisions, please see *ctgexc*, *dtgexc* and *ztgexc*. It also exists with a native C interface as *LAPACKE_stgexc*.

4.14.46 stgsen

`stgsen` reorders the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence trans- formation Q^T * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B. The leading columns of Q and Z form orthonormal bases of the corresponding left and right eigen- spaces (deflating subspaces). (A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

`stgsen` also computes the generalized eigenvalues

```
w(j) = (ALPHAR(j) + i*ALPHAI(j))/BETA(j)
```

of the reordered matrix pair (A, B).

Optionally, `stgsen` computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

Syntax

Fortran specification:

```
use armpl_library

subroutine stgsen(IJOB, WANTQ, WANTZ, SELECT, N, A, LDA, B, LDB, ALPHAR,
                  ALPHAI, BETA, Q, LDQ, Z, LDZ, M, PL, PR, DIF, WORK, LWORK,
                  IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void stgsen_(const armpl_int_t *ijob, const armpl_int_t *wantq,
             const armpl_int_t *wantz, const armpl_int_t *select,
             const armpl_int_t *n, float *a, const armpl_int_t *lda, float *b,
             const armpl_int_t *ldb, float *alphar, float *alphai,
             float *beta, float *q, const armpl_int_t *ldq, float *z,
             const armpl_int_t *ldz, armpl_int_t *m, float *pl, float *pr,
             float *dif, float *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, const armpl_int_t *liwork,
             armpl_int_t *info);
```

Parameters

IJOB Input parameter.

`IJOB` is `INTEGER`

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl): =0: Only reorder w.r.t. `SELECT`. No extras. =1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate (DIF(1:2)). =3: Estimate of Difu and Difl. 1-norm-based estimate (DIF(1:2)). About 5 times as expensive as `IJOB` = 2. =4: Compute `PL`, `PR` and `DIF` (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute `PL`, `PR` and `DIF` (i.e. 0, 1 and 3 above)

WANTQ Input parameter.

`WANTQ` is `LOGICAL`

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update `Q`.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select a complex conjugate pair of eigenvalues w(j) and w(j+1), corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension(LDA, N). On entry, the upper quasi-triangular matrix A, with (A, B) in generalized real Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension(LDB, N). On entry, the upper triangular matrix B, with (A, B) in generalized real Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

ALPHAR Output parameter.

ALPHAR is REAL

ALPHAR is an array, dimension (N) .

ALPHAI Output parameter.

ALPHAI is REAL

ALPHAI is an array, dimension (N) .

BETA Output parameter.

BETA is REAL

BETA is an array, dimension (N). On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Q Input and output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; and if WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

M Output parameter.

M is INTEGER

The dimension of the specified pair of left and right eigen- spaces (deflating subspaces). 0 <= M <= N.

PL Output parameter.

PL is REAL

PR Output parameter.

PR is REAL

If IJOB = 1, 4 or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster. 0 < PL, PR <= 1. If M = 0 or M = N, PL = PR = 1. If IJOB = 0, 2 or 3, PL and PR are not referenced.

DIF Output parameter.

DIF is REAL

DIF is an array, dimension (2).. If IJOB >= 2, DIF(1:2) store the estimates of Difu and Difl. If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 4*N+16. If IJOB = 1, 2 or 4, LWORK >= MAX(4*N+16, 2*M*(N-M)). If IJOB = 3 or 5, LWORK >= MAX(4*N+16, 4*M*(N-M)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= 1. If IJOB = 1, 2 or 4, LIWORK >= N+6. If IJOB = 3 or 5, LIWORK >= MAX(2*M*(N-M), N+6).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

=0: Successful exit. <0: If INFO = -i, the i-th argument had an illegal value. =1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

Related Information

For this routine in other precisions, please see *ctgsen*, *dtgsen* and *ztgsen*. It also exists with a native C interface as *LAPACKE_stgsen*.

4.14.47 stgsna

stgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair ($Q*A*Z^T$, $Q*B*Z^T$) with orthogonal matrices Q and Z, where Z^T denotes the transpose of Z.

(A, B) must be in generalized real Schur form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine stgsna(JOB, HOWMNY, SELECT, N, A, LDA, B, LDB, VL, LDVL, VR, LDVR,
                  S, DIF, MM, M, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void stgsna_(const char *job, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const float *a, const armpl_int_t *lda,
             const float *b, const armpl_int_t *ldb, const float *vl,
             const armpl_int_t *ldvl, const float *vr,
             const armpl_int_t *ldvr, float *s, float *dif,
             const armpl_int_t *mm, armpl_int_t *m, float *work,
             const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF): = 'E': for eigenvalues only (S); = 'V': for eigenvectors only (DIF); = 'B': for both eigenvalues and eigenvectors (S and DIF).

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute condition numbers for all eigenpairs; = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues w(j) and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N Input parameter.

N is INTEGER

The order of the square matrix pair (A, B). N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The upper quasi-triangular matrix A in the pair (A, B).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is REAL

B is an array, dimension (LDB, N). The upper triangular matrix B in the pair (A, B).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

VL Input parameter.

VL is REAL

VL is an array, dimension (LDVL, M). If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by STGEVC. If JOB = 'V', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1. If JOB = 'E' or 'B', LDVL >= N.

VR Input parameter.

VR is REAL

VR is an array, dimension (LDVR, M). If JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns ov VR, as returned by STGEVC. If JOB = 'V', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1. If JOB = 'E' or 'B', LDVR >= N.

S Output parameter.

S is REAL

S is an array, dimension (MM). If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), DIF(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

DIF Output parameter.

DIF is REAL

DIF is an array, dimension (MM). If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of DIF are set to the same value. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', DIF is not referenced.

MM Input parameter.

MM is INTEGER

The number of elements in the arrays S and DIF. MM >= M.

M Output parameter.

M is INTEGER

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected real eigenvalue one element is used, and for each selected complex conjugate pair of eigenvalues, two elements are used. If HOWMNY = 'A', M is set to N.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). If JOB = 'V' or 'B' LWORK >= 2*N*(N+2)+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N + 6)

If JOB = 'E', IWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

=0: Successful exit <0: If INFO = -i, the i-th argument had an illegal value

4.14.48 stgsyl

stgsyl solves the generalized Sylvester equation:

```
A * R - L * B = scale * C                (1)
D * R - L * E = scale * F
```

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with real entries. (A, D) and (B, E) must be in generalized (real) Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve Zx = scale b, where Z is defined as

```
Z = [ kron(In, A)  -kron(B**T, Im) ]          (2)
    [ kron(In, D)  -kron(E**T, Im) ].
```

Here Ik is the identity matrix of size k and X^T is the transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y.

If TRANS = 'T', stgsyl solves the transposed system Z^T *y = scale*b, which is equivalent to solve for R and L in

```
A**T * R + D**T * L = scale * C          (3)
R * B**T + L * E**T = scale * -F
```

This case (TRANS = 'T') is used to compute an one-norm-based estimate of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D) and (B,E), using SLACON.

If IJOB >= 1, stgsyl computes a Frobenius norm-based estimate of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z. See [1-2] for more information.

This is a level 3 BLAS algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine stgsyl(TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD, E, LDE,
                  F, LDF, SCALE, DIF, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void stgsyl_(const char *trans, const armpl_int_t *ijob, const armpl_int_t *m,
             const armpl_int_t *n, const float *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                const float *b, const armpl_int_t *ldb, float *c,
                const armpl_int_t *ldc, const float *d, const armpl_int_t *ldd,
                const float *e, const armpl_int_t *lde, float *f,
                const armpl_int_t *ldf, float *scale, float *dif, float *work,
                const armpl_int_t *lwork, armpl_int_t *iwork, armpl_int_t *info,
                ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N', solve the generalized Sylvester equation (1). = 'T', solve the 'transposed' system (3).

IJOB Input parameter.

IJOB is INTEGER

Specifies what kind of functionality to be performed. =0: solve (1) only. =1: The functionality of 0 and 3. =2: The functionality of 0 and 4. =3: Only an estimate of Dif[(A, D), (B, E)] is computed. (look ahead strategy IJOB = 1 is used). =4: Only an estimate of Dif[(A, D), (B, E)] is computed. (SGECON on sub-systems is used). Not referenced if TRANS = 'T'.

M Input parameter.

M is INTEGER

The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N Input parameter.

N is INTEGER

The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A Input parameter.

A is REAL

A is an array, dimension (LDA, M). The upper quasi triangular matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input parameter.

B is REAL

B is an array, dimension (LDB, N). The upper quasi triangular matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

C Input and output parameter.

C is REAL

C is an array, dimension (LDC, N). On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

D Input parameter.

D is REAL

D is an array, dimension (LDD, M). The upper triangular matrix D.

LDD Input parameter.

LDD is INTEGER

The leading dimension of the array D. LDD >= max(1, M).

E Input parameter.

E is REAL

E is an array, dimension (LDE, N). The upper triangular matrix E.

LDE Input parameter.

LDE is INTEGER

The leading dimension of the array E. LDE >= max(1, N).

F Input and output parameter.

F is REAL

F is an array, dimension (LDF, N). On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the array F. LDF >= max(1, M).

DIF Output parameter.

DIF is REAL

On exit DIF is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. DIF is an upper bound of Dif[(A, D), (B, E)] = sigma_min(Z), where Z as in (2). IF IJOB = 0 or TRANS = 'T', DIF is not touched.

SCALE Output parameter.

SCALE is REAL

On exit SCALE is the scaling factor in (1) or (3). If 0 < SCALE < 1, C and F hold the solutions R and L, resp., to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If SCALE = 0, C and F hold the solutions R and L, respectively, to the homogeneous system with C = F = 0. Normally, SCALE = 1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK > = 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= max(1,2*M*N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M+N+6)

INFO Output parameter.

INFO is INTEGER

=0: successful exit <0: If INFO = -i, the i-th argument had an illegal value. >0: (A, D) and (B, E) have common or close eigenvalues.

Related Information

For this routine in other precisions, please see *ctgsyl*, *dtgsyl* and *ztgsyl*. It also exists with a native C interface as *LAPACKE_stgsyl*.

4.14.49 zggbak

zggbak forms the right or left eigenvectors of a complex generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by ZGGBAL.

Syntax

Fortran specification:

```
use armpl_library

subroutine zggbak(JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V, LDV, INFO)
```

C specification:

```
#include "armpl.h"

void zggbak_(const char *job, const char *side, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             const double *lscale, const double *rscale, const armpl_int_t *m,
             armpl_doublecomplex_t *v, const armpl_int_t *ldv,
             armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the type of backward transformation required: = 'N': do nothing, return immediately; = 'P': do backward transformation for permutation only; = 'S': do backward transformation for scaling only; = 'B': do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to ZGGBAL.

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': V contains right eigenvectors; = 'L': V contains left eigenvectors.

N Input parameter.

N is INTEGER

The number of rows of the matrix V. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

The integers ILO and IHI determined by ZGGBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

LSCALE Input parameter.

LSCALE is DOUBLE PRECISION

LSCALE is an array, dimension (N). Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by ZGGBAL.

RSCALE Input parameter.

RSCALE is DOUBLE PRECISION

RSCALE is an array, dimension (N). Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by ZGGBAL.

M Input parameter.

M is INTEGER

The number of columns of the matrix V. M >= 0.

V Input and output parameter.

V is COMPLEX*16

V is an array, dimension (LDV, M). On entry, the matrix of right or left eigenvectors to be transformed, as returned by ZTGEVC. On exit, V is overwritten by the transformed eigenvectors.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the matrix V. LDV >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggbak*, *dggbak* and *sggbak*. It also exists with a native C interface as *LAPACKE_zggbak*.

4.14.50 zggbal

zggbal balances a pair of general complex matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem A*x = lambda*B*x.

Syntax

Fortran specification:

```
use armpl_library

subroutine zggbal(JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE, WORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zggbal_(const char *job, const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *ilo, armpl_int_t *ihi,
             double *lscale, double *rscale, double *work, armpl_int_t *info,
             ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies the operations to be performed on A and B: = 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i=1,...,N; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are set to integers such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE Output parameter.

LSCALE is DOUBLE PRECISION

LSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then LSCALE(j) = P(j) for J = 1,...,ILO-1 = D(j) for J = ILO,...,IHI = P(j) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE Output parameter.

RSCALE is DOUBLE PRECISION

RSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then RSCALE(j) = P(j) for J = 1,...,ILO-1 = D(j) for J = ILO,...,IHI = P(j) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (lwork). lwork must be at least max(1,6*N) when JOB = 'S' or 'B', and at least 1 when JOB = 'N' or 'P'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cggbal*, *dggbal* and *sggbal*. It also exists with a native C interface as *LAPACKE_zggbal*.

4.14.51 zgges

zgges computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )
```

where $(VSR)^H$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver ZGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgges(JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB, SDIM, ALPHA,
                 BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK, RWORK, BWORK,
                 INFO)
```

C specification:

```
#include "armpl.h"

void zgges_(const char *jobvsl, const char *jobvsr, const char *sort,
            ARMPL_ZGGES_DELCTG delctg, const armpl_int_t *n,
            armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *b, const armpl_int_t *ldb,
            armpl_int_t *sdim, armpl_doublecomplex_t *alpha,
            armpl_doublecomplex_t *beta, armpl_doublecomplex_t *vsl,
            const armpl_int_t *ldvsl, armpl_doublecomplex_t *vsr,
            const armpl_int_t *ldvsr, armpl_doublecomplex_t *work,
            const armpl_int_t *lwork, double *rwork, armpl_int_t *bwork,
            armpl_int_t *info, ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG).

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of two COMPLEX*16 arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue ALPHA(j)/BETA(j) is selected if SELCTG(ALPHA(j),BETA(j)) is true.

Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+2 (See INFO below).

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

ALPHA Output parameter.

ALPHA is COMPLEX*16

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX*16

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A, B) output by ZGGES. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is COMPLEX*16

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >= 1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is COMPLEX*16

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (8*N) .

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. =1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in ZHGEQZ =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in ZTGSEN.

Related Information

For this routine in other precisions, please see *cgges*, *dgges* and *sgges*. It also exists with a native C interface as *LAPACKE_zgges*.

4.14.52 zgges3

zgges3 computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )
```

where $(VSR)^H$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver ZGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgges3(JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB, SDIM,
                  ALPHA, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK, RWORK,
                  BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgges3_(const char *jobvsl, const char *jobvsr, const char *sort,
             ARMPL_ZGGES3_SELCTG selctg, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *sdim, armpl_doublecomplex_t *alpha,

```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG).

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of two COMPLEX*16 arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue ALPHA(j)/BETA(j) is selected if SELCTG(ALPHA(j),BETA(j)) is true.

Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+2 (See INFO below).

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

ALPHA Output parameter.

ALPHA is COMPLEX*16

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX*16

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A, B) output by ZGGES3. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is COMPLEX*16

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >= 1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is COMPLEX*16

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (8*N) .

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. =1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in ZHGEQZ =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in ZTGSEN.

Related Information

For this routine in other precisions, please see *cgges3*, *dgges3* and *sgges3*. It also exists with a native C interface as *LAPACKE_zgges3*.

4.14.53 zggesx

zggesx computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL) S (VSR)**H, (VSL) T (VSR)**H )
```

where $(VSR)^H$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if T is upper triangular with non-negative diagonal and S is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine zggesx(JOBVSL, JOBVSR, SORT, SELCTG, SENSE, N, A, LDA, B, LDB,
                  SDIM, ALPHA, BETA, VSL, LDVSL, VSR, LDVSR, RCONDE, RCONDV,
                  WORK, LWORK, RWORK, IWORK, LIWORK, BWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zggesx_(const char *jobvsl, const char *jobvsr, const char *sort,
             ARMPL_ZGGESX_DELCTG delctg, const char *sense,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_int_t *sdim,
             armpl_doublecomplex_t *alpha, armpl_doublecomplex_t *beta,
             armpl_doublecomplex_t *vsl, const armpl_int_t *ldvsl,
             armpl_doublecomplex_t *vsr, const armpl_int_t *ldvsr,
             double *rconde, double *rcondv, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *bwork, armpl_int_t *info,
             ... );
```

Parameters

JOBVSL Input parameter.

JOBVSL is CHARACTER*1

= 'N': do not compute the left Schur vectors; = 'V': compute the left Schur vectors.

JOBVSR Input parameter.

JOBVSR is CHARACTER*1

= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.

SORT Input parameter.

SORT is CHARACTER*1

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see SELCTG).

SELCTG Input parameter.

SELCTG is a LOGICAL FUNCTION of two COMPLEX*16 arguments

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3 see INFO below).

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N' : None are computed; = 'E' : Computed for average of selected eigenvalues only; = 'V' : Computed for selected deflating subspaces only; = 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VSL, and VSR. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

SDIM Output parameter.

SDIM is INTEGER

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

ALPHA Output parameter.

ALPHA is COMPLEX*16

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX*16

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues. ALPHA(j) and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T). BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VSL Output parameter.

VSL is COMPLEX*16

VSL is an array, dimension (LDVSL, N). If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL Input parameter.

LDVSL is INTEGER

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR Output parameter.

VSR is COMPLEX*16

VSR is an array, dimension (LDVSR, N). If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR Input parameter.

LDVSR is INTEGER

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

RCONDE Output parameter.

RCONDE is DOUBLE PRECISION

RCONDE is an array, dimension (2). If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV Output parameter.

RCONDV is DOUBLE PRECISION

RCONDV is an array, dimension (2). If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition number for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N = 0, LWORK >= 1, else if SENSE = 'E', 'V', or 'B', LWORK >= MAX(1,2*N,2*SDIM*(N-SDIM)), else LWORK >= MAX(1,2*N). Note that 2*SDIM*(N-SDIM) <= N*N/2. Note also that an error is only returned if LWORK < MAX(1,2*N), but if SENSE = 'E' or 'V' or 'B' this may not be large enough.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the WORK array and the minimum size of the IWORK array, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (8* N). Real workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If SENSE = 'N' or N = 0, LIWORK >= 1, otherwise LIWORK >= N+2.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the WORK array and the minimum size of the IWORK array, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). Not referenced if SORT = 'N'.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. (A, B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in ZHGEQZ =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in ZTGSEN.

4.14.54 zggev

zggev computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right generalized eigenvector v(j) corresponding to the generalized eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j).
```

The left generalized eigenvector u(j) corresponding to the generalized eigenvalues lambda(j) of (A,B) satisfies

```
u(j)**H * A = lambda(j) * u(j)**H * B
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine zggev(JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHA, BETA, VL, LDVL, VR,
                 LDVR, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zggev_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
            armpl_doublecomplex_t *a, const armpl_int_t *lda,
            armpl_doublecomplex_t *b, const armpl_int_t *ldb,
            armpl_doublecomplex_t *alpha, armpl_doublecomplex_t *beta,

            armpl_doublecomplex_t *work, const armpl_int_t *lwork,
            double *rwork, armpl_int_t *info, ... );
```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX*16

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX*16

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left generalized eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right generalized eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (8*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. =1,. . . ,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,. . . ,N. > N: =N+1: other then QZ iteration failed in DHGEQZ, =N+2: error return from DTGEVC.

Related Information

For this routine in other precisions, please see *cggev*, *dggev* and *sggev*. It also exists with a native C interface as *LAPACKE_zggev*.

4.14.55 zggev3

zggev3 computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right generalized eigenvector v(j) corresponding to the generalized eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j).
```

The left generalized eigenvector u(j) corresponding to the generalized eigenvalues lambda(j) of (A,B) satisfies

```
u(j)**H * A = lambda(j) * u(j)**H * B
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine zggev3(JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHA, BETA, VL, LDVL, VR,
                  LDVR, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zggev3_(const char *jobvl, const char *jobvr, const armpl_int_t *n,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,

```

Parameters

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX*16

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX*16

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left generalized eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right generalized eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (8*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. =1,. . . ,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,. . . ,N. > N: =N+1: other then QZ iteration failed in DHGEQZ, =N+2: error return from DTGEVC.

Related Information

For this routine in other precisions, please see *cggev3*, *dggev3* and *sggev3*. It also exists with a native C interface as *LAPACKE_zggev3*.

4.14.56 zggevx

zggevx computes for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally, it also computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j) .
```

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
u(j)**H * A  = lambda(j) * u(j)**H * B.
```

where $u(j)^H$ is the conjugate-transpose of u(j).

Syntax

Fortran specification:

```
use armpl_library

subroutine zggevx(BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, B, LDB, ALPHA, BETA,

```

Parameters

BALANC Input parameter.

BALANC is CHARACTER*1

Specifies the balance option to be performed: = 'N': do not diagonally scale or permute; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL Input parameter.

JOBVL is CHARACTER*1

= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.

JOBVR Input parameter.

JOBVR is CHARACTER*1

= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.

SENSE Input parameter.

SENSE is CHARACTER*1

Determines which reciprocal condition numbers are computed. = 'N': none are computed; = 'E': computed for eigenvalues only; = 'V': computed for eigenvectors only; = 'B': computed for eigenvalues and eigenvectors.

N Input parameter.

N is INTEGER

The order of the matrices A, B, VL, and VR. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the matrix A in the pair (A, B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the complex Schur form of the "balanced" versions of the input A and B.

LDA Input parameter.

LDA is INTEGER

The leading dimension of A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the matrix B in the pair (A, B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the complex Schur form of the "balanced" versions of the input A and B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX*16

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX*16

BETA is an array, dimension (N). On exit, ALPHA(j)/BETA(j), j=1,..., N, will be the generalized eigenvalues.

Note: the quotient ALPHA(j)/BETA(j)) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

VL Output parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, N). If JOBVL = 'V', the left generalized eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR Output parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, N). If JOBVR = 'V', the right generalized eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO Output parameter.

ILO is INTEGER

IHI Output parameter.

IHI is INTEGER

ILO and IHI are integer values such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE Output parameter.

LSCALE is DOUBLE PRECISION

LSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to

row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1 = DL(j) for j = ILO,...,IHI = PL(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE Output parameter.

RSCALE is DOUBLE PRECISION

RSCALE is an array, dimension (N). Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1 = DR(j) for j = ILO,...,IHI = PR(j) for j = IHI+1,...,N The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM Output parameter.

ABNRM is DOUBLE PRECISION

The one-norm of the balanced matrix A.

BBNRM Output parameter.

BBNRM is DOUBLE PRECISION

The one-norm of the balanced matrix B.

RCONDE Output parameter.

RCONDE is DOUBLE PRECISION

RCONDE is an array, dimension (N). If SENSE = 'E' or 'B', the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. If SENSE = 'N' or 'V', RCONDE is not referenced.

RCONDV Output parameter.

RCONDV is DOUBLE PRECISION

RCONDV is an array, dimension (N). If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'N' or 'E', RCONDV is not referenced.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1,2*N). If SENSE = 'E', LWORK >= max(1,4*N). If SENSE = 'V' or 'B', LWORK >= max(1,2*N*N+2*N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (lrwork). lrwork must be at least max(1,6*N) if BALANC = 'S' or 'B', and at least max(1,2*N) otherwise. Real workspace.

IWORK Output parameter.

IWORK is INTEGER array, dimension (N+2)

If SENSE = 'E', IWORK is not referenced.

BWORK Output parameter.

BWORK is LOGICAL

BWORK is an array, dimension (N). If SENSE = 'N', BWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. = 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in ZHGEQZ. =N+2: error return from ZTGEVC.

4.14.57 zgghd3

zgghd3 reduces a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is

```
A*x = lambda*B*x,
```

and B is typically made upper triangular by computing its QR factorization and moving the unitary matrix Q to the left side of the equation.

This subroutine simultaneously reduces A to a Hessenberg matrix H:

```
Q**H*A*Z = H
```

and transforms B to another upper triangular matrix T:

```
Q**H*B*Z = T
```

in order to reduce the problem to its standard form

```
H*y = lambda*T*y
```

where y = Z^H *x.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

```
 Q1 * A * Z1**H = (Q1*Q) * H * (Z1*Z)**H
Q1 * B * Z1**H = (Q1*Q) * T * (Z1*Z)**H
```

If Q1 is the unitary matrix from the QR factorization of B in the original equation A*x = lambda*B*x, then zgghd3 reduces the original problem to generalized Hessenberg form.

This is a blocked variant of CGGHRD, using matrix-matrix multiplications for parts of the computation to enhance performance.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgghd3(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgghd3_(const char *compq, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *q, const armpl_int_t *ldq,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'N': do not compute Q; = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': do not compute Z; = 'I': Z is initialized to the unit matrix, and the unitary matrix Z is returned; = 'V': Z must contain a unitary matrix Z1 on entry, and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to ZGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q^H B Z. The elements below the diagonal are set to zero.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the unitary matrix Q1, typically from the QR factorization of B. On exit, if COMPQ='I', the unitary matrix Q, and if COMPQ = 'V', the product Q1*Q. Not referenced if COMPQ='N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the unitary matrix Z1. On exit, if COMPZ='I', the unitary matrix Z, and if COMPZ = 'V', the product Z1*Z. Not referenced if COMPZ='N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1. For optimum performance LWORK >= 6*N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgghd3*, *dgghd3* and *sgghd3*. It also exists with a native C interface as *LAPACKE_zgghd3*.

4.14.58 zgghrd

`zgghrd` reduces a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is

```
A*x = lambda*B*x,
```

and B is typically made upper triangular by computing its QR factorization and moving the unitary matrix Q to the left side of the equation.

This subroutine simultaneously reduces A to a Hessenberg matrix H:

```
Q**H*A*Z = H
```

and transforms B to another upper triangular matrix T:

```
Q**H*B*Z = T
```

in order to reduce the problem to its standard form

```
H*y = lambda*T*y
```

where y = Z^H *x.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

```
 Q1 * A * Z1**H = (Q1*Q) * H * (Z1*Z)**H
Q1 * B * Z1**H = (Q1*Q) * T * (Z1*Z)**H
```

If Q1 is the unitary matrix from the QR factorization of B in the original equation A*x = lambda*B*x, then `zgghrd` reduces the original problem to generalized Hessenberg form.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgghrd(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zgghrd_(const char *compq, const char *compz, const armpl_int_t *n,
             const armpl_int_t *ilo, const armpl_int_t *ihi,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_doublecomplex_t *q, const armpl_int_t *ldq,
             armpl_doublecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *info, ... );
```

Parameters

COMPQ Input parameter.

`COMPQ` is `CHARACTER*1`

= 'N': do not compute Q; = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': do not compute Z; = 'I': Z is initialized to the unit matrix, and the unitary matrix Z is returned; = 'V': Z must contain a unitary matrix Z1 on entry, and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to ZGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q^H B Z. The elements below the diagonal are set to zero.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the unitary matrix Q1, typically from the QR factorization of B. On exit, if COMPQ='I', the unitary matrix Q, and if COMPQ = 'V', the product Q1*Q. Not referenced if COMPQ='N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the unitary matrix Z1. On exit, if COMPZ='I', the unitary matrix Z, and if COMPZ = 'V', the product Z1*Z. Not referenced if COMPZ='N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *cgghrd*, *dgghrd* and *sgghrd*. It also exists with a native C interface as *LAPACKE_zgghrd*.

4.14.59 zhgeqz

zhgeqz computes the eigenvalues of a complex matrix pair (H,T), where H is an upper Hessenberg matrix and T is upper triangular, using the single-shift QZ method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a complex matrix pair (A,B):

```
A = Q1*H*Z1**H,  B = Q1*T*Z1**H,
```

as computed by ZGGHRD.

If JOB='S', then the Hessenberg-triangular pair (H,T) is also reduced to generalized Schur form,

```
H = Q*S*Z**H,  T = Q*P*Z**H,
```

where Q and Z are unitary matrices and S and P are upper triangular.

Optionally, the unitary matrix Q from the generalized Schur factorization may be postmultiplied into an input matrix Q1, and the unitary matrix Z may be postmultiplied into an input matrix Z1. If Q1 and Z1 are the unitary matrices from ZGGHRD that reduced the matrix pair (A,B) to generalized Hessenberg form, then the output matrices Q1*Q and Z1*Z are the unitary factors from the generalized Schur factorization of (A,B):

```
A = (Q1*Q)*S*(Z1*Z)**H,  B = (Q1*Q)*P*(Z1*Z)**H.
```

To avoid overflow, eigenvalues of the matrix pair (H,T) (equivalently, of (A,B)) are computed as a pair of complex values (alpha,beta). If beta is nonzero, lambda = alpha / beta is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

```
A*x = lambda*B*x
```

and if alpha is nonzero, mu = beta / alpha is an eigenvalue of the alternate form of the GNEP

```
mu*A*y = B*y.
```

The values of alpha and beta for the i-th eigenvalue can be read directly from the generalized Schur form: alpha = S(i,i), beta = P(i,i).

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrix Eigenvalue Problems", SIAM J. Numer. Anal., 10(1973), pp. 241–256.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhgeqz(JOB, COMPQ, COMPZ, N, ILO, IHI, H, LDH, T, LDT, ALPHA, BETA,
                  Q, LDQ, Z, LDZ, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhgeqz_(const char *job, const char *compq, const char *compz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_doublecomplex_t *h,
             const armpl_int_t *ldh, armpl_doublecomplex_t *t,
             const armpl_int_t *ldt, armpl_doublecomplex_t *alpha,
             armpl_doublecomplex_t *beta, armpl_doublecomplex_t *q,
             const armpl_int_t *ldq, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

= 'E': Compute eigenvalues only; = 'S': Computer eigenvalues and the Schur form.

COMPQ Input parameter.

COMPQ is CHARACTER*1

= 'N': Left Schur vectors (Q) are not computed; = 'I': Q is initialized to the unit matrix and the matrix Q of left Schur vectors of (H, T) is returned; = 'V': Q must contain a unitary matrix Q1 on entry and the product Q1* Q is returned.

COMPZ Input parameter.

COMPZ is CHARACTER*1

= 'N': Right Schur vectors (Z) are not computed; = 'I': Q is initialized to the unit matrix and the matrix Z of right Schur vectors of (H, T) is returned; = 'V': Z must contain a unitary matrix Z1 on entry and the product Z1* Z is returned.

N Input parameter.

N is INTEGER

The order of the matrices H, T, Q, and Z. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

ILO and IHI mark the rows and columns of H which are in Hessenberg form. It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. If N > 0, 1 <= ILO <= IHI <= N; if N = 0, ILO=1 and IHI=0.

H Input and output parameter.

H is COMPLEX*16

H is an array, dimension (LDH, N). On entry, the N-by-N upper Hessenberg matrix H. On exit, if JOB = 'S', H contains the upper triangular matrix S from the generalized Schur factorization. If JOB = 'E', the diagonal of H matches that of S, but the rest of H is unspecified.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

T Input and output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). On entry, the N-by-N upper triangular matrix T. On exit, if JOB = 'S', T contains the upper triangular matrix P from the generalized Schur factorization. If JOB = 'E', the diagonal of T matches that of P, but the rest of T is unspecified.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX*16

ALPHA is an array, dimension (N). The complex scalars alpha that define the eigenvalues of GNEP. ALPHA(i) = S(i,i) in the generalized Schur factorization.

BETA Output parameter.

BETA is COMPLEX*16

BETA is an array, dimension (N). The real non-negative scalars beta that define the eigenvalues of GNEP. BETA(i) = P(i,i) in the generalized Schur factorization.

Together, the quantities alpha = ALPHA(j) and beta = BETA(j) represent the j-th eigenvalue of the matrix pair (A,B), in one of the forms lambda = alpha/beta or mu = beta/alpha. Since either lambda or mu may overflow, they should not, in general, be computed.

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, if COMPQ = 'V', the unitary matrix Q1 used in the reduction of (A,B) to generalized Hessenberg form. On exit, if COMPQ = 'I', the unitary matrix of left Schur vectors of (H, T), and if COMPQ = 'V', the unitary matrix of left Schur vectors of (A,B). Not referenced if COMPQ = 'N'.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If COMPQ='V' or 'I', then LDQ >= N.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). On entry, if COMPZ = 'V', the unitary matrix Z1 used in the reduction of (A,B) to generalized Hessenberg form. On exit, if COMPZ = 'I', the unitary matrix of right Schur vectors of (H, T), and if COMPZ = 'V', the unitary matrix of right Schur vectors of (A,B). Not referenced if COMPZ = 'N'.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If COMPZ='V' or 'I', then LDZ >= N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value = 1,...,N: the QZ iteration did not converge. (H, T) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (H, T) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO-N+1,...,N should be correct.

Related Information

4.14.60 ztgevc

ztgevc computes some or all of the right and/or left eigenvectors of a pair of complex matrices (S,P), where S and P are upper triangular. Matrix pairs of this type are produced by the generalized Schur factorization of a complex matrix pair (A,B):

```
A = Q*S*Z**H,  B = Q*P*Z**H
```

as computed by ZGGHRD + ZHGEQZ.

The right eigenvector x and the left eigenvector y of (S,P) corresponding to an eigenvalue w are defined by:

```
S*x = w*P*x,  (y**H)*S = w*(y**H)*P,
```

where y^H denotes the conjugate tranpose of y. The eigenvalues are not input to this routine, but are computed directly from the diagonal elements of S and P.

This routine returns the matrices X and/or Y of right and left eigenvectors of (S,P), or the products Z*X and/or Q*Y, where Z and Q are input matrices. If Q and Z are the unitary factors from the generalized Schur factorization of a matrix pair (A,B), then Z*X and Q*Y are the matrices of right and left eigenvectors of (A,B).

Syntax

Fortran specification:

```
use armpl_library

subroutine ztgevc(SIDE, HOWMNY, SELECT, N, S, LDS, P, LDP, VL, LDVL, VR, LDVR,
                  MM, M, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztgevc_(const char *side, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const armpl_doublecomplex_t *s,
             const armpl_int_t *lds, const armpl_doublecomplex_t *p,
             const armpl_int_t *ldp, armpl_doublecomplex_t *vl,
             const armpl_int_t *ldvl, armpl_doublecomplex_t *vr,
             const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed by the matrices in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY='S', SELECT specifies the eigenvectors to be computed. The eigenvector corresponding to the j-th eigenvalue is computed if SELECT(j) = .TRUE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrices S and P. N >= 0.

S Input parameter.

S is COMPLEX*16

S is an array, dimension (LDS, N). The upper triangular matrix S from a generalized Schur factorization, as computed by ZHGEQZ.

LDS Input parameter.

LDS is INTEGER

The leading dimension of array S. LDS >= max(1, N).

P Input parameter.

P is COMPLEX*16

P is an array, dimension (LDP, N). The upper triangular matrix P from a generalized Schur factorization, as computed by ZHGEQZ. P must have real diagonal elements.

LDP Input parameter.

LDP is INTEGER

The leading dimension of array P. LDP >= max(1, N).

VL Input and output parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of left Schur vectors returned by ZHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (S, P); if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of (S, P) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of array VL. LDVL >= 1, and if SIDE = 'L' or 'l' or 'B' or 'b', LDVL >= N.

VR Input and output parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Z of right Schur vectors returned by ZHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (S, P); if HOWMNY = 'B', the matrix Z*X; if HOWMNY = 'S', the right eigenvectors of (S, P) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *ctgevc*, *dtgevc* and *stgevc*. It also exists with a native C interface as *LAPACKE_ztgevc*.

4.14.61 ztgexc

ztgexc reorders the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation (A, B) := Q * (A, B) * Z^H , so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
 Q(in) * A(in) * Z(in)**H = Q(out) * A(out) * Z(out)**H
Q(in) * B(in) * Z(in)**H = Q(out) * B(out) * Z(out)**H
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ztgexc(WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, IFST, ILST,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ztgexc_(const armpl_int_t *wantq, const armpl_int_t *wantz,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *q,
             const armpl_int_t *ldq, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, const armpl_int_t *ifst,
             armpl_int_t *ilst, armpl_int_t *info);
```

Parameters

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the upper triangular matrix A in the pair (A, B). On exit, the updated matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the upper triangular matrix B in the pair (A, B). On exit, the updated matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., the unitary matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1; If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). On entry, if WANTZ = .TRUE., the unitary matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

IFST Input parameter.

IFST is INTEGER

ILST Input and output parameter.

ILST is INTEGER

Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks.

INFO Output parameter.

INFO is INTEGER

=0: Successful exit. <0: if INFO = -i, the i-th argument had an illegal value. =1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill- conditioned. (A, B) may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

Related Information

For this routine in other precisions, please see *ctgexc*, *dtgexc* and *stgexc*. It also exists with a native C interface as *LAPACKE_ztgexc*.

4.14.62 ztgsen

ztgsen reorders the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence trans- formation Q^H * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B). The leading columns of Q and Z form unitary bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ztgsen also computes the generalized eigenvalues

```
w(j)= ALPHA(j) / BETA(j)
```

of the reordered matrix pair (A, B).

Optionally, the routine computes estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztgsen(IJOB, WANTQ, WANTZ, SELECT, N, A, LDA, B, LDB, ALPHA, BETA,
                  Q, LDQ, Z, LDZ, M, PL, PR, DIF, WORK, LWORK, IWORK, LIWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ztgsen_(const armpl_int_t *ijob, const armpl_int_t *wantq,
             const armpl_int_t *wantz, const armpl_int_t *select,
             const armpl_int_t *n, armpl_doublecomplex_t *a,
             const armpl_int_t *lda, armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *alpha,
             armpl_doublecomplex_t *beta, armpl_doublecomplex_t *q,
             const armpl_int_t *ldq, armpl_doublecomplex_t *z,
             const armpl_int_t *ldz, armpl_int_t *m, double *pl, double *pr,
             double *dif, armpl_doublecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *iwork,
             const armpl_int_t *liwork, armpl_int_t *info);
```

Parameters

IJOB Input parameter.

IJOB is INTEGER

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl): =0: Only reorder w.r.t. SELECT. No extras. =1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate (DIF(1:2)). =3: Estimate of Difu and Difl. 1-norm-based estimate (DIF(1:2)). About 5 times as expensive as IJOB = 2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ Input parameter.

WANTQ is LOGICAL

.TRUE. : update the left transformation matrix Q; .FALSE.: do not update Q.

WANTZ Input parameter.

WANTZ is LOGICAL

.TRUE. : update the right transformation matrix Z; .FALSE.: do not update Z.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). SELECT specifies the eigenvalues in the selected cluster. To select an eigenvalue w(j), SELECT(j) must be set to .TRUE..

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension(LDA, N). On entry, the upper triangular matrix A, in generalized Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension(LDB, N). On entry, the upper triangular matrix B, in generalized Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

ALPHA Output parameter.

ALPHA is COMPLEX*16

ALPHA is an array, dimension (N) .

BETA Output parameter.

BETA is COMPLEX*16

BETA is an array, dimension (N). The diagonal elements of A and B, respectively, when the pair (A, B) has been reduced to generalized Schur form. ALPHA(i)/BETA(i) i=1,...,N are the generalized eigenvalues.

Q Input and output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= 1. If WANTQ = .TRUE., LDQ >= N.

Z Input and output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

M Output parameter.

M is INTEGER

The dimension of the specified pair of left and right eigenspaces, (deflating subspaces) 0 <= M <= N.

PL Output parameter.

PL is DOUBLE PRECISION

PR Output parameter.

PR is DOUBLE PRECISION

If IJOB = 1, 4 or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspace with respect to the selected cluster. 0 < PL, PR <= 1. If M = 0 or M = N, PL = PR = 1. If IJOB = 0, 2 or 3 PL, PR are not referenced.

DIF Output parameter.

DIF is DOUBLE PRECISION

DIF is an array, dimension (2).. If IJOB >= 2, DIF(1:2) store the estimates of Difu and Difl. If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl, computed using reversed communication with ZLACN2. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= 1 If IJOB = 1, 2 or 4, LWORK >= 2*M*(N-M) If IJOB = 3 or 5, LWORK >= 4*M*(N-M)

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= 1. If IJOB = 1, 2 or 4, LIWORK >= N+2; If IJOB = 3 or 5, LIWORK >= MAX(N+2, 2*M*(N-M));

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

=0: Successful exit. <0: If INFO = -i, the i-th argument had an illegal value. =1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

Related Information

For this routine in other precisions, please see *ctgsen*, *dtgsen* and *stgsen*. It also exists with a native C interface as *LAPACKE_ztgsen*.

4.14.63 ztgsna

ztgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B).

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztgsna(JOB, HOWMNY, SELECT, N, A, LDA, B, LDB, VL, LDVL, VR, LDVR,
                  S, DIF, MM, M, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztgsna_(const char *job, const char *howmny, const armpl_int_t *select,
             const armpl_int_t *n, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, const armpl_doublecomplex_t *vl,
             const armpl_int_t *ldvl, const armpl_doublecomplex_t *vr,
             const armpl_int_t *ldvr, double *s, double *dif,
             const armpl_int_t *mm, armpl_int_t *m,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

JOB Input parameter.

JOB is CHARACTER*1

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF): = 'E': for eigenvalues only (S); = 'V': for eigenvectors only (DIF); = 'B': for both eigenvalues and eigenvectors (S and DIF).

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute condition numbers for all eigenpairs; = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the corresponding j-th eigenvalue and/or eigenvector, SELECT(j) must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N Input parameter.

N is INTEGER

The order of the square matrix pair (A, B). N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The upper triangular matrix A in the pair (A, B).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). The upper triangular matrix B in the pair (A, B).

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

VL Input parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, M). IF JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by ZTGEVC. If JOB = 'V', VL is not referenced.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1; and If JOB = 'E' or 'B', LDVL >= N.

VR Input parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, M). IF JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by ZTGEVC. If JOB = 'V', VR is not referenced.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1; If JOB = 'E' or 'B', LDVR >= N.

S Output parameter.

S is DOUBLE PRECISION

S is an array, dimension (MM). If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If JOB = 'V', S is not referenced.

DIF Output parameter.

DIF is DOUBLE PRECISION

DIF is an array, dimension (MM). If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. For each eigenvalue/vector specified by SELECT, DIF stores a Frobenius norm-based estimate of Difl. If JOB = 'E', DIF is not referenced.

MM Input parameter.

MM is INTEGER

The number of elements in the arrays S and DIF. MM >= M.

M Output parameter.

M is INTEGER

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected eigenvalue one element is used. If HOWMNY = 'A', M is set to N.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK >= max(1, N). If JOB = 'V' or 'B', LWORK >= max(1,2*N*N).

IWORK Output parameter.

IWORK is INTEGER array, dimension (N+2)

If JOB = 'E', IWORK is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit < 0: If INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctgsna*, *dtgsna* and *stgsna*. It also exists with a native C interface as *LAPACKE_ztgsna*.

4.14.64 ztgsyl

`ztgsyl` solves the generalized Sylvester equation:

```
 A * R - L * B = scale * C            (1)
D * R - L * E = scale * F
```

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with complex entries. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve Zx = scale*b, where Z is defined as

```
Z = [ kron(In, A)  -kron(B**H, Im) ]         (2)
    [ kron(In, D)  -kron(E**H, Im) ],
```

Here Ix is the identity matrix of size x and X^H is the conjugate transpose of X. Kron(X, Y) is the Kronecker product between the matrices X and Y.

If TRANS = 'C', y in the conjugate transposed system Z^H *y = scale*b is solved for, which is equivalent to solve for R and L in

```
 A**H * R + D**H * L = scale * C            (3)
R * B**H + L * E**H = scale * -F
```

This case (TRANS = 'C') is used to compute an one-norm-based estimate of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D) and (B,E), using ZLACON.

If IJOB >= 1, `ztgsyl` computes a Frobenius norm-based estimate of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z.

This is a level-3 BLAS algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztgsyl(TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD, E, LDE,
                  F, LDF, SCALE, DIF, WORK, LWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztgsyl_(const char *trans, const armpl_int_t *ijob, const armpl_int_t *m,
             const armpl_int_t *n, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, const armpl_doublecomplex_t *b,
             const armpl_int_t *ldb, armpl_doublecomplex_t *c,
             const armpl_int_t *ldc, const armpl_doublecomplex_t *d,
             const armpl_int_t *ldd, const armpl_doublecomplex_t *e,
             const armpl_int_t *lde, armpl_doublecomplex_t *f,
             const armpl_int_t *ldf, double *scale, double *dif,
             armpl_doublecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': solve the generalized sylvester equation (1). = 'C': solve the "conjugate transposed" system (3).

IJOB Input parameter.

IJOB is INTEGER

Specifies what kind of functionality to be performed. =0: solve (1) only. =1: The functionality of 0 and 3. =2: The functionality of 0 and 4. =3: Only an estimate of Dif[(A, D), (B, E)] is computed. (look ahead strategy is used). =4: Only an estimate of Dif[(A, D), (B, E)] is computed. (ZGECON on sub-systems is used). Not referenced if TRANS = 'C'.

M Input parameter.

M is INTEGER

The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N Input parameter.

N is INTEGER

The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, M). The upper triangular matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). The upper triangular matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

C Input and output parameter.

C is COMPLEX*16

C is an array, dimension (LDC, N). On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

D Input parameter.

D is COMPLEX*16

D is an array, dimension (LDD, M). The upper triangular matrix D.

LDD Input parameter.

LDD is INTEGER

The leading dimension of the array D. LDD >= max(1, M).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (LDE, N). The upper triangular matrix E.

LDE Input parameter.

LDE is INTEGER

The leading dimension of the array E. LDE >= max(1, N).

F Input and output parameter.

F is COMPLEX*16

F is an array, dimension (LDF, N). On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the array F. LDF >= max(1, M).

DIF Output parameter.

DIF is DOUBLE PRECISION

On exit DIF is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. DIF is an upper bound of Dif[(A, D), (B, E)] = sigma-min(Z), where Z as in (2). IF IJOB = 0 or TRANS = 'C', DIF is not referenced.

SCALE Output parameter.

SCALE is DOUBLE PRECISION

On exit SCALE is the scaling factor in (1) or (3). If 0 < SCALE < 1, C and F hold the solutions R and L, resp., to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If SCALE = 0, R and L will hold the solutions to the homogenious system with C = F = 0.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK > = 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= max(1,2*M*N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (M+N+2)

INFO Output parameter.

INFO is INTEGER

=0: successful exit <0: If INFO = -i, the i-th argument had an illegal value. >0: (A, D) and (B, E) have common or very close eigenvalues.

4.15 LAPACK condition number estimation routines

4.15.1 cgbcon

`cgbcon` estimates the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbcon(NORM, N, KL, KU, AB, LDAB, IPIV, ANORM, RCOND, WORK, RWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void cgbcon_(const char *norm, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_singlecomplex_t *ab,
             const armpl_int_t *ldab, const armpl_int_t *ipiv,
             const float *anorm, float *rcond, armpl_singlecomplex_t *work,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = ‘1’ or ‘O’: 1-norm; = ‘I’: Infinity-norm.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

KL Input parameter.

`KL` is `INTEGER`

The number of subdiagonals within the band of A. `KL` >= 0.

KU Input parameter.

`KU` is `INTEGER`

The number of superdiagonals within the band of A. `KU` >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIV(i).

ANORM Input parameter.

ANORM is REAL

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgbcon*, *sgbcon* and *zgbcon*. It also exists with a native C interface as *LAPACKE_cgbcon*.

4.15.2 cgecon

cgecon estimates the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cgecon(NORM, N, A, LDA, ANORM, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgecon_(const char *norm, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const float *anorm, float *rcond, armpl_singlecomplex_t *work,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ANORM Input parameter.

ANORM is REAL

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgecon*, *sgecon* and *zgecon*. It also exists with a native C interface as *LAPACKE_cgecon*.

4.15.3 cgtcon

cgtcon estimates the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine cgtcon(NORM, N, DL, D, DU, DU2, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgtcon_(const char *norm, const armpl_int_t *n,
             const armpl_singlecomplex_t *dl, const armpl_singlecomplex_t *d,
             const armpl_singlecomplex_t *du,
             const armpl_singlecomplex_t *du2, const armpl_int_t *ipiv,
             const float *anorm, float *rcond, armpl_singlecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

DL Input parameter.

DL is COMPLEX

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

D Input parameter.

D is COMPLEX

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is COMPLEX

DU is an array, dimension (N-1). The (n-1) elements of the first superdiagonal of U.

DU2 Input parameter.

DU2 is COMPLEX

DU2 is an array, dimension (N-2). The (n-2) elements of the second superdiagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

ANORM Input parameter.

ANORM is REAL

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgtcon*, *sgtcon* and *zgtcon*. It also exists with a native C interface as *LAPACKE_cgtcon*.

4.15.4 checon

checon estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by CHETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine checon(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void checon_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, const float *anorm, float *rcond,
             armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhecon*. It also exists with a native C interface as *LAPACKE_checon*.

4.15.5 checon_3

CHECON_3 estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian matrix A using the factorization computed by CHETRF_RK or CHETRF_BK:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))). This routine uses BLAS3 solver CHETRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine checon_3(UPLO, N, A, LDA, E, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void checon_3_(const char *uplo, const armpl_int_t *n,
               const armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_singlecomplex_t *e, const armpl_int_t *ipiv,
               const float *anorm, float *rcond, armpl_singlecomplex_t *work,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^H)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^H)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by CHETRF_RK and CHETRF_BK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D

on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF_RK or CHETRF_BK.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhecon_3*. It also exists with a native C interface as *LAPACKE_checon_3*.

4.15.6 checon_rook

CHECON_ROOK estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by CHETRF_ROOK.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine checon_rook(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void checon_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  const armpl_int_t *ipiv, const float *anorm, float *rcond,
                  armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF_ROOK.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhecon_rook*.

4.15.7 chpcon

chpcon estimates the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by CHPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine chpcon(UPLO, N, AP, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void chpcon_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *ap, const armpl_int_t *ipiv,
             const float *anorm, float *rcond, armpl_singlecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHPTRF.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhpcon*. It also exists with a native C interface as *LAPACKE_chpcon*.

4.15.8 cpbcon

cpbcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization A = U^H *U or A = L*L^H computed by CPBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine cpbcon(UPLO, N, KD, AB, LDAB, ANORM, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cpbcon_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             const float *anorm, float *rcond, armpl_singlecomplex_t *work,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor stored in AB; = 'L': Lower triangular factor stored in AB.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array AB as follows: if UPLO ='U', AB(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', AB(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

ANORM Input parameter.

ANORM is REAL

The 1-norm (or infinity-norm) of the Hermitian band matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dpbcon*, *spbcon* and *zpbcon*. It also exists with a native C interface as *LAPACKE_cpbcon*.

4.15.9 cpocon

cpocon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization A = U^H *U or A = L*L^H computed by CPOTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine cpocon(UPLO, N, A, LDA, ANORM, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cpocon_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const float *anorm, float *rcond, armpl_singlecomplex_t *work,
             float *rwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by CPOTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ANORM Input parameter.

ANORM is REAL

The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dpocon*, *spocon* and *zpocon*. It also exists with a native C interface as *LAPACKE_cpocon*.

4.15.10 cppcon

cppcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization A = U^H *U or A = L*L^H computed by CPPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine cppcon(UPLO, N, AP, ANORM, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cppcon_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *ap, const float *anorm,
             float *rcond, armpl_singlecomplex_t *work, float *rwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , packed columnwise in a linear array. The j-th column of U or L is stored in the array AP as

follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

ANORM Input parameter.

ANORM is REAL

The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dppcon*, *sppcon* and *zppcon*. It also exists with a native C interface as *LAPACKE_cppcon*.

4.15.11 cptcon

cptcon computes the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization A = L*D*L^H or A = U^H *D*U computed by CPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

```
RCOND = 1 / (ANORM * norm(inv(A))).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cptcon(N, D, E, ANORM, RCOND, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cptcon_(const armpl_int_t *n, const float *d,
             const armpl_singlecomplex_t *e, const float *anorm, float *rcond,
             float *rwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization of A, as computed by CPTTRF.

E Input parameter.

E is COMPLEX

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by CPTTRF.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the 1-norm of inv(A) computed in this routine.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dptcon*, *sptcon* and *zptcon*. It also exists with a native C interface as *LAPACKE_cptcon*.

4.15.12 cspcon

cspcon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine cspcon(UPLO, N, AP, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cspcon_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *ap, const armpl_int_t *ipiv,
             const float *anorm, float *rcond, armpl_singlecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSPTRF.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dspcon*, *sspcon* and *zspcon*. It also exists with a native C interface as *LAPACKE_cspcon*.

4.15.13 csycon

`csycon` estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSYTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine csycon(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void csycon_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, const float *anorm, float *rcond,
             armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = '`U`': Upper triangular, form is `A` = U*D*U^T ; = '`L`': Lower triangular, form is `A` = L*D*L^T .

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

A Input parameter.

`A` is `COMPLEX`

`A` is an array, dimension (`LDA`, `N`). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `N`).

IPIV Input parameter.

`IPIV` is `INTEGER` array, dimension (`N`)

Details of the interchanges and the block structure of D as determined by CSYTRF.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsycon*, *ssycon* and *zsycon*. It also exists with a native C interface as *LAPACKE_csycon*.

4.15.14 csycon_3

CSYCON_3 estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization computed by CSYTRF_RK or CSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))). This routine uses BLAS3 solver CSYTRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine csycon_3(UPLO, N, A, LDA, E, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void csycon_3_(const char *uplo, const armpl_int_t *n,
               const armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_singlecomplex_t *e, const armpl_int_t *ipiv,
               const float *anorm, float *rcond, armpl_singlecomplex_t *work,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^T)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^T)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by CSYTRF_RK and CSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF_RK or CSYTRF_BK.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsycon_3*, *ssycon_3* and *zsycon_3*. It also exists with a native C interface as *LAPACKE_csycon_3*.

4.15.15 csycon_rook

CSYCON_ROOK estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by CSYTRF_ROOK.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine csycon_rook(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void csycon_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  const armpl_int_t *ipiv, const float *anorm, float *rcond,
                  armpl_singlecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF_ROOK.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsycon_rook*, *ssycon_rook* and *zsycon_rook*.

4.15.16 ctbcon

ctbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ctbcon(NORM, UPLO, DIAG, N, KD, AB, LDAB, RCOND, WORK, RWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ctbcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             float *rcond, armpl_singlecomplex_t *work, float *rwork,
             armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtbcon*, *stbcon* and *ztbcon*. It also exists with a native C interface as *LAPACKE_ctbcon*.

4.15.17 ctpcon

`ctpcon` estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ctpcon(NORM, UPLO, DIAG, N, AP, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctpcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const armpl_singlecomplex_t *ap,
             float *rcond, armpl_singlecomplex_t *work, float *rwork,
             armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= '`U`': A is upper triangular; = '`L`': A is lower triangular.

DIAG Input parameter.

`DIAG` is `CHARACTER*1`

= '`N`': A is non-unit triangular; = '`U`': A is unit triangular.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

AP Input parameter.

`AP` is `COMPLEX`

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtpcon*, *stpcon* and *ztpcon*. It also exists with a native C interface as *LAPACKE_ctpcon*.

4.15.18 ctrcon

ctrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrcon(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctrcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const armpl_singlecomplex_t *a,
             const armpl_int_t *lda, float *rcond,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *info,
             ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrcon*, *strcon* and *ztrcon*. It also exists with a native C interface as *LAPACKE_ctrcon*.

4.15.19 dgbcon

dgbcon estimates the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by DGBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgbcon(NORM, N, KL, KU, AB, LDAB, IPIV, ANORM, RCOND, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgbcon_(const char *norm, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const double *ab, const armpl_int_t *ldab,
             const armpl_int_t *ipiv, const double *anorm, double *rcond,
             double *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). Details of the LU factorization of the band matrix A, as computed by DGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIV(i).

ANORM Input parameter.

ANORM is DOUBLE PRECISION

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgbcon*, *sgbcon* and *zgbcon*. It also exists with a native C interface as *LAPACKE_dgbcon*.

4.15.20 dgecon

dgecon estimates the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by DGETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dgecon(NORM, N, A, LDA, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgecon_(const char *norm, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, const double *anorm, double *rcond,
             double *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The factors L and U from the factorization A = P*L*U as computed by DGETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ANORM Input parameter.

ANORM is DOUBLE PRECISION

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgecon*, *sgecon* and *zgecon*. It also exists with a native C interface as *LAPACKE_dgecon*.

4.15.21 dgtcon

`dgtcon` estimates the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by DGTTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine dgtcon(NORM, N, DL, D, DU, DU2, IPIV, ANORM, RCOND, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dgtcon_(const char *norm, const armpl_int_t *n, const double *dl,
             const double *d, const double *du, const double *du2,
             const armpl_int_t *ipiv, const double *anorm, double *rcond,
             double *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

DL Input parameter.

`DL` is `DOUBLE PRECISION`

`DL` is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by DGTTRF.

D Input parameter.

`D` is `DOUBLE PRECISION`

`D` is an array, dimension (`N`). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

`DU` is `DOUBLE PRECISION`

`DU` is an array, dimension (N-1). The (n-1) elements of the first superdiagonal of U.

DU2 Input parameter.

`DU2` is `DOUBLE PRECISION`

`DU2` is an array, dimension (N-2). The (n-2) elements of the second superdiagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgtcon*, *sgtcon* and *zgtcon*. It also exists with a native C interface as *LAPACKE_dgtcon*.

4.15.22 dpbcon

dpbcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization A = U^T *U or A = L*L^T computed by DPBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine dpbcon(UPLO, N, KD, AB, LDAB, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dpbcon_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const double *ab, const armpl_int_t *ldab, const double *anorm,
```

(continues on next page)

(continued from previous page)

```
                double *rcond, double *work, armpl_int_t *iwork,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor stored in AB; = 'L': Lower triangular factor stored in AB.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array AB as follows: if UPLO ='U', AB(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', AB(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm (or infinity-norm) of the symmetric band matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpbcon*, *spbcon* and *zpbcon*. It also exists with a native C interface as *LAPACKE_dpbcon*.

4.15.23 dpocon

`dpocon` estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization A = U^T *U or A = L*L^T computed by DPOTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine dpocon(UPLO, N, A, LDA, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dpocon_(const char *uplo, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, const double *anorm, double *rcond,
             double *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= 'U': Upper triangle of `A` is stored; = 'L': Lower triangle of `A` is stored.

N Input parameter.

`N` is `INTEGER`

The order of the matrix `A`. `N` >= 0.

A Input parameter.

`A` is `DOUBLE PRECISION`

`A` is an array, dimension (`LDA`, `N`). The triangular factor U or L from the Cholesky factorization `A` = U^T *U or `A` = L*L^T , as computed by DPOTRF.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `N`).

ANORM Input parameter.

`ANORM` is `DOUBLE PRECISION`

The 1-norm (or infinity-norm) of the symmetric matrix `A`.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpocon*, *spocon* and *zpocon*. It also exists with a native C interface as *LAPACKE_dpocon*.

4.15.24 dppcon

dppcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization A = U^T *U or A = L*L^T computed by DPPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine dppcon(UPLO, N, AP, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dppcon_(const char *uplo, const armpl_int_t *n, const double *ap,
             const double *anorm, double *rcond, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , packed columnwise in a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cppcon*, *sppcon* and *zppcon*. It also exists with a native C interface as *LAPACKE_dppcon*.

4.15.25 dptcon

dptcon computes the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization A = L*D*L^T or A = U^T *D*U computed by DPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

```
RCOND = 1 / (ANORM * norm(inv(A))).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dptcon(N, D, E, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void dptcon_(const armpl_int_t *n, const double *d, const double *e,
             const double *anorm, double *rcond, double *work,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization of A, as computed by DPTTRF.

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by DPTTRF.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cptcon*, *sptcon* and *zptcon*. It also exists with a native C interface as *LAPACKE_dptcon*.

4.15.26 dspcon

dspcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine dspcon(UPLO, N, AP, IPIV, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dspcon_(const char *uplo, const armpl_int_t *n, const double *ap,
             const armpl_int_t *ipiv, const double *anorm, double *rcond,
             double *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSPTRF.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cspcon*, *sspcon* and *zspcon*. It also exists with a native C interface as *LAPACKE_dspcon*.

4.15.27 dsycon

dsycon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSYTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine dsycon(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsycon_(const char *uplo, const armpl_int_t *n, const double *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv,
             const double *anorm, double *rcond, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csycon*, *ssycon* and *zsycon*. It also exists with a native C interface as *LAPACKE_dsycon*.

4.15.28 dsycon_3

DSYCON_3 estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization computed by DSYTRF_RK or DSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))). This routine uses BLAS3 solver DSYTRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsycon_3(UPLO, N, A, LDA, E, IPIV, ANORM, RCOND, WORK, IWORK,
                    INFO)
```

C specification:

```
#include "armpl.h"

void dsycon_3_(const char *uplo, const armpl_int_t *n, const double *a,
               const armpl_int_t *lda, const double *e,
               const armpl_int_t *ipiv, const double *anorm, double *rcond,
               double *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^T)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^T)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by DSYTRF_RK and DSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF_RK or DSYTRF_BK.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csycon_3*, *ssycon_3* and *zsycon_3*. It also exists with a native C interface as *LAPACKE_dsycon_3*.

4.15.29 dsycon_rook

DSYCON_ROOK estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by DSYTRF_ROOK.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine dsycon_rook(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, IWORK,
                       INFO)
```

C specification:

```
#include "armpl.h"

void dsycon_rook_(const char *uplo, const armpl_int_t *n, const double *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv,
                  const double *anorm, double *rcond, double *work,
                  armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF_ROOK.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csycon_rook*, *ssycon_rook* and *zsycon_rook*.

4.15.30 dtbcon

dtbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dtbcon(NORM, UPLO, DIAG, N, KD, AB, LDAB, RCOND, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void dtbcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd, const double *ab,
             const armpl_int_t *ldab, double *rcond, double *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

AB Input parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctbcon*, *stbcon* and *ztbcon*. It also exists with a native C interface as *LAPACKE_dtbcon*.

4.15.31 dtpcon

dtpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dtpcon(NORM, UPLO, DIAG, N, AP, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtpcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const double *ap, double *rcond,
             double *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is DOUBLE PRECISION

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpcon*, *stpcon* and *ztpcon*. It also exists with a native C interface as *LAPACKE_dtpcon*.

4.15.32 dtrcon

dtrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrcon(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtrcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const double *a, const armpl_int_t *lda,
             double *rcond, double *work, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrcon*, *strcon* and *ztrcon*. It also exists with a native C interface as *LAPACKE_dtrcon*.

4.15.33 sgbcon

sgbcon estimates the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgbcon(NORM, N, KL, KU, AB, LDAB, IPIV, ANORM, RCOND, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgbcon_(const char *norm, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const float *ab, const armpl_int_t *ldab,
             const armpl_int_t *ipiv, const float *anorm, float *rcond,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = ‘1’ or ‘O’: 1-norm; = ‘I’: Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIV(i).

ANORM Input parameter.

ANORM is REAL

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgbcon*, *dgbcon* and *zgbcon*. It also exists with a native C interface as *LAPACKE_sgbcon*.

4.15.34 sgecon

`sgecon` estimates the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sgecon(NORM, N, A, LDA, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgecon_(const char *norm, const armpl_int_t *n, const float *a,
             const armpl_int_t *lda, const float *anorm, float *rcond,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ANORM Input parameter.

ANORM is REAL

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgecon*, *dgecon* and *zgecon*. It also exists with a native C interface as *LAPACKE_sgecon*.

4.15.35 sgtcon

sgtcon estimates the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine sgtcon(NORM, N, DL, D, DU, DU2, IPIV, ANORM, RCOND, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void sgtcon_(const char *norm, const armpl_int_t *n, const float *dl,
             const float *d, const float *du, const float *du2,
             const armpl_int_t *ipiv, const float *anorm, float *rcond,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = ‘1’ or ‘O’: 1-norm; = ‘I’: Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

DL Input parameter.

DL is REAL

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is REAL

DU is an array, dimension (N-1). The (n-1) elements of the first superdiagonal of U.

DU2 Input parameter.

DU2 is REAL

DU2 is an array, dimension (N-2). The (n-2) elements of the second superdiagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

ANORM Input parameter.

ANORM is REAL

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgtcon*, *dgtcon* and *zgtcon*. It also exists with a native C interface as *LAPACKE_sgtcon*.

4.15.36 spbcon

spbcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization A = U^T *U or A = L*L^T computed by SPBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine spbcon(UPLO, N, KD, AB, LDAB, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void spbcon_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const float *ab, const armpl_int_t *ldab, const float *anorm,
             float *rcond, float *work, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor stored in AB; = 'L': Lower triangular factor stored in AB.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array AB as follows: if UPLO ='U', AB(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', AB(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

ANORM Input parameter.

ANORM is REAL

The 1-norm (or infinity-norm) of the symmetric band matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpbcon*, *dpbcon* and *zpbcon*. It also exists with a native C interface as *LAPACKE_spbcon*.

4.15.37 spocon

spocon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization A = U^T *U or A = L*L^T computed by SPOTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine spocon(UPLO, N, A, LDA, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void spocon_(const char *uplo, const armpl_int_t *n, const float *a,
             const armpl_int_t *lda, const float *anorm, float *rcond,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by SPOTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ANORM Input parameter.

ANORM is REAL

The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpocon*, *dpocon* and *zpocon*. It also exists with a native C interface as *LAPACKE_spocon*.

4.15.38 sppcon

sppcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization A = U^T *U or A = L*L^T computed by SPPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine sppcon(UPLO, N, AP, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sppcon_(const char *uplo, const armpl_int_t *n, const float *ap,
             const float *anorm, float *rcond, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , packed columnwise in a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

ANORM Input parameter.

ANORM is REAL

The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cppcon*, *dppcon* and *zppcon*. It also exists with a native C interface as *LAPACKE_sppcon*.

4.15.39 sptcon

sptcon computes the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization A = L*D*L^T or A = U^T *D*U computed by SPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

```
RCOND = 1 / (ANORM * norm(inv(A))).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine sptcon(N, D, E, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void sptcon_(const armpl_int_t *n, const float *d, const float *e,
             const float *anorm, float *rcond, float *work,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization of A, as computed by SPTTRF.

E Input parameter.

E is REAL

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by SPTTRF.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cptcon*, *dptcon* and *zptcon*. It also exists with a native C interface as *LAPACKE_sptcon*.

4.15.40 sspcon

sspcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by SSPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine sspcon(UPLO, N, AP, IPIV, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sspcon_(const char *uplo, const armpl_int_t *n, const float *ap,
             const armpl_int_t *ipiv, const float *anorm, float *rcond,
             float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSPTRF.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cspcon*, *dspcon* and *zspcon*. It also exists with a native C interface as *LAPACKE_sspcon*.

4.15.41 ssycon

ssycon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by SSYTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine ssycon(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssycon_(const char *uplo, const armpl_int_t *n, const float *a,
             const armpl_int_t *lda, const armpl_int_t *ipiv,
             const float *anorm, float *rcond, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csycon*, *dsycon* and *zsycon*. It also exists with a native C interface as *LAPACKE_ssycon*.

4.15.42 ssycon_3

SSYCON_3 estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization computed by DSYTRF_RK or DSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))). This routine uses BLAS3 solver SSYTRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssycon_3(UPLO, N, A, LDA, E, IPIV, ANORM, RCOND, WORK, IWORK,
                    INFO)
```

C specification:

```
#include "armpl.h"

void ssycon_3_(const char *uplo, const armpl_int_t *n, const float *a,
               const armpl_int_t *lda, const float *e,
               const armpl_int_t *ipiv, const float *anorm, float *rcond,
               float *work, armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^T)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^T)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by SSYTRF_RK and SSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is REAL

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF_RK or SSYTRF_BK.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csycon_3*, *dsycon_3* and *zsycon_3*. It also exists with a native C interface as *LAPACKE_ssycon_3*.

4.15.43 ssycon_rook

SSYCON_ROOK estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by SSYTRF_ROOK.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine ssycon_rook(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, IWORK,
                       INFO)
```

C specification:

```
#include "armpl.h"

void ssycon_rook_(const char *uplo, const armpl_int_t *n, const float *a,
                  const armpl_int_t *lda, const armpl_int_t *ipiv,
                  const float *anorm, float *rcond, float *work,
                  armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF_ROOK.

ANORM Input parameter.

ANORM is REAL

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csycon_rook*, *dsycon_rook* and *zsycon_rook*.

4.15.44 stbcon

`stbcon` estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine stbcon(NORM, UPLO, DIAG, N, KD, AB, LDAB, RCOND, WORK, IWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void stbcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd, const float *ab,
             const armpl_int_t *ldab, float *rcond, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

= '`U`': A is upper triangular; = '`L`': A is lower triangular.

DIAG Input parameter.

`DIAG` is `CHARACTER*1`

= '`N`': A is non-unit triangular; = '`U`': A is unit triangular.

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0.

KD Input parameter.

`KD` is `INTEGER`

The number of superdiagonals or subdiagonals of the triangular band matrix A. `KD` >= 0.

AB Input parameter.

AB is REAL

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctbcon*, *dtbcon* and *ztbcon*. It also exists with a native C interface as *LAPACKE_stbcon*.

4.15.45 stpcon

stpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine stpcon(NORM, UPLO, DIAG, N, AP, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void stpcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const float *ap, float *rcond, float *work,
             armpl_int_t *iwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is REAL

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpcon*, *dtpcon* and *ztpcon*. It also exists with a native C interface as *LAPACKE_stpcon*.

4.15.46 strcon

`strcon` estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine strcon(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void strcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const float *a, const armpl_int_t *lda,
             float *rcond, float *work, armpl_int_t *iwork, armpl_int_t *info,
             ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

RCOND Output parameter.

RCOND is REAL

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (3*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrcon*, *dtrcon* and *ztrcon*. It also exists with a native C interface as *LAPACKE_strcon*.

4.15.47 zgbcon

zgbcon estimates the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by ZGBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgbcon(NORM, N, KL, KU, AB, LDAB, IPIV, ANORM, RCOND, WORK, RWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void zgbcon_(const char *norm, const armpl_int_t *n, const armpl_int_t *kl,
             const armpl_int_t *ku, const armpl_doublecomplex_t *ab,
             const armpl_int_t *ldab, const armpl_int_t *ipiv,
             const double *anorm, double *rcond, armpl_doublecomplex_t *work,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). Details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIV(i).

ANORM Input parameter.

ANORM is DOUBLE PRECISION

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgbcon*, *dgbcon* and *sgbcon*. It also exists with a native C interface as *LAPACKE_zgbcon*.

4.15.48 zgecon

zgecon estimates the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by ZGETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zgecon(NORM, N, A, LDA, ANORM, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgecon_(const char *norm, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const double *anorm, double *rcond, armpl_doublecomplex_t *work,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The factors L and U from the factorization A = P*L*U as computed by ZGETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ANORM Input parameter.

ANORM is DOUBLE PRECISION

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgecon*, *dgecon* and *sgecon*. It also exists with a native C interface as *LAPACKE_zgecon*.

4.15.49 zgtcon

zgtcon estimates the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by ZGTTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zgtcon(NORM, N, DL, D, DU, DU2, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgtcon_(const char *norm, const armpl_int_t *n,
             const armpl_doublecomplex_t *dl, const armpl_doublecomplex_t *d,
             const armpl_doublecomplex_t *du,
```

(continues on next page)

(continued from previous page)

```
                const armpl_doublecomplex_t *du2, const armpl_int_t *ipiv,
                const double *anorm, double *rcond, armpl_doublecomplex_t *work,
                armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

DL Input parameter.

DL is COMPLEX*16

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by ZGTTRF.

D Input parameter.

D is COMPLEX*16

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is COMPLEX*16

DU is an array, dimension (N-1). The (n-1) elements of the first superdiagonal of U.

DU2 Input parameter.

DU2 is COMPLEX*16

DU2 is an array, dimension (N-2). The (n-2) elements of the second superdiagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cgtcon*, *dgtcon* and *sgtcon*. It also exists with a native C interface as *LAPACKE_zgtcon*.

4.15.50 zhecon

zhecon estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by ZHETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zhecon(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhecon_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, const double *anorm, double *rcond,
             armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *checon*. It also exists with a native C interface as *LAPACKE_zhecon*.

4.15.51 zhecon_3

ZHECON_3 estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian matrix A using the factorization computed by ZHETRF_RK or ZHETRF_BK:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))). This routine uses BLAS3 solver ZHETRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhecon_3(UPLO, N, A, LDA, E, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhecon_3_(const char *uplo, const armpl_int_t *n,
               const armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_doublecomplex_t *e, const armpl_int_t *ipiv,
               const double *anorm, double *rcond,
               armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^H)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^H)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by ZHETRF_RK and ZHETRF_BK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF_RK or ZHETRF_BK.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *checon_3*. It also exists with a native C interface as *LAPACKE_zhecon_3*.

4.15.52 zhecon_rook

ZHECON_ROOK estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by CHETRF_ROOK.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zhecon_rook(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhecon_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                  const armpl_int_t *ipiv, const double *anorm, double *rcond,
                  armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF_ROOK.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *checon_rook*.

4.15.53 zhpcon

zhpcon estimates the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization A = U*D*U^H or A = L*D*L^H computed by ZHPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zhpcon(UPLO, N, AP, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhpcon_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *ap, const armpl_int_t *ipiv,
             const double *anorm, double *rcond, armpl_doublecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHPTRF.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chpcon*. It also exists with a native C interface as *LAPACKE_zhpcon*.

4.15.54 zpbcon

zpbcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization A = U^H *U or A = L*L^H computed by ZPBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zpbcon(UPLO, N, KD, AB, LDAB, ANORM, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zpbcon_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             const double *anorm, double *rcond, armpl_doublecomplex_t *work,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangular factor stored in AB; = 'L': Lower triangular factor stored in AB.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array AB as follows: if UPLO ='U', AB(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', AB(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm (or infinity-norm) of the Hermitian band matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpbcon*, *dpbcon* and *spbcon*. It also exists with a native C interface as *LAPACKE_zpbcon*.

4.15.55 zpocon

zpocon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization A = U^H *U or A = L*L^H computed by ZPOTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zpocon(UPLO, N, A, LDA, ANORM, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zpocon_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const double *anorm, double *rcond, armpl_doublecomplex_t *work,
             double *rwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by ZPOTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cpocon*, *dpocon* and *spocon*. It also exists with a native C interface as *LAPACKE_zpocon*.

4.15.56 zppcon

zppcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization A = U^H *U or A = L*L^H computed by ZPPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zppcon(UPLO, N, AP, ANORM, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zppcon_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *ap, const double *anorm,
             double *rcond, armpl_doublecomplex_t *work, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , packed columnwise in a linear array. The j-th column of U or L is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cppcon*, *dppcon* and *sppcon*. It also exists with a native C interface as *LAPACKE_zppcon*.

4.15.57 zptcon

`zptcon` computes the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization A = L*D*L^H or A = U^H *D*U computed by ZPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

```
RCOND = 1 / (ANORM * norm(inv(A))).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine zptcon(N, D, E, ANORM, RCOND, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zptcon_(const armpl_int_t *n, const double *d,
             const armpl_doublecomplex_t *e, const double *anorm,
             double *rcond, double *rwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

D Input parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization of A, as computed by ZPTTRF.

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N-1). The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by ZPTTRF.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the 1-norm of inv(A) computed in this routine.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cptcon*, *dptcon* and *sptcon*. It also exists with a native C interface as *LAPACKE_zptcon*.

4.15.58 zspcon

zspcon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zspcon(UPLO, N, AP, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zspcon_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *ap, const armpl_int_t *ipiv,
             const double *anorm, double *rcond, armpl_doublecomplex_t *work,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSPTRF.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *cspcon*, *dspcon* and *sspcon*. It also exists with a native C interface as *LAPACKE_zspcon*.

4.15.59 zsycon

zsycon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSYTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zsycon(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsycon_(const char *uplo, const armpl_int_t *n,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             const armpl_int_t *ipiv, const double *anorm, double *rcond,
             armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csycon*, *dsycon* and *ssycon*. It also exists with a native C interface as *LAPACKE_zsycon*.

4.15.60 zsycon_3

ZSYCON_3 estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization computed by ZSYTRF_RK or ZSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))). This routine uses BLAS3 solver ZSYTRS_3.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsycon_3(UPLO, N, A, LDA, E, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsycon_3_(const char *uplo, const armpl_int_t *n,
               const armpl_doublecomplex_t *a, const armpl_int_t *lda,
               const armpl_doublecomplex_t *e, const armpl_int_t *ipiv,
               const double *anorm, double *rcond,
               const armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: = 'U': Upper triangular, form is A = P*U*D*(U^T)*(P^T); = 'L': Lower triangular, form is A = P*L*D*(L^T)*(P^T).

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Diagonal of the block diagonal matrix D and factors U or L as computed by ZSYTRF_RK and ZSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF_RK or ZSYTRF_BK.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csycon_3*, *dsycon_3* and *ssycon_3*. It also exists with a native C interface as *LAPACKE_zsycon_3*.

4.15.61 zsycon_rook

ZSYCON_ROOK estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization A = U*D*U^T or A = L*D*L^T computed by ZSYTRF_ROOK.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Syntax

Fortran specification:

```
use armpl_library

subroutine zsycon_rook(UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsycon_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_doublecomplex_t *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                    const armpl_int_t *ipiv, const double *anorm, double *rcond,
                    armpl_doublecomplex_t *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF_ROOK.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF_ROOK.

ANORM Input parameter.

ANORM is DOUBLE PRECISION

The 1-norm of the original matrix A.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csycon_rook*, *dsycon_rook* and *ssycon_rook*.

4.15.62 ztbcon

ztbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ztbcon(NORM, UPLO, DIAG, N, KD, AB, LDAB, RCOND, WORK, RWORK,
                  INFO)
```

C specification:

```
#include "armpl.h"

void ztbcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
             double *rcond, armpl_doublecomplex_t *work, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

AB Input parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctbcon*, *dtbcon* and *stbcon*. It also exists with a native C interface as *LAPACKE_ztbcon*.

4.15.63 ztpcon

ztpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ztpcon(NORM, UPLO, DIAG, N, AP, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztpcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const armpl_doublecomplex_t *ap,
             double *rcond, armpl_doublecomplex_t *work, double *rwork,
             armpl_int_t *info, ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctpcon*, *dtpcon* and *stpcon*. It also exists with a native C interface as *LAPACKE_ztpcon*.

4.15.64 ztrcon

`ztrcon` estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrcon(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztrcon_(const char *norm, const char *uplo, const char *diag,
             const armpl_int_t *n, const armpl_doublecomplex_t *a,
             const armpl_int_t *lda, double *rcond,
             armpl_doublecomplex_t *work, double *rwork, armpl_int_t *info,
             ... );
```

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies whether the 1-norm condition number or the infinity-norm condition number is required: = '1' or 'O': 1-norm; = 'I': Infinity-norm.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

RCOND Output parameter.

RCOND is DOUBLE PRECISION

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (2*N) .

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrcon*, *dtrcon* and *strcon*. It also exists with a native C interface as *LAPACKE_ztrcon*.

4.16 LAPACK lapack routines routines

4.16.1 cgetsls

cgetsls solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, using a tall sk

The following options are provided:

* If TRANS = 'N' and m >= n: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize || B - A*X ||.

* If TRANS = 'N' and m < n: find the minimum norm solution of an underdetermined system A * X = B.

* If TRANS = 'C' and m >= n: find the minimum norm solution of an undetermined system A^T * X = B.

* If TRANS = 'C' and m < n: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize || B - A^T * X ||.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgetsls(TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgetsls_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
              const armpl_int_t *lda, armpl_singlecomplex_t *b,
              const armpl_int_t *ldb, armpl_singlecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': the linear system involves A; = 'C': the linear system involves A^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >=0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A is overwritten by details of its QR or LQ factorization as returned by CGEQR or CGELQ.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'C'. On exit, if INFO = 0, B is overwritten by the solution vectors, stored columnwise: if TRANS = 'N' and m >= n, rows 1 to n of B contain the least squares solution vectors. if TRANS = 'N' and m < n, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'C' and m >= n, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'C' and m < n, rows 1 to M of B contain the least squares solution vectors.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= MAX(1, M, N).

WORK Output parameter.

(workspace) COMPLEX

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *dgetsls*, *sgetsls* and *zgetsls*. It also exists with a native C interface as *LAPACKE_cgetsls*.

4.16.2 chb2st_kernels

CHB2ST_KERNELS is an internal routine used by the CHETRD_HB2ST subroutine.

Syntax

Fortran specification:

```
use armpl_library

subroutine chb2st_kernels(UPLO, WANTZ, TTYPE, ST, ED, SWEEP, N, NB, IB, A,
                          LDA, V, TAU, LDVT, WORK)
```

C specification:

```
#include "armpl.h"

void chb2st_kernels_(const char *uplo, const armpl_int_t *wantz,
                     const armpl_int_t *ttype, const armpl_int_t *st,
                     const armpl_int_t *ed, const armpl_int_t *sweep,
                     const armpl_int_t *n, const armpl_int_t *nb,
                     const armpl_int_t *ib, armpl_singlecomplex_t *a,
                     const armpl_int_t *lda, armpl_singlecomplex_t *v,
                     armpl_singlecomplex_t *tau, const armpl_int_t *ldvt,
                     const armpl_singlecomplex_t *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

WANTZ Input parameter.

WANTZ is LOGICAL which indicate if Eigenvalue are requested or both

Eigenvalue/Eigenvectors.

TTYPE Input parameter.

TTYPE is INTEGER

ST Input parameter.

ST is INTEGER

internal parameter for indices.

ED Input parameter.

ED is INTEGER

internal parameter for indices.

SWEEP Input parameter.

SWEEP is INTEGER

internal parameter for indices.

N Input parameter.

N is INTEGER. The order of the matrix A.

NB Input parameter.

NB is INTEGER. The size of the band.

IB Input parameter.

IB is INTEGER.

A Input and output parameter.

A is COMPLEX array. A pointer to the matrix A.

LDA Input parameter.

LDA is INTEGER. The leading dimension of the matrix A.

V Output parameter.

V is COMPLEX

V is an array, dimension 2*n if eigenvalues only are. requested or to be queried for vectors.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (2*n).. The scalar factors of the Householder reflectors are stored in this array.

LDVT Input parameter.

LDVT is INTEGER.

WORK Input parameter.

WORK is COMPLEX array. Workspace of size nb.

Related Information

For this routine in other precisions, please see *zhb2st_kernels*.

4.16.3 chbev_2stage

CHBEV_2STAGE computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A using the 2stage technique for the reduction to tridiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbev_2stage(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK,
                        RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chbev_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                   const armpl_int_t *kd, armpl_singlecomplex_t *ab,
                   const armpl_int_t *ldab, float *w,
                   armpl_singlecomplex_t *z, const armpl_int_t *ldz,
                   armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                   float *rwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension LWORK. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (max(1,3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *zhbev_2stage*. It also exists with a native C interface as *LAPACKE_chbev_2stage*.

4.16.4 chbevd_2stage

CHBEVD_2STAGE computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbevd_2stage(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK,
                         RWORK, LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chbevd_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                    const armpl_int_t *kd, armpl_singlecomplex_t *ab,
                    const armpl_int_t *ldab, float *w,
                    armpl_singlecomplex_t *z, const armpl_int_t *ldz,
                    armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                    float *rwork, const armpl_int_t *lrwork,
                    armpl_int_t *iwork, const armpl_int_t *liwork,
                    armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array,. dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5* N .

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *zhbevd_2stage*. It also exists with a native C interface as *LAPACKE_chbevd_2stage*.

4.16.5 chbevx_2stage

CHBEVX_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine chbevx_2stage(JOBZ, RANGE, UPLO, N, KD, AB, LDAB, Q, LDQ, VL, VU,
                         IL, IU, ABSTOL, M, W, Z, LDZ, WORK, LWORK, RWORK,
                         IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void chbevx_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, const armpl_int_t *kd,
                    armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
                    armpl_singlecomplex_t *q, const armpl_int_t *ldq,
                    const float *vl, const float *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const float *abstol,
                    armpl_int_t *m, float *w, armpl_singlecomplex_t *z,
                    const armpl_int_t *ldz, armpl_singlecomplex_t *work,
                    const armpl_int_t *lwork, float *rwork,
                    armpl_int_t *iwork, armpl_int_t *ifail, armpl_int_t *info,
                    ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

Q Output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the N-by-N unitary matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AB to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *zhbevx_2stage*. It also exists with a native C interface as *LAPACKE_chbevx_2stage*.

4.16.6 cheev_2stage

CHEEV_2STAGE computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A using the 2stage technique for the reduction to tridiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheev_2stage(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cheev_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                   armpl_singlecomplex_t *a, const armpl_int_t *lda, float *w,
                   armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                   float *rwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

4.16.7 cheevd_2stage

CHEEVD_2STAGE computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheevd_2stage(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, RWORK, LRWORK,
                         IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cheevd_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                    armpl_singlecomplex_t *a, const armpl_int_t *lda,
                    float *w, armpl_singlecomplex_t *work,
                    const armpl_int_t *lwork, float *rwork,
                    const armpl_int_t *lrwork, armpl_int_t *iwork,
                    const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N+1 = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N+1 where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be at least 2* N + N**2

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array,. dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *zheevd_2stage*. It also exists with a native C interface as *LAPACKE_cheevd_2stage*.

4.16.8 cheevr_2stage

CHEEVR_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

CHEEVR_2STAGE first reduces the matrix A to tridiagonal form T with a call to CHETRD. Then, whenever possible, CHEEVR_2STAGE calls CSTEMR to compute eigenspectrum using Relatively Robust Representations. CSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
    define all the wanted eigenvalues to high relative accuracy.
    This means that small relative changes in the entries of D and L
    cause only small relative changes in the eigenvalues and
    eigenvectors. The standard (unfactored) representation of the
    tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
    If the eigenvectors are desired, the algorithm attains full
    accuracy of the computed eigenvalues only right before
    the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
    shift close to the cluster, find a new factorization, and refine
    the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
    the corresponding eigenvector by forming a rank revealing twisted
    factorization. Go back to (c) for any clusters that remain.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see DSTEMR's documentation and: - Inderjit S. Dhillon and Beresford N. Parlett: "Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

- Inderjit Dhillon and Beresford Parlett: "Orthogonal Eigenvectors and

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

- Inderjit Dhillon: "A new O(n^2) algorithm for the symmetric

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Note 1 : CHEEVR_2STAGE calls CSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. CHEEVR_2STAGE calls SSTEBZ and CSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of CSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheevr_2stage(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL,
                         M, W, Z, LDZ, ISUPPZ, WORK, LWORK, RWORK, LRWORK,
                         IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cheevr_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, armpl_singlecomplex_t *a,
                    const armpl_int_t *lda, const float *vl, const float *vu,
                    const armpl_int_t *il, const armpl_int_t *iu,
                    const float *abstol, armpl_int_t *m, float *w,
                    armpl_singlecomplex_t *z, const armpl_int_t *ldz,
                    armpl_int_t *isuppz, armpl_singlecomplex_t *work,
                    const armpl_int_t *lwork, float *rwork,
                    const armpl_int_t *lrwork, armpl_int_t *iwork,
                    const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= ‘A’: all eigenvalues will be found. = ‘V’: all eigenvalues in the half-open interval (VL,VU] will be found. = ‘I’: the IL-th through IU-th eigenvalues will be found. For RANGE = ‘V’ or ‘I’ and IU - IL < N - 1, SSTEBZ and CSTEIN are called

UPLO Input parameter.

UPLO is CHARACTER*1

= ‘U’: Upper triangle of A is stored; = ‘L’: Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = ‘U’, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = ‘L’, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO=’L’) or the upper triangle (if UPLO=’U’) of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE=’V’, the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = ‘A’ or ‘I’.

VU Input parameter.

VU is REAL

If RANGE=’V’, the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = ‘A’ or ‘I’.

IL Input parameter.

IL is INTEGER

If RANGE=’I’, the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = ‘A’ or ‘V’.

IU Input parameter.

IU is INTEGER

If RANGE=’I’, the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = ‘A’ or ‘V’.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See “Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy,” by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but furutre releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is an output of CSTEMR (tridiagonal matrix). The support of the eigenvectors of A is typically 1:N because of the unitary transformations applied by CUNMTR. Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, 26*N, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal (and minimal) LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The length of the array RWORK. LRWORK >= max(1,24*N).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

Related Information

For this routine in other precisions, please see *zheevr_2stage*. It also exists with a native C interface as *LAPACKE_cheevr_2stage*.

4.16.9 cheevx_2stage

CHEEVX_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheevx_2stage(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL,
                         M, W, Z, LDZ, WORK, LWORK, RWORK, IWORK, IFAIL,
                         INFO)
```

C specification:

```
#include "armpl.h"

void cheevx_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, armpl_singlecomplex_t *a,
                    const armpl_int_t *lda, const float *vl, const float *vu,
```

(continues on next page)

(continued from previous page)

```
                    const armpl_int_t *il, const armpl_int_t *iu,
                    const float *abstol, armpl_int_t *m, float *w,
                    armpl_singlecomplex_t *z, const armpl_int_t *ldz,
                    armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                    float *rwork, armpl_int_t *iwork, armpl_int_t *ifail,
                    armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, 8*N, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N where KD

is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *zheevx_2stage*. It also exists with a native C interface as *LAPACKE_cheevx_2stage*.

4.16.10 chegv_2stage

CHEGV_2STAGE computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. This routine use the 2stage technique for the reduction to tridiagonal which showed higher performance on recent architecture and for large sizes N>2000.

Syntax

Fortran specification:

```
use armpl_library

subroutine chegv_2stage(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK,
                        RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chegv_2stage_(const armpl_int_t *itype, const char *jobz,
                   const char *uplo, const armpl_int_t *n,
                   armpl_singlecomplex_t *a, const armpl_int_t *lda,
                   armpl_singlecomplex_t *b, const armpl_int_t *ldb, float *w,
                   armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                   float *rwork, armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B*Z = I; if ITYPE = 3, Z^H *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, the Hermitian positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: CPOTRF or CHEEV returned an error code: <= N: if INFO = i, CHEEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *zhegv_2stage*. It also exists with a native C interface as *LAPACKE_chegv_2stage*.

4.16.11 chesv_aa_2stage

CHESV_AA_2STAGE computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

Aasen's 2-stage algorithm is used to factor A as

```
A = U * T * U**H,  if UPLO = 'U', or
A = L * T * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is Hermitian and band. The matrix T is then LU-factored with partial pivoting. The factored form of A is then used to solve the system of equations A * X = B.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chesv_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                           LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chesv_aa_2stage_(const char *uplo, const armpl_int_t *n,
                      const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
                      const armpl_int_t *lda, armpl_singlecomplex_t *tb,
                      const armpl_int_t *ltb, armpl_int_t *ipiv,
                      armpl_int_t *ipiv2, armpl_singlecomplex_t *b,
                      const armpl_int_t *ldb, armpl_singlecomplex_t *work,
                      const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *zhesv_aa_2stage*. It also exists with a native C interface as *LAPACKE_chesv_aa_2stage*.

4.16.12 chetf2_rk

CHETF2_RK computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetf2_rk(UPLO, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void chetf2_rk_(const char *uplo, const armpl_int_t *n,
                armpl_singlecomplex_t *a, const armpl_int_t *lda,
                armpl_singlecomplex_t *e, armpl_int_t *ipiv,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

4.16.13 chetrd_2stage

CHETRD_2STAGE reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q1^H$ $Q2^H$ * A * Q2 * Q1 = T.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrd_2stage(VECT, UPLO, N, A, LDA, D, E, TAU, HOUS2, LHOUS2,
                         WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetrd_2stage_(const char *vect, const char *uplo, const armpl_int_t *n,
                    armpl_singlecomplex_t *a, const armpl_int_t *lda,
                    float *d, float *e, armpl_singlecomplex_t *tau,
                    armpl_singlecomplex_t *hous2, const armpl_int_t *lhous2,
                    armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                    armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': No need for the Housholder representation, in particular for the second stage (Band to tridiagonal) and thus LHOUS2 is of size max(1, 4*N); = 'V': the Householder representation is needed to either generate Q1 Q2 or to apply Q1 Q2, then LHOUS2 is to be queried and computed. (NOT AVAILABLE IN THIS RELEASE).

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the band superdiagonal of A are overwritten by the corresponding elements of the internal band-diagonal matrix AB, and the elements above the KD superdiagonal, with the array TAU, represent the unitary matrix Q1 as a product of elementary reflectors; if UPLO = 'L', the diagonal and band subdiagonal of A are overwritten by the corresponding elements of the internal band-diagonal matrix AB, and the elements below the KD subdiagonal, with the array TAU, represent the unitary matrix Q1 as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (N-KD). The scalar factors of the elementary reflectors of the first stage (see Further Details).

HOUS2 Output parameter.

HOUS2 is COMPLEX

HOUS2 is an array, dimension LHOUS2, that. store the Householder representation of the stage2 band to tridiagonal.

LHOUS2 Input parameter.

LHOUS2 is INTEGER

The dimension of the array HOUS2. LHOUS2 = MAX(1, dimension) If LWORK = -1, or LHOUS2=-1, then a query is assumed; the routine only calculates the optimal size of the HOUS2 array, returns this value as the first entry of the HOUS2 array, and no error message related to LHOUS2 is issued by XERBLA. LHOUS2 = MAX(1, dimension) where dimension = 4* N if VECT='N' not available now if VECT='H'

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK = MAX(1, dimension) If LWORK = -1, or LHOUS2=-1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhetrd_2stage*.

4.16.14 chetrd_he2hb

CHETRD_HE2HB reduces a complex Hermitian matrix A to complex Hermitian band-diagonal form AB by a unitary similarity transformation: Q^H * A * Q = AB.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrd_he2hb(UPLO, N, KD, A, LDA, AB, LDAB, TAU, WORK, LWORK,
                        INFO)
```

C specification:

```
#include "armpl.h"

void chetrd_he2hb_(const char *uplo, const armpl_int_t *n,
                   const armpl_int_t *kd, armpl_singlecomplex_t *a,
                   const armpl_int_t *lda, armpl_singlecomplex_t *ab,
                   const armpl_int_t *ldab, armpl_singlecomplex_t *tau,
                   armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                   armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the reduced matrix if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0. The reduced matrix is stored in the array AB.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AB Output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On exit, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB

as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (N-KD). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK). On exit, if INFO = 0, or if LWORK=-1, WORK(1) returns the size of LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK which should be calculated by a workspace query. LWORK = MAX(1, LWORK_QUERY) If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA. LWORK_QUERY = N* KD + N*max(KD,FACTOPTNB) + 2*KD*KD where FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice otherwise putting LWORK=-1 will provide the size of WORK.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhetrd_he2hb*.

4.16.15 chetrf_aa_2stage

CHETRF_AA_2STAGE computes the factorization of a real hermitian matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a hermitian band matrix with the bandwidth of NB (NB is internally selected and stored in TB(1), and T is LU factorized with partial pivoting).

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrf_aa_2stage(UPLO, N, A, LDA, TB, LTB, IPIV, IPIV2, WORK,
                            LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void chetrf_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       armpl_singlecomplex_t *a, const armpl_int_t *lda,
                       armpl_singlecomplex_t *tb, const armpl_int_t *ltb,
                       armpl_int_t *ipiv, armpl_int_t *ipiv2,
                       armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                       armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is COMPLEX workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *zhetrf_aa_2stage*. It also exists with a native C interface as *LAPACKE_chetrf_aa_2stage*.

4.16.16 chetri_3x

CHETRI_3X computes the inverse of a complex Hermitian indefinite matrix A using the factorization computed by CHETRF_RK or CHETRF_BK:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetri_3x(UPLO, N, A, LDA, E, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void chetri_3x_(const char *uplo, const armpl_int_t *n,
                armpl_singlecomplex_t *a, const armpl_int_t *lda,
                const armpl_singlecomplex_t *e, const armpl_int_t *ipiv,
                armpl_singlecomplex_t *work, const armpl_int_t *nb,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by CHETRF_RK and CHETRF_BK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the Hermitian inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF_RK or CHETRF_BK.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N+NB+1,NB+3). .

NB Input parameter.

NB is INTEGER

Block size.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *zhetri_3x*.

4.16.17 chetrs_aa_2stage

CHETRS_AA_2STAGE solves a system of linear equations A*X = B with a real hermitian matrix A using the factorization A = U*T*U^T or A = L*T*L^T computed by CHETRF_AA_2STAGE.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetrs_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                            LDB, INFO)
```

C specification:

```
#include "armpl.h"

void chetrs_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       const armpl_int_t *nrhs,
                       const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                       armpl_singlecomplex_t *tb, const armpl_int_t *ltb,
                       const armpl_int_t *ipiv, const armpl_int_t *ipiv2,
                       armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                       armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Details of factors computed by CHETRF_AA_2STAGE.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX

TB is an array, dimension (LTB). Details of factors computed by CHETRF_AA_2STAGE.

LTB Input parameter.

The size of the array TB. LTB >= 4*N.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by CHETRF_AA_2STAGE.

IPIV2 Input parameter.

IPIV2 is INTEGER array, dimension (N)

Details of the interchanges as computed by CHETRF_AA_2STAGE.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *zhetrs_aa_2stage*. It also exists with a native C interface as *LAPACKE_chetrs_aa_2stage*.

4.16.18 chptrs

chptrs solves a system of linear equations A*X = B with a complex Hermitian matrix A stored in packed format using the factorization A = U*D*U^H or A = L*D*L^H computed by CHPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine chptrs(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void chptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *ap, const armpl_int_t *ipiv,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHPTRF.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

4.16.19 clahef_rk

CLAHEF_RK computes a partial factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**H U22**H )
```

A = (L11 0) (D 0) ($L11^H$ $L21^H$) if UPLO = 'L',

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

CLAHEF_RK is an auxiliary routine called by CHETRF_RK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine clahef_rk(UPLO, N, NB, KB, A, LDA, E, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void clahef_rk_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
                armpl_int_t *kb, armpl_singlecomplex_t *a,
                const armpl_int_t *lda, armpl_singlecomplex_t *e,
                armpl_int_t *ipiv, armpl_singlecomplex_t *w,
                const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,N-KB+1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,N-KB+1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,N-KB+1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

W Output parameter.

W is COMPLEX

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *zlahef_rk*.

4.16.20 clasyf_rk

CLASYF_RK computes a partial factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L',

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

CLASYF_RK is an auxiliary routine called by CSYTRF_RK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine clasyf_rk(UPLO, N, NB, KB, A, LDA, E, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void clasyf_rk_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
                armpl_int_t *kb, armpl_singlecomplex_t *a,
                const armpl_int_t *lda, armpl_singlecomplex_t *e,
                armpl_int_t *ipiv, armpl_singlecomplex_t *w,
                const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,N-KB+1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,N-KB+1:N). If -IPIV(k) = k, no interchange

occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,N-KB+1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

W Output parameter.

W is COMPLEX

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

4.16.21 csyconvf

If parameter WAY = 'C': CSYCONVF converts the factorization output format used in CSYTRF provided on entry in parameter A into the factorization output format used in CSYTRF_RK (or CSYTRF_BK) that is stored on exit in parameters A and E. It also coverts in place details of the intechanges stored in IPIV from the format used in CSYTRF into the format used in CSYTRF_RK (or CSYTRF_BK).

If parameter WAY = 'R': CSYCONVF performs the conversion in reverse direction, i.e. converts the factorization output format used in CSYTRF_RK (or CSYTRF_BK) provided on entry in parameters A and E into the factorization output format used in CSYTRF that is stored on exit in parameter A. It also coverts in place details of the intechanges stored in IPIV from the format used in CSYTRF_RK (or CSYTRF_BK) into the format used in CSYTRF.

CSYCONVF can also convert in Hermitian matrix case, i.e. between formats used in CHETRF and CHETRF_RK (or CHETRF_BK).

Syntax

Fortran specification:

```
use armpl_library

subroutine csyconvf(UPLO, WAY, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void csyconvf_(const char *uplo, const char *way, const armpl_int_t *n,
               armpl_singlecomplex_t *a, const armpl_int_t *lda,
               armpl_singlecomplex_t *e, armpl_int_t *ipiv, armpl_int_t *info,
               ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix A. = 'U': Upper triangular = 'L': Lower triangular

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). 1) If WAY ='C':

On entry, contains factorization details in format used in CSYTRF: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

On exit, contains factorization details in format used in CSYTRF_RK or CSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

2) If WAY = 'R':

On entry, contains factorization details in format used in CSYTRF_RK or CSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, contains factorization details in format used in CSYTRF: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input and output parameter.

E is COMPLEX

E is an array, dimension (N). 1) If WAY ='C':

On entry, just a workspace.

On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

2) If WAY = 'R':

On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

On exit, is not changed

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

1) If WAY ='C': On entry, details of the interchanges and the block structure of D in the format used in CSYTRF. On exit, details of the interchanges and the block structure of D in the format used in CSYTRF_RK (or CSYTRF_BK).

1) If WAY ='R': On entry, details of the interchanges and the block structure of D in the format used in CSYTRF_RK (or CSYTRF_BK). On exit, details of the interchanges and the block structure of D in the format used in CSYTRF.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsyconvf*, *ssyconvf* and *zsyconvf*.

4.16.22 csyconvf_rook

If parameter WAY = 'C': CSYCONVF_ROOK converts the factorization output format used in CSYTRF_ROOK provided on entry in parameter A into the factorization output format used in CSYTRF_RK (or CSYTRF_BK) that is stored on exit in parameters A and E. IPIV format for CSYTRF_ROOK and CSYTRF_RK (or CSYTRF_BK) is the same and is not converted.

If parameter WAY = 'R': CSYCONVF_ROOK performs the conversion in reverse direction, i.e. converts the factorization output format used in CSYTRF_RK (or CSYTRF_BK) provided on entry in parameters A and E into the factorization output format used in CSYTRF_ROOK that is stored on exit in parameter A. IPIV format for CSYTRF_ROOK and CSYTRF_RK (or CSYTRF_BK) is the same and is not converted.

CSYCONVF_ROOK can also convert in Hermitian matrix case, i.e. between formats used in CHETRF_ROOK and CHETRF_RK (or CHETRF_BK).

Syntax

Fortran specification:

```
use armpl_library

subroutine csyconvf_rook(UPLO, WAY, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void csyconvf_rook_(const char *uplo, const char *way, const armpl_int_t *n,
                    armpl_singlecomplex_t *a, const armpl_int_t *lda,
                    armpl_singlecomplex_t *e, const armpl_int_t *ipiv,
                    armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix A. = 'U': Upper triangular = 'L': Lower triangular

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). 1) If WAY ='C':

On entry, contains factorization details in format used in CSYTRF_ROOK: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

On exit, contains factorization details in format used in CSYTRF_RK or CSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

2) If WAY = 'R':

On entry, contains factorization details in format used in CSYTRF_RK or CSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, contains factorization details in format used in CSYTRF_ROOK: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input and output parameter.

E is COMPLEX

E is an array, dimension (N). 1) If WAY ='C':

On entry, just a workspace.

On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

2) If WAY = 'R':

On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

On exit, is not changed

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

On entry, details of the interchanges and the block structure of D as determined: 1) by CSYTRF_ROOK, if WAY ='C'; 2) by CSYTRF_RK (or CSYTRF_BK), if WAY ='R'. The IPIV format is the same for all these routines.

On exit, is not changed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsyconvf_rook*, *ssyconvf_rook* and *zsyconvf_rook*.

4.16.23 csysv_aa_2stage

CSYSV_AA_2STAGE computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Aasen's 2-stage algorithm is used to factor A as

```
A = U * T * U**H,  if UPLO = 'U', or
A = L * T * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is symmetric and band. The matrix T is then LU-factored with partial pivoting. The factored form of A is then used to solve the system of equations A * X = B.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csysv_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                           LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csysv_aa_2stage_(const char *uplo, const armpl_int_t *n,
                      const armpl_int_t *nrhs, armpl_singlecomplex_t *a,
                      const armpl_int_t *lda, armpl_singlecomplex_t *tb,
                      const armpl_int_t *ltb, armpl_int_t *ipiv,
                      armpl_int_t *ipiv2, armpl_singlecomplex_t *b,
                      const armpl_int_t *ldb, armpl_singlecomplex_t *work,
                      const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *dsysv_aa_2stage*, *ssysv_aa_2stage* and *zsysv_aa_2stage*. It also exists with a native C interface as *LAPACKE_csysv_aa_2stage*.

4.16.24 csytf2_rk

CSYTF2_RK computes the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytf2_rk(UPLO, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void csytf2_rk_(const char *uplo, const armpl_int_t *n,
                armpl_singlecomplex_t *a, const armpl_int_t *lda,
                armpl_singlecomplex_t *e, armpl_int_t *ipiv,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *dsytf2_rk*, *ssytf2_rk* and *zsytf2_rk*.

4.16.25 csytrf_aa_2stage

CSYTRF_AA_2STAGE computes the factorization of a complex symmetric matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a complex symmetric band matrix with the bandwidth of NB (NB is internally selected and stored in TB(1), and T is LU factorized with partial pivoting).

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrf_aa_2stage(UPLO, N, A, LDA, TB, LTB, IPIV, IPIV2, WORK,
                            LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void csytrf_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       armpl_singlecomplex_t *a, const armpl_int_t *lda,
                       armpl_singlecomplex_t *tb, const armpl_int_t *ltb,
                       armpl_int_t *ipiv, armpl_int_t *ipiv2,
                       armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                       armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is COMPLEX workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *dsytrf_aa_2stage*, *ssytrf_aa_2stage* and *zsytrf_aa_2stage*. It also exists with a native C interface as *LAPACKE_csytrf_aa_2stage*.

4.16.26 csytri_3x

CSYTRI_3X computes the inverse of a complex symmetric indefinite matrix A using the factorization computed by CSYTRF_RK or CSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytri_3x(UPLO, N, A, LDA, E, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void csytri_3x_(const char *uplo, const armpl_int_t *n,
                armpl_singlecomplex_t *a, const armpl_int_t *lda,
                const armpl_singlecomplex_t *e, const armpl_int_t *ipiv,
                armpl_singlecomplex_t *work, const armpl_int_t *nb,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by CSYTRF_RK and CSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the symmetric inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF_RK or CSYTRF_BK.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N+NB+1,NB+3). .

NB Input parameter.

NB is INTEGER

Block size.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *dsytri_3x*, *ssytri_3x* and *zsytri_3x*.

4.16.27 csytrs_aa_2stage

CSYTRS_AA_2STAGE solves a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*T*U^T or A = L*T*L^T computed by CSYTRF_AA_2STAGE.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytrs_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                            LDB, INFO)
```

C specification:

```
#include "armpl.h"

void csytrs_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       const armpl_int_t *nrhs,
                       const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                       armpl_singlecomplex_t *tb, const armpl_int_t *ltb,
                       const armpl_int_t *ipiv, const armpl_int_t *ipiv2,
                       armpl_singlecomplex_t *b, const armpl_int_t *ldb,
                       armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). Details of factors computed by CSYTRF_AA_2STAGE.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX

TB is an array, dimension (LTB). Details of factors computed by CSYTRF_AA_2STAGE.

LTB Input parameter.

The size of the array TB. LTB >= 4*N.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by CSYTRF_AA_2STAGE.

IPIV2 Input parameter.

IPIV2 is INTEGER array, dimension (N)

Details of the interchanges as computed by CSYTRF_AA_2STAGE.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsytrs_aa_2stage*, *ssytrs_aa_2stage* and *zsytrs_aa_2stage*. It also exists with a native C interface as *LAPACKE_csytrs_aa_2stage*.

4.16.28 ctrevc3

ctrevc3 computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T. Matrices of this type are produced by the Schur factorization of a complex general matrix: A = Q*T*Q^H , as computed by CHSEQR.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
T*x = w*x,      (y**H)*T = w*(y**H)
```

where y^H denotes the conjugate transpose of the vector y. The eigenvalues are not input to this routine, but are read directly from the diagonal of T.

This routine returns the matrices X and/or Y of right and left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input matrix. If Q is the unitary factor that reduces a matrix A to Schur form T, then Q*X and Q*Y are the matrices of right and left eigenvectors of A.

This uses a Level 3 BLAS version of the back transformation.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrevc3(SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, MM, M,
                   WORK, LWORK, RWORK, LRWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ctrevc3_(const char *side, const char *howmny, const armpl_int_t *select,
              const armpl_int_t *n, armpl_singlecomplex_t *t,
              const armpl_int_t *ldt, armpl_singlecomplex_t *vl,
              const armpl_int_t *ldvl, armpl_singlecomplex_t *vr,
              const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
              armpl_singlecomplex_t *work, const armpl_int_t *lwork,
              float *rwork, const armpl_int_t *lrwork, armpl_int_t *info,
              ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed using the matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, as indicated by the logical array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. The eigenvector corresponding to the j-th eigenvalue is computed if SELECT(j) = .TRUE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). The upper triangular matrix T. T is modified, but restored on exit.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input and output parameter.

VL is COMPLEX

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1, and if SIDE = 'L' or 'B', LDVL >= N.

VR Input and output parameter.

VR is COMPLEX

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of array WORK. LWORK >= max(1,2*N). For optimum performance, LWORK >= N + 2*N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (LRWORK) .

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. LRWORK >= max(1, N).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dtrevc3*, *strevc3* and *ztrevc3*.

4.16.29 ctrtrs

ctrtrs solves a triangular system of the form

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine ctrtrs(UPLO, TRANS, DIAG, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ctrtrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *dtrtrs*, *strtrs* and *ztrtrs*. It also exists with a native C interface as *LAPACKE_ctrtrs*.

4.16.30 dcabs1

dcabs1 computes |Re(.)| + |Im(.)| of a double complex number

Syntax

Fortran specification:

```
use armpl_library

double precision function dcabs1(Z)
```

C specification:

```
#include "armpl.h"

double dcabs1_(const armpl_doublecomplex_t *z);
```

Parameters

Z Input parameter.

Z is COMPLEX*16

Related Information

For this routine in other precisions, please see *scabs1*.

4.16.31 dgetsls

dgetsls solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, using a tall skinny

The following options are provided:

* If TRANS = 'N' and m >= n: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize || B - A*X ||.

* If TRANS = 'N' and m < n: find the minimum norm solution of an underdetermined system A * X = B.

* If TRANS = 'T' and m >= n: find the minimum norm solution of an undetermined system A^T * X = B.

* If TRANS = 'T' and m < n: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize || B - A^T * X ||.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Syntax

Fortran specification:

```
use armpl_library

subroutine dgetsls(TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dgetsls_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *nrhs, double *a, const armpl_int_t *lda,
              double *b, const armpl_int_t *ldb, double *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': the linear system involves A; = 'T': the linear system involves A^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >=0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A is overwritten by details of its QR or LQ factorization as returned by DGEQR or DGELQ.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'T'. On exit, if INFO = 0, B is overwritten by the solution vectors, stored columnwise: if TRANS = 'N' and m >= n, rows 1 to n of B contain the least squares solution vectors. if TRANS = 'N' and m < n, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'T' and m >= n, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'T' and m < n, rows 1 to M of B contain the least squares solution vectors.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= MAX(1, M, N).

WORK Output parameter.

(workspace) DOUBLE PRECISION

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *cgetsls*, *sgetsls* and *zgetsls*. It also exists with a native C interface as *LAPACKE_dgetsls*.

4.16.32 dlasyf_rk

DLASYF_RK computes a partial factorization of a real symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L',

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

DLASYF_RK is an auxiliary routine called by DSYTRF_RK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine dlasyf_rk(UPLO, N, NB, KB, A, LDA, E, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void dlasyf_rk_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
                armpl_int_t *kb, double *a, const armpl_int_t *lda, double *e,
                armpl_int_t *ipiv, double *w, const armpl_int_t *ldw,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,N-KB+1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,N-KB+1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,N-KB+1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *clasyf_rk*, *slasyf_rk* and *zlasyf_rk*.

4.16.33 dsb2st_kernels

DSB2ST_KERNELS is an internal routine used by the DSYTRD_SB2ST subroutine.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsb2st_kernels(UPLO, WANTZ, TTYPE, ST, ED, SWEEP, N, NB, IB, A,
                          LDA, V, TAU, LDVT, WORK)
```

C specification:

```
#include "armpl.h"

void dsb2st_kernels_(const char *uplo, const armpl_int_t *wantz,
                     const armpl_int_t *ttype, const armpl_int_t *st,
                     const armpl_int_t *ed, const armpl_int_t *sweep,
                     const armpl_int_t *n, const armpl_int_t *nb,
                     const armpl_int_t *ib, double *a, const armpl_int_t *lda,
                     double *v, double *tau, const armpl_int_t *ldvt,
                     const double *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

WANTZ Input parameter.

WANTZ is LOGICAL which indicate if Eigenvalue are requested or both

Eigenvalue/Eigenvectors.

TTYPE Input parameter.

TTYPE is INTEGER

ST Input parameter.

ST is INTEGER

internal parameter for indices.

ED Input parameter.

ED is INTEGER

internal parameter for indices.

SWEEP Input parameter.

SWEEP is INTEGER

internal parameter for indices.

N Input parameter.

N is INTEGER. The order of the matrix A.

NB Input parameter.

NB is INTEGER. The size of the band.

IB Input parameter.

IB is INTEGER.

A Input and output parameter.

A is DOUBLE PRECISION array. A pointer to the matrix A.

LDA Input parameter.

LDA is INTEGER. The leading dimension of the matrix A.

V Output parameter.

V is DOUBLE PRECISION

V is an array, dimension 2*n if eigenvalues only are. requested or to be queried for vectors.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (2*n).. The scalar factors of the Householder reflectors are stored in this array.

LDVT Input parameter.

LDVT is INTEGER.

WORK Input parameter.

WORK is DOUBLE PRECISION array. Workspace of size nb.

Related Information

For this routine in other precisions, please see *ssb2st_kernels*.

4.16.34 dsbev_2stage

DSBEV_2STAGE computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A using the 2stage technique for the reduction to tridiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbev_2stage(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK,
                        INFO)
```

C specification:

```
#include "armpl.h"

void dsbev_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                   const armpl_int_t *kd, double *ab, const armpl_int_t *ldab,
                   double *w, double *z, const armpl_int_t *ldz, double *work,
                   const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension LWORK. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS + N where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *ssbev_2stage*. It also exists with a native C interface as *LAPACKE_dsbev_2stage*.

4.16.35 dsbevd_2stage

DSBEVD_2STAGE computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbevd_2stage(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK,
                         IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsbevd_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                    const armpl_int_t *kd, double *ab,
                    const armpl_int_t *ldab, double *w, double *z,
                    const armpl_int_t *ldz, double *work,
                    const armpl_int_t *lwork, armpl_int_t *iwork,
                    const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension LWORK. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS + N where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 2, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *ssbevd_2stage*. It also exists with a native C interface as *LAPACKE_dsbevd_2stage*.

4.16.36 dsbevx_2stage

DSBEVX_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsbevx_2stage(JOBZ, RANGE, UPLO, N, KD, AB, LDAB, Q, LDQ, VL, VU,
                         IL, IU, ABSTOL, M, W, Z, LDZ, WORK, LWORK, IWORK,
                         IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void dsbevx_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, const armpl_int_t *kd, double *ab,
                    const armpl_int_t *ldab, double *q,
                    const armpl_int_t *ldq, const double *vl,
                    const double *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const double *abstol,
                    armpl_int_t *m, double *w, double *z,
                    const armpl_int_t *ldz, double *work,
                    const armpl_int_t *lwork, armpl_int_t *iwork,
                    armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

Q Output parameter.

Q is DOUBLE PRECISION

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the N-by-N orthogonal matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AB to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, 7*N, dimension) where dimension = (2KD+1)* N + KD*NTHREADS + 2*N where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

4.16.37 dsyconvf

If parameter WAY = 'C': DSYCONVF converts the factorization output format used in DSYTRF provided on entry in parameter A into the factorization output format used in DSYTRF_RK (or DSYTRF_BK) that is stored on exit in parameters A and E. It also coverts in place details of the intechanges stored in IPIV from the format used in DSYTRF into the format used in DSYTRF_RK (or DSYTRF_BK).

If parameter WAY = 'R': DSYCONVF performs the conversion in reverse direction, i.e. converts the factorization output format used in DSYTRF_RK (or DSYTRF_BK) provided on entry in parameters A and E into the factorization output format used in DSYTRF that is stored on exit in parameter A. It also coverts in place details of the intechanges stored in IPIV from the format used in DSYTRF_RK (or DSYTRF_BK) into the format used in DSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyconvf(UPLO, WAY, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dsyconvf_(const char *uplo, const char *way, const armpl_int_t *n,
               double *a, const armpl_int_t *lda, double *e,
               armpl_int_t *ipiv, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix A. = 'U': Upper triangular = 'L': Lower triangular

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). 1) If WAY ='C':

On entry, contains factorization details in format used in DSYTRF: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

On exit, contains factorization details in format used in DSYTRF_RK or DSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

2) If WAY = 'R':

On entry, contains factorization details in format used in DSYTRF_RK or DSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, contains factorization details in format used in DSYTRF: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). 1) If WAY ='C':

On entry, just a workspace.

On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

2) If WAY = 'R':

On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

On exit, is not changed

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

1) If WAY ='C': On entry, details of the interchanges and the block structure of D in the format used in DSYTRF. On exit, details of the interchanges and the block structure of D in the format used in DSYTRF_RK (or DSYTRF_BK).

1) If WAY ='R': On entry, details of the interchanges and the block structure of D in the format used in DSYTRF_RK (or DSYTRF_BK). On exit, details of the interchanges and the block structure of D in the format used in DSYTRF.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyconvf*, *ssyconvf* and *zsyconvf*.

4.16.38 dsyconvf_rook

If parameter WAY = 'C': DSYCONVF_ROOK converts the factorization output format used in DSYTRF_ROOK provided on entry in parameter A into the factorization output format used in DSYTRF_RK (or DSYTRF_BK) that is stored on exit in parameters A and E. IPIV format for DSYTRF_ROOK and DSYTRF_RK (or DSYTRF_BK) is the same and is not converted.

If parameter WAY = 'R': DSYCONVF_ROOK performs the conversion in reverse direction, i.e. converts the factorization output format used in DSYTRF_RK (or DSYTRF_BK) provided on entry in parameters A and E into the factorization output format used in DSYTRF_ROOK that is stored on exit in parameter A. IPIV format for DSYTRF_ROOK and DSYTRF_RK (or DSYTRF_BK) is the same and is not converted.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyconvf_rook(UPLO, WAY, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dsyconvf_rook_(const char *uplo, const char *way, const armpl_int_t *n,
                    double *a, const armpl_int_t *lda, double *e,
                    const armpl_int_t *ipiv, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix A. = 'U': Upper triangular = 'L': Lower triangular

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). 1) If WAY ='C':

On entry, contains factorization details in format used in DSYTRF_ROOK: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

On exit, contains factorization details in format used in DSYTRF_RK or DSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

2) If WAY = 'R':

On entry, contains factorization details in format used in DSYTRF_RK or DSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, contains factorization details in format used in DSYTRF_ROOK: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input and output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). 1) If WAY ='C':

On entry, just a workspace.

On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

2) If WAY = 'R':

On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

On exit, is not changed

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

On entry, details of the interchanges and the block structure of D as determined: 1) by DSYTRF_ROOK, if WAY ='C'; 2) by DSYTRF_RK (or DSYTRF_BK), if WAY ='R'. The IPIV format is the same for all these routines.

On exit, is not changed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyconvf_rook*, *ssyconvf_rook* and *zsyconvf_rook*.

4.16.39 dsyev_2stage

DSYEV_2STAGE computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A using the 2stage technique for the reduction to tridiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyev_2stage(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsyev_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                   double *a, const armpl_int_t *lda, double *w, double *work,
                   const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading

N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension LWORK. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + 2*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 2*N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *ssyev_2stage*. It also exists with a native C interface as *LAPACKE_dsyev_2stage*.

4.16.40 dsyevd_2stage

DSYEVD_2STAGE computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyevd_2stage(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK, LIWORK,
                         INFO)
```

C specification:

```
#include "armpl.h"

void dsyevd_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                    double *a, const armpl_int_t *lda, double *w,
                    double *work, const armpl_int_t *lwork,
                    armpl_int_t *iwork, const armpl_int_t *liwork,
                    armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array,. dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N +

2*N+1 = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 2*N+1 where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *ssyevd_2stage*. It also exists with a native C interface as *LAPACKE_dsyevd_2stage*.

4.16.41 dsyevr_2stage

DSYEVR_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

DSYEVR_2STAGE first reduces the matrix A to tridiagonal form T with a call to DSYTRD. Then, whenever possible, DSYEVR_2STAGE calls DSTEMR to compute the eigenspectrum using Relatively Robust Representations. DSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
    define all the wanted eigenvalues to high relative accuracy.
    This means that small relative changes in the entries of D and L
    cause only small relative changes in the eigenvalues and
    eigenvectors. The standard (unfactored) representation of the
    tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
    If the eigenvectors are desired, the algorithm attains full
```

(continues on next page)

(continued from previous page)

```
    accuracy of the computed eigenvalues only right before
    the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
    shift close to the cluster, find a new factorization, and refine
    the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
    the corresponding eigenvector by forming a rank revealing twisted
    factorization. Go back to (c) for any clusters that remain.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see DSTEMR's documentation and: - Inderjit S. Dhillon and Beresford N. Parlett: "Multiple representations

```

Note 1 : DSYEVR_2STAGE calls DSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. DSYEVR_2STAGE calls DSTEBZ and SSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of DSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyevr_2stage(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL,
                         M, W, Z, LDZ, ISUPPZ, WORK, LWORK, IWORK, LIWORK,
                         INFO)
```

C specification:

```
#include "armpl.h"

void dsyevr_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, double *a, const armpl_int_t *lda,
                    const double *vl, const double *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const double *abstol,
                    armpl_int_t *m, double *w, double *z,
                    const armpl_int_t *ldz, armpl_int_t *isuppz, double *work,
                    const armpl_int_t *lwork, armpl_int_t *iwork,
                    const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found. For RANGE = 'V' or 'I' and IU - IL < N - 1, DSTEBZ and DSTEIN are called

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used. Supplying N columns is always safe.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is an output of DSTEMR (tridiagonal matrix). The support of the eigenvectors of A is typically 1:N because of the orthogonal transformations applied by DORMTR. Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, 26*N, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + 5*N = N*KD +

N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 5*N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

Related Information

For this routine in other precisions, please see *ssyevr_2stage*. It also exists with a native C interface as *LAPACKE_dsyevr_2stage*.

4.16.42 dsyevx_2stage

DSYEVX_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsyevx_2stage(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL,
                         M, W, Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void dsyevx_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, double *a, const armpl_int_t *lda,
                    const double *vl, const double *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const double *abstol,
                    armpl_int_t *m, double *w, double *z,
                    const armpl_int_t *ldz, double *work,
                    const armpl_int_t *lwork, armpl_int_t *iwork,
                    armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is DOUBLE PRECISION

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, 8*N, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + 3*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 3*N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *ssyevx_2stage*. It also exists with a native C interface as *LAPACKE_dsyevx_2stage*.

4.16.43 dsygv_2stage

DSYGV_2STAGE computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. This routine use the 2stage technique for the reduction to tridiagonal which showed higher performance on recent architecture and for large sizes N>2000.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsygv_2stage(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK,
                        INFO)
```

C specification:

```
#include "armpl.h"

void dsygv_2stage_(const armpl_int_t *itype, const char *jobz,
                   const char *uplo, const armpl_int_t *n, double *a,
                   const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
                   double *w, double *work, const armpl_int_t *lwork,
                   armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B*Z = I; if ITYPE = 3, Z^T *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, N). On entry, the symmetric positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + 2*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 2*N where

KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: DPOTRF or DSYEV returned an error code: <= N: if INFO = i, DSYEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *ssygv_2stage*. It also exists with a native C interface as *LAPACKE_dsygv_2stage*.

4.16.44 dsysv_aa_2stage

DSYSV_AA_2STAGE computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Aasen's 2-stage algorithm is used to factor A as

```
A = U * T * U**T,  if UPLO = 'U', or
A = L * T * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is symmetric and band. The matrix T is then LU-factored with partial pivoting. The factored form of A is then used to solve the system of equations A * X = B.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsysv_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                           LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsysv_aa_2stage_(const char *uplo, const armpl_int_t *n,
                      const armpl_int_t *nrhs, double *a,
                      const armpl_int_t *lda, double *tb,
                      const armpl_int_t *ltb, armpl_int_t *ipiv,
                      armpl_int_t *ipiv2, double *b, const armpl_int_t *ldb,
```

(continues on next page)

(continued from previous page)

```
                        double *work, const armpl_int_t *lwork,
                        armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is DOUBLE PRECISION

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is DOUBLE PRECISION workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

For this routine in other precisions, please see *csysv_aa_2stage*, *ssysv_aa_2stage* and *zsysv_aa_2stage*. It also exists with a native C interface as *LAPACKE_dsysv_aa_2stage*.

4.16.45 dsytf2_rk

DSYTF2_RK computes the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytf2_rk(UPLO, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void dsytf2_rk_(const char *uplo, const armpl_int_t *n, double *a,
                const armpl_int_t *lda, double *e, armpl_int_t *ipiv,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

4.16.46 dsytrd_2stage

DSYTRD_2STAGE reduces a real symmetric matrix A to real symmetric tridiagonal form T by a orthogonal similarity transformation: $Q1^T$ $Q2^T$ * A * Q2 * Q1 = T.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrd_2stage(VECT, UPLO, N, A, LDA, D, E, TAU, HOUS2, LHOUS2,
                         WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrd_2stage_(const char *vect, const char *uplo, const armpl_int_t *n,
                    double *a, const armpl_int_t *lda, double *d, double *e,
                    double *tau, double *hous2, const armpl_int_t *lhous2,
                    double *work, const armpl_int_t *lwork, armpl_int_t *info,
                    ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': No need for the Housholder representation, in particular for the second stage (Band to tridiagonal) and thus LHOUS2 is of size max(1, 4*N); = 'V': the Householder representation is needed to either generate Q1 Q2 or to apply Q1 Q2, then LHOUS2 is to be queried and computed. (NOT AVAILABLE IN THIS RELEASE).

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the band superdiagonal of A are overwritten by the corresponding elements of the internal band-diagonal matrix AB, and the elements above the KD superdiagonal, with the array TAU, represent the orthogonal matrix Q1 as a product of elementary reflectors; if UPLO = 'L', the diagonal and band subdiagonal of A are over- written by the corresponding elements of the internal band-diagonal matrix AB, and the elements below the KD subdiagonal, with the array TAU, represent the orthogonal matrix Q1 as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-KD). The scalar factors of the elementary reflectors of the first stage (see Further Details).

HOUS2 Output parameter.

HOUS2 is DOUBLE PRECISION

HOUS2 is an array, dimension LHOUS2, that. store the Householder representation of the stage2 band to tridiagonal.

LHOUS2 Input parameter.

LHOUS2 is INTEGER

The dimension of the array HOUS2. LHOUS2 = MAX(1, dimension) If LWORK = -1, or LHOUS2=-1, then a query is assumed; the routine only calculates the optimal size of the HOUS2 array, returns this value as the first entry of the HOUS2 array, and no error message related to LHOUS2 is issued by XERBLA. LHOUS2 = MAX(1, dimension) where dimension = 4* N if VECT='N' not available now if VECT='H'

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK = MAX(1, dimension) If LWORK = -1, or LHOUS2=-1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ssytrd_2stage*.

4.16.47 dsytrd_sy2sb

DSYTRD_SY2SB reduces a real symmetric matrix A to real symmetric band-diagonal form AB by a orthogonal similarity transformation: Q^T * A * Q = AB.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrd_sy2sb(UPLO, N, KD, A, LDA, AB, LDAB, TAU, WORK, LWORK,
                        INFO)
```

C specification:

```
#include "armpl.h"

void dsytrd_sy2sb_(const char *uplo, const armpl_int_t *n,
                   const armpl_int_t *kd, double *a, const armpl_int_t *lda,
                   double *ab, const armpl_int_t *ldab, double *tau,
                   double *work, const armpl_int_t *lwork, armpl_int_t *info,
                   ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the reduced matrix if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0. The reduced matrix is stored in the array AB.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AB Output parameter.

AB is DOUBLE PRECISION

AB is an array, dimension (LDAB, N). On exit, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

TAU Output parameter.

TAU is DOUBLE PRECISION

TAU is an array, dimension (N-KD). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (LWORK). On exit, if INFO = 0, or if LWORK=-1, WORK(1) returns the size of LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK which should be calculated by a workspace query. LWORK = MAX(1, LWORK_QUERY) If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA. LWORK_QUERY = N* KD + N*max(KD,FACTOPTNB) + 2*KD*KD where FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice otherwise putting LWORK=-1 will provide the size of WORK.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ssytrd_sy2sb*.

4.16.48 dsytrf_aa_2stage

DSYTRF_AA_2STAGE computes the factorization of a real symmetric matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a symmetric band matrix with the bandwidth of NB (NB is internally selected and stored in TB(1), and T is LU factorized with partial pivoting).

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrf_aa_2stage(UPLO, N, A, LDA, TB, LTB, IPIV, IPIV2, WORK,
                            LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrf_aa_2stage_(const char *uplo, const armpl_int_t *n, double *a,
                       const armpl_int_t *lda, double *tb,
                       const armpl_int_t *ltb, armpl_int_t *ipiv,
                       armpl_int_t *ipiv2, double *work,
                       const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is DOUBLE PRECISION

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

WORK Output parameter.

WORK is DOUBLE PRECISION workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *csytrf_aa_2stage*, *ssytrf_aa_2stage* and *zsytrf_aa_2stage*. It also exists with a native C interface as *LAPACKE_dsytrf_aa_2stage*.

4.16.49 dsytri_3x

DSYTRI_3X computes the inverse of a real symmetric indefinite matrix A using the factorization computed by DSYTRF_RK or DSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytri_3x(UPLO, N, A, LDA, E, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void dsytri_3x_(const char *uplo, const armpl_int_t *n, double *a,
                const armpl_int_t *lda, const double *e,
                const armpl_int_t *ipiv, double *work, const armpl_int_t *nb,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by DSYTRF_RK and DSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal

matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the symmetric inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is DOUBLE PRECISION

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by DSYTRF_RK or DSYTRF_BK.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (N+NB+1,NB+3). .

NB Input parameter.

NB is INTEGER

Block size.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri_3x*, *ssytri_3x* and *zsytri_3x*.

4.16.50 dsytrs_aa_2stage

DSYTRS_AA_2STAGE solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*T*U^T or A = L*T*L^T computed by DSYTRF_AA_2STAGE.

Syntax

Fortran specification:

```
use armpl_library

subroutine dsytrs_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                            LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dsytrs_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       const armpl_int_t *nrhs, const double *a,
                       const armpl_int_t *lda, double *tb,
                       const armpl_int_t *ltb, const armpl_int_t *ipiv,
                       const armpl_int_t *ipiv2, double *b,
                       const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). Details of factors computed by DSYTRF_AA_2STAGE.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is DOUBLE PRECISION

TB is an array, dimension (LTB). Details of factors computed by DSYTRF_AA_2STAGE.

LTB Input parameter.

The size of the array TB. LTB >= 4*N.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by DSYTRF_AA_2STAGE.

IPIV2 Input parameter.

IPIV2 is INTEGER array, dimension (N)

Details of the interchanges as computed by DSYTRF_AA_2STAGE.

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_aa_2stage*, *ssytrs_aa_2stage* and *zsytrs_aa_2stage*. It also exists with a native C interface as *LAPACKE_dsytrs_aa_2stage*.

4.16.51 dtrevc3

dtrevc3 computes some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T. Matrices of this type are produced by the Schur factorization of a real general matrix: A = Q*T*Q^T , as computed by DHSEQR.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
T*x = w*x,      (y**H)*T = w*(y**H)
```

where y^H denotes the conjugate transpose of y. The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of T.

This routine returns the matrices X and/or Y of right and left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input matrix. If Q is the orthogonal factor that reduces a matrix A to Schur form T, then Q*X and Q*Y are the matrices of right and left eigenvectors of A.

This uses a Level 3 BLAS version of the back transformation.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrevc3(SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, MM, M,
                   WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void dtrevc3_(const char *side, const char *howmny, armpl_int_t *select,
              const armpl_int_t *n, const double *t, const armpl_int_t *ldt,
              double *vl, const armpl_int_t *ldvl, double *vr,
              const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
              double *work, const armpl_int_t *lwork, armpl_int_t *info,
              ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed by the matrices in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, as indicated by the logical array SELECT.

SELECT Input and output parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If w(j) is a real eigenvalue, the corresponding real eigenvector is computed if SELECT(j) is .TRUE.. If w(j) and w(j+1) are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either SELECT(j) or SELECT(j+1) is .TRUE., and on exit SELECT(j) is set to .TRUE. and SELECT(j+1) is set to .FALSE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input parameter.

T is DOUBLE PRECISION

T is an array, dimension (LDT, N). The upper quasi-triangular matrix T in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input and output parameter.

VL is DOUBLE PRECISION

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by DHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1, and if SIDE = 'L' or 'B', LDVL >= N.

VR Input and output parameter.

VR is DOUBLE PRECISION

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by DHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively

in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK Output parameter.

WORK is DOUBLE PRECISION

WORK is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of array WORK. LWORK >= max(1,3*N). For optimum performance, LWORK >= N + 2*N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrevc3*, *strevc3* and *ztrevc3*.

4.16.52 dtrtrs

dtrtrs solves a triangular system of the form

```
A * X = B  or  A**T * X = B,
```

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine dtrtrs(UPLO, TRANS, DIAG, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void dtrtrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs, const double *a,
             const armpl_int_t *lda, double *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is DOUBLE PRECISION

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *ctrtrs*, *strtrs* and *ztrtrs*. It also exists with a native C interface as *LAPACKE_dtrtrs*.

4.16.53 icmax1

icmax1 finds the index of the first vector element of maximum absolute value.

Based on ICAMAX from Level 1 BLAS. The change is to use the 'genuine' absolute value.

Syntax

Fortran specification:

```
use armpl_library

integer function icmax1(N, CX, INCX)
```

C specification:

```
#include "armpl.h"

armpl_int_t icmax1_(const armpl_int_t *n, const armpl_singlecomplex_t *cx,
                    const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements in the vector CX.

CX Input parameter.

CX is COMPLEX

CX is an array, dimension (N). The vector CX. The ICMAX1 function returns the index of its first element of maximum absolute value.

INCX Input parameter.

INCX is INTEGER

The spacing between successive values of CX. INCX >= 1.

Related Information

4.16.54 ilaclc

`ilaclc` scans A for its last non-zero column.

Syntax

Fortran specification:

```
use armpl_library

integer function ilaclc(M, N, A, LDA)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilaclc_(const armpl_int_t *m, const armpl_int_t *n,
                    const armpl_singlecomplex_t *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`.

A Input parameter.

`A` is `COMPLEX`

`A` is an array, dimension (`LDA`, `N`). The m by n matrix `A`.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

Related Information

4.16.55 ilaclr

`ilaclr` scans A for its last non-zero row.

Syntax

Fortran specification:

```
use armpl_library

integer function ilaclr(M, N, A, LDA)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilaclr_(const armpl_int_t *m, const armpl_int_t *n,
                    const armpl_singlecomplex_t *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A.

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The m by n matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

4.16.56 iladlc

iladlc scans A for its last non-zero column.

Syntax

Fortran specification:

```
use armpl_library

integer function iladlc(M, N, A, LDA)
```

C specification:

```
#include "armpl.h"

armpl_int_t iladlc_(const armpl_int_t *m, const armpl_int_t *n,
                    const double *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A.

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The m by n matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

4.16.57 iladlr

iladlr scans A for its last non-zero row.

Syntax

Fortran specification:

```
use armpl_library

integer function iladlr(M, N, A, LDA)
```

C specification:

```
#include "armpl.h"

armpl_int_t iladlr_(const armpl_int_t *m, const armpl_int_t *n,
                    const double *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A.

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input parameter.

A is DOUBLE PRECISION

A is an array, dimension (LDA, N). The m by n matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

4.16.58 ilaenv2stage

ILAENV2STAGE is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See ISPEC for a description of the parameters. It sets problem and machine dependent parameters useful for *_2STAGE and related subroutines.

ILAENV2STAGE returns an INTEGER if ILAENV2STAGE >= 0: ILAENV2STAGE returns the value of the parameter if ILAENV2STAGE < 0: if ILAENV2STAGE = -k, the k-th argument had an This version provides a set of parameters which should give good, but not optimal, performance on many of the currently available computers for the 2-stage solvers. Users are encouraged to modify this subroutine to set the tuning parameters for their particular machine using the option and problem size information in the arguments.

This routine will not function correctly if it is converted to all lower case. Converting it to all upper case is allowed.

Syntax

Fortran specification:

```
use armpl_library

integer function ilaenv2stage(ISPEC, NAME, OPTS, N1, N2, N3, N4)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilaenv2stage_(const armpl_int_t *ispec, const char *name,
                          const char *opts, const armpl_int_t *n1,
                          const armpl_int_t *n2, const armpl_int_t *n3,
                          const armpl_int_t *n4, ... );
```

Parameters

ISPEC Input parameter.

ISPEC is INTEGER

Specifies the parameter to be returned as the value of ILAENV2STAGE. = 1: the optimal blocksize nb for the reduction to BAND

= 2: the optimal blocksize ib for the eigenvectors singular vectors update routine

= 3: The length of the array that store the Housholder representation for the second stage Band to Tridiagonal or Bidiagonal

= 4: The workspace needed for the routine in input.

= 5: For future release.

NAME Input parameter.

NAME is CHARACTER*(*)

The name of the calling subroutine, in either upper case or lower case.

OPTS Input parameter.

OPTS is CHARACTER*(*)

The character options to the subroutine NAME, concatenated into a single character string. For example, UPLO = 'U', TRANS = 'T', and DIAG = 'N' for a triangular routine would be specified as OPTS = 'UTN'.

N1 Input parameter.

N1 is INTEGER

N2 Input parameter.

N2 is INTEGER

N3 Input parameter.

N3 is INTEGER

N4 Input parameter.

N4 is INTEGER

Problem dimensions for the subroutine NAME; these may not all be required.

Related Information

4.16.59 ilaslc

ilaslc scans A for its last non-zero column.

Syntax

Fortran specification:

```
use armpl_library

integer function ilaslc(M, N, A, LDA)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilaslc_(const armpl_int_t *m, const armpl_int_t *n,
                    const float *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A.

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The m by n matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

4.16.60 ilaslr

`ilaslr` scans A for its last non-zero row.

Syntax

Fortran specification:

```
use armpl_library

integer function ilaslr(M, N, A, LDA)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilaslr_(const armpl_int_t *m, const armpl_int_t *n,
                    const float *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`.

A Input parameter.

`A` is `REAL`

`A` is an array, dimension (`LDA`, `N`). The m by n matrix `A`.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

Related Information

4.16.61 ilazlc

`ilazlc` scans A for its last non-zero column.

Syntax

Fortran specification:

```
use armpl_library

integer function ilazlc(M, N, A, LDA)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilazlc_(const armpl_int_t *m, const armpl_int_t *n,
                    const armpl_doublecomplex_t *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A.

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The m by n matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

4.16.62 ilazlr

ilazlr scans A for its last non-zero row.

Syntax

Fortran specification:

```
use armpl_library

integer function ilazlr(M, N, A, LDA)
```

C specification:

```
#include "armpl.h"

armpl_int_t ilazlr_(const armpl_int_t *m, const armpl_int_t *n,
                    const armpl_doublecomplex_t *a, const armpl_int_t *lda);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A.

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The m by n matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

4.16.63 izmax1

izmax1 finds the index of the first vector element of maximum absolute value.

Based on IZAMAX from Level 1 BLAS. The change is to use the 'genuine' absolute value.

Syntax

Fortran specification:

```
use armpl_library

integer function izmax1(N, ZX, INCX)
```

C specification:

```
#include "armpl.h"

armpl_int_t izmax1_(const armpl_int_t *n, const armpl_doublecomplex_t *zx,
                    const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements in the vector ZX.

ZX Input parameter.

ZX is COMPLEX*16

ZX is an array, dimension (N). The vector ZX. The IZMAX1 function returns the index of its first element of maximum absolute value.

INCX Input parameter.

INCX is INTEGER

The spacing between successive values of ZX. INCX >= 1.

Related Information

4.16.64 nancheck_flag

Syntax

Fortran specification:

```
use armpl_library

int nancheck_flag
```

C specification:

```
#include "armpl.h"

int nancheck_fla
```

Parameters

Related Information

4.16.65 scabs1

`scabs1` computes |Re(.)| + |Im(.)| of a complex number

Syntax

Fortran specification:

```
use armpl_library

real function scabs1(Z)
```

C specification:

```
#include "armpl.h"

float scabs1_(const armpl_singlecomplex_t *c);
```

Parameters

`Z` Input parameter.

`Z` is `COMPLEX`

Related Information

For this routine in other precisions, please see *dcabs1*.

4.16.66 sgetsls

`sgetsls` solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, using a tall skinny

The following options are provided:

* If TRANS = 'N' and m >= n: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize || B - A*X ||.

* If TRANS = 'N' and m < n: find the minimum norm solution of an underdetermined system A * X = B.

* If TRANS = 'T' and m >= n: find the minimum norm solution of an undetermined system A^T * X = B.

* If TRANS = 'T' and m < n: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize || B - A^T * X ||.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Syntax

Fortran specification:

```
use armpl_library

subroutine sgetsls(TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void sgetsls_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *nrhs, float *a, const armpl_int_t *lda,
              float *b, const armpl_int_t *ldb, float *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': the linear system involves A; = 'T': the linear system involves A^T .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >=0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A is overwritten by details of its QR or LQ factorization as returned by SGEQR or SGELQ.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'T'. On exit, if INFO = 0, B is overwritten by the solution vectors, stored columnwise: if TRANS = 'N' and m >= n, rows 1 to n of B contain the least squares solution vectors. if TRANS = 'N' and m < n, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'T' and m >= n, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'T' and m < n, rows 1 to M of B contain the least squares solution vectors.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= MAX(1, M, N).

WORK Output parameter.

(workspace) REAL

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

Related Information

For this routine in other precisions, please see *cgetsls*, *dgetsls* and *zgetsls*. It also exists with a native C interface as *LAPACKE_sgetsls*.

4.16.67 slasyf_rk

SLASYF_RK computes a partial factorization of a real symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L',

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

SLASYF_RK is an auxiliary routine called by SSYTRF_RK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine slasyf_rk(UPLO, N, NB, KB, A, LDA, E, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void slasyf_rk_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
                armpl_int_t *kb, float *a, const armpl_int_t *lda, float *e,
                armpl_int_t *ipiv, float *w, const armpl_int_t *ldw,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is REAL

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,N-KB+1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,N-KB+1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,N-KB+1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

W Output parameter.

W is REAL

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

4.16.68 ssb2st_kernels

SSB2ST_KERNELS is an internal routine used by the SSYTRD_SB2ST subroutine.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssb2st_kernels(UPLO, WANTZ, TTYPE, ST, ED, SWEEP, N, NB, IB, A,
                          LDA, V, TAU, LDVT, WORK)
```

C specification:

```
#include "armpl.h"

void ssb2st_kernels_(const char *uplo, const armpl_int_t *wantz,
                     const armpl_int_t *ttype, const armpl_int_t *st,
                     const armpl_int_t *ed, const armpl_int_t *sweep,
                     const armpl_int_t *n, const armpl_int_t *nb,
                     const armpl_int_t *ib, float *a, const armpl_int_t *lda,
                     float *v, float *tau, const armpl_int_t *ldvt,
                     const float *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

WANTZ Input parameter.

WANTZ is LOGICAL which indicate if Eigenvalue are requested or both

Eigenvalue/Eigenvectors.

TTYPE Input parameter.

TTYPE is INTEGER

ST Input parameter.

ST is INTEGER

internal parameter for indices.

ED Input parameter.

ED is INTEGER

internal parameter for indices.

SWEEP Input parameter.

SWEEP is INTEGER

internal parameter for indices.

N Input parameter.

N is INTEGER. The order of the matrix A.

NB Input parameter.

NB is INTEGER. The size of the band.

IB Input parameter.

IB is INTEGER.

A Input and output parameter.

A is REAL array. A pointer to the matrix A.

LDA Input parameter.

LDA is INTEGER. The leading dimension of the matrix A.

V Output parameter.

V is REAL

V is an array, dimension 2*n if eigenvalues only are. requested or to be queried for vectors.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (2*n).. The scalar factors of the Householder reflectors are stored in this array.

LDVT Input parameter.

LDVT is INTEGER.

WORK Input parameter.

WORK is REAL array. Workspace of size nb.

n Input parameter.

The order of the matrix A.

Related Information

For this routine in other precisions, please see *dsb2st_kernels*.

4.16.69 ssbev_2stage

SSBEV_2STAGE computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A using the 2stage technique for the reduction to tridiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbev_2stage(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK,
                        INFO)
```

C specification:

```
#include "armpl.h"

void ssbev_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                   const armpl_int_t *kd, float *ab, const armpl_int_t *ldab,
                   float *w, float *z, const armpl_int_t *ldz, float *work,
                   const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension LWORK. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS + N where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dsbev_2stage*. It also exists with a native C interface as *LAPACKE_ssbev_2stage*.

4.16.70 ssbevd_2stage

SSBEVD_2STAGE computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbevd_2stage(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK,
                         IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssbevd_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                    const armpl_int_t *kd, float *ab, const armpl_int_t *ldab,
```

(continues on next page)

(continued from previous page)

```
                    float *w, float *z, const armpl_int_t *ldz, float *work,
                    const armpl_int_t *lwork, armpl_int_t *iwork,
                    const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension LWORK. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS + N where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 2, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dsbevd_2stage*. It also exists with a native C interface as *LAPACKE_ssbevd_2stage*.

4.16.71 ssbevx_2stage

SSBEVX_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssbevx_2stage(JOBZ, RANGE, UPLO, N, KD, AB, LDAB, Q, LDQ, VL, VU,
                         IL, IU, ABSTOL, M, W, Z, LDZ, WORK, LWORK, IWORK,
                         IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void ssbevx_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, const armpl_int_t *kd, float *ab,
                    const armpl_int_t *ldab, float *q, const armpl_int_t *ldq,
                    const float *vl, const float *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const float *abstol,
                    armpl_int_t *m, float *w, float *z,
                    const armpl_int_t *ldz, float *work,
                    const armpl_int_t *lwork, armpl_int_t *iwork,
                    armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

Q Output parameter.

Q is REAL

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the N-by-N orthogonal matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AB to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, 7*N, dimension) where dimension = (2KD+1)* N + KD*NTHREADS + 2*N where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *dsbevx_2stage*. It also exists with a native C interface as *LAPACKE_ssbevx_2stage*.

4.16.72 ssyconvf

If parameter WAY = 'C': SSYCONVF converts the factorization output format used in SSYTRF provided on entry in parameter A into the factorization output format used in SSYTRF_RK (or SSYTRF_BK) that is stored on exit in parameters A and E. It also coverts in place details of the intechanges stored in IPIV from the format used in SSYTRF into the format used in SSYTRF_RK (or SSYTRF_BK).

If parameter WAY = 'R': SSYCONVF performs the conversion in reverse direction, i.e. converts the factorization output format used in SSYTRF_RK (or SSYTRF_BK) provided on entry in parameters A and E into the factorization output format used in SSYTRF that is stored on exit in parameter A. It also coverts in place details of the intechanges stored in IPIV from the format used in SSYTRF_RK (or SSYTRF_BK) into the format used in SSYTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyconvf(UPLO, WAY, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void ssyconvf_(const char *uplo, const char *way, const armpl_int_t *n,
               float *a, const armpl_int_t *lda, float *e, armpl_int_t *ipiv,
               armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix A. = 'U': Upper triangular = 'L': Lower triangular

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). 1) If WAY ='C':

On entry, contains factorization details in format used in SSYTRF: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

On exit, contains factorization details in format used in SSYTRF_RK or SSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

2) If WAY = 'R':

On entry, contains factorization details in format used in SSYTRF_RK or SSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, contains factorization details in format used in SSYTRF: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input and output parameter.

E is REAL

E is an array, dimension (N). 1) If WAY ='C':

On entry, just a workspace.

On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

2) If WAY = 'R':

On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

On exit, is not changed

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

1) If WAY ='C': On entry, details of the interchanges and the block structure of D in the format used in SSYTRF. On exit, details of the interchanges and the block structure of D in the format used in SSYTRF_RK (or SSYTRF_BK).

1) If WAY ='R': On entry, details of the interchanges and the block structure of D in the format used in SSYTRF_RK (or SSYTRF_BK). On exit, details of the interchanges and the block structure of D in the format used in SSYTRF.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyconvf*, *dsyconvf* and *zsyconvf*.

4.16.73 ssyconvf_rook

If parameter WAY = 'C': SSYCONVF_ROOK converts the factorization output format used in SSYTRF_ROOK provided on entry in parameter A into the factorization output format used in SSYTRF_RK (or SSYTRF_BK) that is stored on exit in parameters A and E. IPIV format for SSYTRF_ROOK and SSYTRF_RK (or SSYTRF_BK) is the same and is not converted.

If parameter WAY = 'R': SSYCONVF_ROOK performs the conversion in reverse direction, i.e. converts the factorization output format used in SSYTRF_RK (or SSYTRF_BK) provided on entry in parameters A and E into the factorization output format used in SSYTRF_ROOK that is stored on exit in parameter A. IPIV format for SSYTRF_ROOK and SSYTRF_RK (or SSYTRF_BK) is the same and is not converted.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyconvf_rook(UPLO, WAY, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void ssyconvf_rook_(const char *uplo, const char *way, const armpl_int_t *n,
                    float *a, const armpl_int_t *lda, float *e,
                    const armpl_int_t *ipiv, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix A. = 'U': Upper triangular = 'L': Lower triangular

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). 1) If WAY ='C':

On entry, contains factorization details in format used in SSYTRF_ROOK: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

On exit, contains factorization details in format used in SSYTRF_RK or SSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

2) If WAY = 'R':

On entry, contains factorization details in format used in SSYTRF_RK or SSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, contains factorization details in format used in SSYTRF_ROOK: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input and output parameter.

E is REAL

E is an array, dimension (N). 1) If WAY ='C':

On entry, just a workspace.

On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

2) If WAY = 'R':

On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

On exit, is not changed

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

On entry, details of the interchanges and the block structure of D as determined: 1) by SSYTRF_ROOK, if WAY ='C'; 2) by SSYTRF_RK (or SSYTRF_BK), if WAY ='R'. The IPIV format is the same for all these routines.

On exit, is not changed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

4.16.74 ssyev_2stage

SSYEV_2STAGE computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A using the 2stage technique for the reduction to tridiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyev_2stage(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssyev_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                   float *a, const armpl_int_t *lda, float *w, float *work,
                   const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension LWORK. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + 2*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 2*N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *dsyev_2stage*. It also exists with a native C interface as *LAPACKE_ssyev_2stage*.

4.16.75 ssyevd_2stage

SSYEVD_2STAGE computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyevd_2stage(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK, LIWORK,
                         INFO)
```

C specification:

```
#include "armpl.h"

void ssyevd_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                    float *a, const armpl_int_t *lda, float *w, float *work,
                    const armpl_int_t *lwork, armpl_int_t *iwork,
                    const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is REAL

WORK is an array,. dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + 2*N+1 = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 2*N+1 where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6* N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK and IWORK arrays, returns these values as the first entries of the WORK and IWORK arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *dsyevd_2stage*. It also exists with a native C interface as *LAPACKE_ssyevd_2stage*.

4.16.76 ssyevr_2stage

SSYEVR_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

SSYEVR_2STAGE first reduces the matrix A to tridiagonal form T with a call to SSYTRD. Then, whenever possible, SSYEVR_2STAGE calls SSTEMR to compute the eigenspectrum using Relatively Robust Representations. SSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
    define all the wanted eigenvalues to high relative accuracy.
    This means that small relative changes in the entries of D and L
    cause only small relative changes in the eigenvalues and
    eigenvectors. The standard (unfactored) representation of the
    tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
    If the eigenvectors are desired, the algorithm attains full
    accuracy of the computed eigenvalues only right before
    the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
    shift close to the cluster, find a new factorization, and refine
    the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
    the corresponding eigenvector by forming a rank revealing twisted
    factorization. Go back to (c) for any clusters that remain.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see SSTEMR's documentation and: - Inderjit S. Dhillon and Beresford N. Parlett: "Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

- Inderjit Dhillon and Beresford Parlett: "Orthogonal Eigenvectors and

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

- Inderjit Dhillon: "A new O(n^2) algorithm for the symmetric

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Note 1 : SSYEVR_2STAGE calls SSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. SSYEVR_2STAGE calls SSTEBZ and SSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of SSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyevr_2stage(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL,
                         M, W, Z, LDZ, ISUPPZ, WORK, LWORK, IWORK, LIWORK,
                         INFO)
```

C specification:

```
#include "armpl.h"

void ssyevr_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, float *a, const armpl_int_t *lda,
                    const float *vl, const float *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const float *abstol,
                    armpl_int_t *m, float *w, float *z,
                    const armpl_int_t *ldz, armpl_int_t *isuppz, float *work,
                    const armpl_int_t *lwork, armpl_int_t *iwork,
                    const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found. For RANGE = 'V' or 'I' and IU - IL < N - 1, SSTEBZ and SSTEIN are called

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used. Supplying N columns is always safe.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is an output of SSTEMR (tridiagonal matrix). The support of the eigenvectors of A is typically 1:N because of the orthogonal transformations applied by SORMTR. Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, 26*N, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + 5*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 5*N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

Related Information

4.16.77 ssyevx_2stage

SSYEVX_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssyevx_2stage(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL,
                         M, W, Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void ssyevx_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, float *a, const armpl_int_t *lda,
                    const float *vl, const float *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const float *abstol,
                    armpl_int_t *m, float *w, float *z,
                    const armpl_int_t *ldz, float *work,
                    const armpl_int_t *lwork, armpl_int_t *iwork,
                    armpl_int_t *ifail, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is REAL

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is REAL

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is REAL

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is REAL

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is REAL

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column

of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, 8*N, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + 3*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 3*N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *dsyevx_2stage*. It also exists with a native C interface as *LAPACKE_ssyevx_2stage*.

4.16.78 ssygv_2stage

SSYGV_2STAGE computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. This routine use the 2stage technique for the reduction to tridiagonal which showed higher performance on recent architecture and for large sizes N>2000.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssygv_2stage(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK,
                        INFO)
```

C specification:

```
#include "armpl.h"

void ssygv_2stage_(const armpl_int_t *itype, const char *jobz,
                   const char *uplo, const armpl_int_t *n, float *a,
                   const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
                   float *w, float *work, const armpl_int_t *lwork,
                   armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^T *B*Z = I; if ITYPE = 3, Z^T *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, the symmetric positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^T *U or B = L*L^T .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + 2*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + 2*N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: SPOTRF or SSYEV returned an error code: <= N: if INFO = i, SSYEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *dsygv_2stage*. It also exists with a native C interface as *LAPACKE_ssygv_2stage*.

4.16.79 ssysv_aa_2stage

SSYSV_AA_2STAGE computes the solution to a real system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Aasen's 2-stage algorithm is used to factor A as

```
A = U * T * U**T,  if UPLO = 'U', or
A = L * T * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is symmetric and band. The matrix T is then LU-factored with partial pivoting. The factored form of A is then used to solve the system of equations A * X = B.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssysv_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                           LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssysv_aa_2stage_(const char *uplo, const armpl_int_t *n,
                      const armpl_int_t *nrhs, float *a,
                      const armpl_int_t *lda, float *tb,
                      const armpl_int_t *ltb, armpl_int_t *ipiv,
                      armpl_int_t *ipiv2, float *b, const armpl_int_t *ldb,
                      float *work, const armpl_int_t *lwork,
                      armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is REAL

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is REAL workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *csysv_aa_2stage*, *dsysv_aa_2stage* and *zsysv_aa_2stage*. It also exists with a native C interface as *LAPACKE_ssysv_aa_2stage*.

4.16.80 ssytf2_rk

SSYTF2_RK computes the factorization of a real symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytf2_rk(UPLO, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void ssytf2_rk_(const char *uplo, const armpl_int_t *n, float *a,
                const armpl_int_t *lda, float *e, armpl_int_t *ipiv,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is REAL

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

4.16.81 ssytrd_2stage

SSYTRD_2STAGE reduces a real symmetric matrix A to real symmetric tridiagonal form T by a orthogonal similarity transformation: $Q1^T$ $Q2^T$ * A * Q2 * Q1 = T.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrd_2stage(VECT, UPLO, N, A, LDA, D, E, TAU, HOUS2, LHOUS2,
                         WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrd_2stage_(const char *vect, const char *uplo, const armpl_int_t *n,
                    float *a, const armpl_int_t *lda, float *d, float *e,
                    float *tau, float *hous2, const armpl_int_t *lhous2,
                    float *work, const armpl_int_t *lwork, armpl_int_t *info,
                    ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': No need for the Housholder representation, in particular for the second stage (Band to tridiagonal) and thus LHOUS2 is of size max(1, 4*N); = 'V': the Householder representation is needed to either generate Q1 Q2 or to apply Q1 Q2, then LHOUS2 is to be queried and computed. (NOT AVAILABLE IN THIS RELEASE).

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the band superdiagonal of A are overwritten by the corresponding elements of the internal band-diagonal matrix AB, and the elements above the KD superdiagonal, with the array TAU, represent the orthogonal matrix Q1 as a product of elementary reflectors; if UPLO = 'L', the diagonal and band subdiagonal of A are

over- written by the corresponding elements of the internal band-diagonal matrix AB, and the elements below the KD subdiagonal, with the array TAU, represent the orthogonal matrix Q1 as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (N-KD). The scalar factors of the elementary reflectors of the first stage (see Further Details).

HOUS2 Output parameter.

HOUS2 is REAL

HOUS2 is an array, dimension LHOUS2, that. store the Householder representation of the stage2 band to tridiagonal.

LHOUS2 Input parameter.

LHOUS2 is INTEGER

The dimension of the array HOUS2. LHOUS2 = MAX(1, dimension) If LWORK = -1, or LHOUS2=-1, then a query is assumed; the routine only calculates the optimal size of the HOUS2 array, returns this value as the first entry of the HOUS2 array, and no error message related to LHOUS2 is issued by XERBLA. LHOUS2 = MAX(1, dimension) where dimension = 4* N if VECT='N' not available now if VECT='H'

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK = MAX(1, dimension) If LWORK = -1, or LHOUS2=-1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsytrd_2stage*.

4.16.82 ssytrd_sy2sb

SSYTRD_SY2SB reduces a real symmetric matrix A to real symmetric band-diagonal form AB by a orthogonal similarity transformation: Q^T * A * Q = AB.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrd_sy2sb(UPLO, N, KD, A, LDA, AB, LDAB, TAU, WORK, LWORK,
                        INFO)
```

C specification:

```
#include "armpl.h"

void ssytrd_sy2sb_(const char *uplo, const armpl_int_t *n,
                   const armpl_int_t *kd, float *a, const armpl_int_t *lda,
                   float *ab, const armpl_int_t *ldab, float *tau,
                   float *work, const armpl_int_t *lwork, armpl_int_t *info,
                   ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the reduced matrix if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0. The reduced matrix is stored in the array AB.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the

first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AB Output parameter.

AB is REAL

AB is an array, dimension (LDAB, N). On exit, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

TAU Output parameter.

TAU is REAL

TAU is an array, dimension (N-KD). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK). On exit, if INFO = 0, or if LWORK=-1, WORK(1) returns the size of LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK which should be calculated by a workspace query. LWORK = MAX(1, LWORK_QUERY) If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA. LWORK_QUERY = N* KD + N*max(KD,FACTOPTNB) + 2*KD*KD where FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice otherwise putting LWORK=-1 will provide the size of WORK.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsytrd_sy2sb*.

4.16.83 ssytrf_aa_2stage

SSYTRF_AA_2STAGE computes the factorization of a real symmetric matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a symmetric band matrix with the bandwidth of NB (NB is internally selected and stored in TB(1), and T is LU factorized with partial pivoting).

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrf_aa_2stage(UPLO, N, A, LDA, TB, LTB, IPIV, IPIV2, WORK,
                            LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrf_aa_2stage_(const char *uplo, const armpl_int_t *n, float *a,
                       const armpl_int_t *lda, float *tb,
                       const armpl_int_t *ltb, armpl_int_t *ipiv,
                       armpl_int_t *ipiv2, float *work,
                       const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is REAL

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is REAL workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *csytrf_aa_2stage*, *dsytrf_aa_2stage* and *zsytrf_aa_2stage*. It also exists with a native C interface as *LAPACKE_ssytrf_aa_2stage*.

4.16.84 ssytri_3x

SSYTRI_3X computes the inverse of a real symmetric indefinite matrix A using the factorization computed by SSYTRF_RK or SSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytri_3x(UPLO, N, A, LDA, E, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void ssytri_3x_(const char *uplo, const armpl_int_t *n, float *a,
                const armpl_int_t *lda, const float *e,
                const armpl_int_t *ipiv, float *work, const armpl_int_t *nb,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by SYTRF_RK and SSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the symmetric inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is REAL

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by SSYTRF_RK or SSYTRF_BK.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (N+NB+1,NB+3). .

NB Input parameter.

NB is INTEGER

Block size.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *csytri_3x*, *dsytri_3x* and *zsytri_3x*.

4.16.85 ssytrs_aa_2stage

SSYTRS_AA_2STAGE solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*T*U^T or A = L*T*L^T computed by SSYTRF_AA_2STAGE.

Syntax

Fortran specification:

```
use armpl_library

subroutine ssytrs_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                            LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ssytrs_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       const armpl_int_t *nrhs, const float *a,
                       const armpl_int_t *lda, float *tb,
                       const armpl_int_t *ltb, const armpl_int_t *ipiv,
                       const armpl_int_t *ipiv2, float *b,
                       const armpl_int_t *ldb, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). Details of factors computed by SSYTRF_AA_2STAGE.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is REAL

TB is an array, dimension (LTB). Details of factors computed by SSYTRF_AA_2STAGE.

LTB Input parameter.

The size of the array TB. LTB >= 4*N.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by SSYTRF_AA_2STAGE.

IPIV2 Input parameter.

IPIV2 is INTEGER array, dimension (N)

Details of the interchanges as computed by SSYTRF_AA_2STAGE.

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_aa_2stage*, *dsytrs_aa_2stage* and *zsytrs_aa_2stage*. It also exists with a native C interface as *LAPACKE_ssytrs_aa_2stage*.

4.16.86 strevc3

strevc3 computes some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T. Matrices of this type are produced by the Schur factorization of a real general matrix: A = Q*T*Q^T , as computed by SHSEQR.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
T*x = w*x,      (y**H)*T = w*(y**H)
```

where y^H denotes the conjugate transpose of y. The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of T.

This routine returns the matrices X and/or Y of right and left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input matrix. If Q is the orthogonal factor that reduces a matrix A to Schur form T, then Q*X and Q*Y are the matrices of right and left eigenvectors of A.

This uses a Level 3 BLAS version of the back transformation.

Syntax

Fortran specification:

```
use armpl_library

subroutine strevc3(SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, MM, M,
                   WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void strevc3_(const char *side, const char *howmny, armpl_int_t *select,
              const armpl_int_t *n, const float *t, const armpl_int_t *ldt,
              float *vl, const armpl_int_t *ldvl, float *vr,
              const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
              float *work, const armpl_int_t *lwork, armpl_int_t *info,
              ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

HOWMNY is CHARACTER*1

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed by the matrices in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, as indicated by the logical array SELECT.

SELECT Input and output parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If w(j) is a real eigenvalue, the corresponding real eigenvector is computed if SELECT(j) is .TRUE.. If w(j) and w(j+1) are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either SELECT(j) or SELECT(j+1) is .TRUE., and on exit SELECT(j) is set to .TRUE. and SELECT(j+1) is set to .FALSE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input parameter.

T is REAL

T is an array, dimension (LDT, N). The upper quasi-triangular matrix T in Schur canonical form.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input and output parameter.

VL is REAL

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1, and if SIDE = 'L' or 'B', LDVL >= N.

VR Input and output parameter.

VR is REAL

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of array WORK. LWORK >= max(1,3*N). For optimum performance, LWORK >= N + 2*N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrevc3*, *dtrevc3* and *ztrevc3*.

4.16.87 strtrs

strtrs solves a triangular system of the form

```
A * X = B  or  A**T * X = B,
```

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine strtrs(UPLO, TRANS, DIAG, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void strtrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs, const float *a,
             const armpl_int_t *lda, float *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose = Transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is REAL

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *ctrtrs*, *dtrtrs* and *ztrtrs*. It also exists with a native C interface as *LAPACKE_strtrs*.

4.16.88 zgetsls

zgetsls solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, using a tall sk

The following options are provided:

* If TRANS = 'N' and m >= n: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize || B - A*X ||.

* If TRANS = 'N' and m < n: find the minimum norm solution of an underdetermined system A * X = B.

* If TRANS = 'C' and m >= n: find the minimum norm solution of an undetermined system A^T * X = B.

* If TRANS = 'C' and m < n: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize || B - A^T * X ||.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Syntax

Fortran specification:

```
use armpl_library

subroutine zgetsls(TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zgetsls_(const char *trans, const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
              const armpl_int_t *lda, armpl_doublecomplex_t *b,
              const armpl_int_t *ldb, armpl_doublecomplex_t *work,
              const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': the linear system involves A; = 'C': the linear system involves A^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >=0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, A is overwritten by details of its QR or LQ factorization as returned by ZGEQR or ZGELQ.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'C'. On exit, if INFO = 0, B is overwritten by the solution vectors, stored columnwise: if TRANS = 'N' and m >= n, rows 1 to n of B contain the least

squares solution vectors. if TRANS = 'N' and m < n, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'C' and m >= n, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'C' and m < n, rows 1 to M of B contain the least squares solution vectors.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= MAX(1, M, N).

WORK Output parameter.

(workspace) COMPLEX*16

(workspace) is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) contains optimal (or either minimal or optimal, if query was assumed) LWORK. See LWORK for details.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If LWORK = -1 or -2, then a workspace query is assumed. If LWORK = -1, the routine calculates optimal size of WORK for the optimal performance and returns this value in WORK(1). If LWORK = -2, the routine calculates minimal size of WORK and returns this value in WORK(1).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

4.16.89 zhb2st_kernels

ZHB2ST_KERNELS is an internal routine used by the ZHETRD_HB2ST subroutine.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhb2st_kernels(UPLO, WANTZ, TTYPE, ST, ED, SWEEP, N, NB, IB, A,
                          LDA, V, TAU, LDVT, WORK)
```

C specification:

```
#include "armpl.h"

void zhb2st_kernels_(const char *uplo, const armpl_int_t *wantz,
                     const armpl_int_t *ttype, const armpl_int_t *st,
                     const armpl_int_t *ed, const armpl_int_t *sweep,
                     const armpl_int_t *n, const armpl_int_t *nb,
                     const armpl_int_t *ib, armpl_doublecomplex_t *a,
                     const armpl_int_t *lda, armpl_doublecomplex_t *v,
                     armpl_doublecomplex_t *tau, const armpl_int_t *ldvt,
                     const armpl_doublecomplex_t *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

WANTZ Input parameter.

WANTZ is LOGICAL which indicate if Eigenvalue are requested or both

Eigenvalue/Eigenvectors.

TTYPE Input parameter.

TTYPE is INTEGER

ST Input parameter.

ST is INTEGER

internal parameter for indices.

ED Input parameter.

ED is INTEGER

internal parameter for indices.

SWEEP Input parameter.

SWEEP is INTEGER

internal parameter for indices.

N Input parameter.

N is INTEGER. The order of the matrix A.

NB Input parameter.

NB is INTEGER. The size of the band.

IB Input parameter.

IB is INTEGER.

A Input and output parameter.

A is COMPLEX*16 array. A pointer to the matrix A.

LDA Input parameter.

LDA is INTEGER. The leading dimension of the matrix A.

V Output parameter.

V is COMPLEX*16

V is an array, dimension 2*n if eigenvalues only are. requested or to be queried for vectors.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (2*n).. The scalar factors of the Householder reflectors are stored in this array.

LDVT Input parameter.

LDVT is INTEGER.

WORK Input parameter.

WORK is COMPLEX*16 array. Workspace of size nb.

Related Information

For this routine in other precisions, please see *chb2st_kernels*.

4.16.90 zhbev_2stage

ZHBEV_2STAGE computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A using the 2stage technique for the reduction to tridiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbev_2stage(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK,
                        RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhbev_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                   const armpl_int_t *kd, armpl_doublecomplex_t *ab,
                   const armpl_int_t *ldab, double *w,
                   armpl_doublecomplex_t *z, const armpl_int_t *ldz,
                   armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                   double *rwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension LWORK. On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(1,3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *chbev_2stage*. It also exists with a native C interface as *LAPACKE_zhbev_2stage*.

4.16.91 zhbevd_2stage

ZHBEVD_2STAGE computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbevd_2stage(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK, LWORK,
                         RWORK, LRWORK, IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhbevd_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                    const armpl_int_t *kd, armpl_doublecomplex_t *ab,
                    const armpl_int_t *ldab, double *w,
                    armpl_doublecomplex_t *z, const armpl_int_t *ldz,
                    armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                    double *rwork, const armpl_int_t *lrwork,
                    armpl_int_t *iwork, const armpl_int_t *liwork,
                    armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, N). If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array,. dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5* N .

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

Related Information

For this routine in other precisions, please see *chbevd_2stage*. It also exists with a native C interface as *LAPACKE_zhbevd_2stage*.

4.16.92 zhbevx_2stage

ZHBEVX_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhbevx_2stage(JOBZ, RANGE, UPLO, N, KD, AB, LDAB, Q, LDQ, VL, VU,
                         IL, IU, ABSTOL, M, W, Z, LDZ, WORK, LWORK, RWORK,
                         IWORK, IFAIL, INFO)
```

C specification:

```
#include "armpl.h"

void zhbevx_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, const armpl_int_t *kd,
                    armpl_doublecomplex_t *ab, const armpl_int_t *ldab,
                    armpl_doublecomplex_t *q, const armpl_int_t *ldq,
                    const double *vl, const double *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const double *abstol,
                    armpl_int_t *m, double *w, armpl_doublecomplex_t *z,
                    const armpl_int_t *ldz, armpl_doublecomplex_t *work,
                    const armpl_int_t *lwork, double *rwork,
                    armpl_int_t *iwork, armpl_int_t *ifail, armpl_int_t *info,
                    ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found; = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD + 1.

Q Output parameter.

Q is COMPLEX*16

Q is an array, dimension (LDQ, N). If JOBZ = 'V', the N-by-N unitary matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AB to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = (2KD+1)* N + KD*NTHREADS where KD is the size of the band. NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *chbevx_2stage*. It also exists with a native C interface as *LAPACKE_zhbevx_2stage*.

4.16.93 zheev_2stage

ZHEEV_2STAGE computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A using the 2stage technique for the reduction to tridiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheev_2stage(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zheev_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                   armpl_doublecomplex_t *a, const armpl_int_t *lda,
                   double *w, armpl_doublecomplex_t *work,
                   const armpl_int_t *lwork, double *rwork, armpl_int_t *info,
                   ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

4.16.94 zheevd_2stage

ZHEEVD_2STAGE computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheevd_2stage(JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, RWORK, LRWORK,
                         IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zheevd_2stage_(const char *jobz, const char *uplo, const armpl_int_t *n,
                    armpl_doublecomplex_t *a, const armpl_int_t *lda,
                    double *w, armpl_doublecomplex_t *work,
                    const armpl_int_t *lwork, double *rwork,
                    const armpl_int_t *lrwork, armpl_int_t *iwork,
                    const armpl_int_t *liwork, armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N+1 = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N+1 where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be at least 2* N + N**2

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array,. dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of the array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5* N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i and JOBZ = 'N', then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if INFO = i and JOBZ = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

4.16.95 zheevr_2stage

ZHEEVR_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ZHEEVR_2STAGE first reduces the matrix A to tridiagonal form T with a call to ZHETRD. Then, whenever possible, ZHEEVR_2STAGE calls ZSTEMR to compute eigenspectrum using Relatively Robust Representations. ZSTEMR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows.

For each unreduced block (submatrix) of T,

```
(a) Compute T - sigma I  = L D L^T, so that L and D
    define all the wanted eigenvalues to high relative accuracy.
    This means that small relative changes in the entries of D and L
    cause only small relative changes in the eigenvalues and
    eigenvectors. The standard (unfactored) representation of the
    tridiagonal matrix T does not have this property in general.
(b) Compute the eigenvalues to suitable accuracy.
    If the eigenvectors are desired, the algorithm attains full
    accuracy of the computed eigenvalues only right before
    the corresponding vectors have to be computed, see steps c) and d).
(c) For each cluster of close eigenvalues, select a new
    shift close to the cluster, find a new factorization, and refine
    the shifted eigenvalues to suitable accuracy.
(d) For each eigenvalue with a large enough relative separation compute
    the corresponding eigenvector by forming a rank revealing twisted
    factorization. Go back to (c) for any clusters that remain.
```

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see DSTEMR's documentation and: - Inderjit S. Dhillon and Beresford N. Parlett: "Multiple representations

```
 to compute orthogonal eigenvectors of symmetric tridiagonal matrices,"
Linear Algebra and its Applications, 387(1), pp. 1-28, August 2004.
```

- Inderjit Dhillon and Beresford Parlett: "Orthogonal Eigenvectors and

```
 Relative Gaps," SIAM Journal on Matrix Analysis and Applications, Vol. 25,
2004.  Also LAPACK Working Note 154.
```

- Inderjit Dhillon: "A new O(n^2) algorithm for the symmetric

```
 tridiagonal eigenvalue/eigenvector problem",
Computer Science Division Technical Report No. UCB/CSD-97-971,
UC Berkeley, May 1997.
```

Note 1 : ZHEEVR_2STAGE calls ZSTEMR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. ZHEEVR_2STAGE calls DSTEBZ and ZSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of ZSTEMR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheevr_2stage(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL,
                         M, W, Z, LDZ, ISUPPZ, WORK, LWORK, RWORK, LRWORK,
                         IWORK, LIWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zheevr_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, armpl_doublecomplex_t *a,
                    const armpl_int_t *lda, const double *vl,
                    const double *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const double *abstol,
                    armpl_int_t *m, double *w, armpl_doublecomplex_t *z,
                    const armpl_int_t *ldz, armpl_int_t *isuppz,
                    armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                    double *rwork, const armpl_int_t *lrwork,
                    armpl_int_t *iwork, const armpl_int_t *liwork,
                    armpl_int_t *info, ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found. For RANGE = 'V' or 'I' and IU - IL < N - 1, DSTEBZ and ZSTEIN are called

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See “Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy,” by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to DLAMCH(‘Safe minimum’). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but furutre releases will. See J. Barlow and J. Demmel, “Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices”, LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = ‘A’, M = N, and if RANGE = ‘I’, M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). The first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = ‘V’, then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = ‘N’, then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = ‘V’, the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = ‘V’, LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i). This is an output of ZSTEMR (tridiagonal matrix). The support of the eigenvectors of A is typically 1:N because of the unitary transformations applied by ZUNMTR. Implemented only for RANGE = ‘A’ or ‘I’ and IU - IL = N - 1

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If JOBZ = ‘N’ and N > 1, LWORK must be queried. LWORK = MAX(1, 26*N, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = ‘V’ and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (MAX(1, LRWORK)). On exit, if INFO = 0, RWORK(1) returns the optimal (and minimal) LRWORK.

LRWORK Input parameter.

LRWORK is INTEGER

The length of the array RWORK. LRWORK >= max(1,24*N).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

IWORK Output parameter.

IWORK is INTEGER array, dimension (MAX(1, LIWORK))

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK Input parameter.

LIWORK is INTEGER

The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal sizes of the WORK, RWORK and IWORK arrays, returns these values as the first entries of the WORK, RWORK and IWORK arrays, and no error message related to LWORK or LRWORK or LIWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: Internal error

Related Information

For this routine in other precisions, please see *cheevr_2stage*. It also exists with a native C interface as *LAPACKE_zheevr_2stage*.

4.16.96 zheevx_2stage

ZHEEVX_2STAGE computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A using the 2stage technique for the reduction to tridiagonal. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Syntax

Fortran specification:

```
use armpl_library

subroutine zheevx_2stage(JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU, ABSTOL,
                         M, W, Z, LDZ, WORK, LWORK, RWORK, IWORK, IFAIL,
                         INFO)
```

C specification:

```
#include "armpl.h"

void zheevx_2stage_(const char *jobz, const char *range, const char *uplo,
                    const armpl_int_t *n, armpl_doublecomplex_t *a,
                    const armpl_int_t *lda, const double *vl,
                    const double *vu, const armpl_int_t *il,
                    const armpl_int_t *iu, const double *abstol,
                    armpl_int_t *m, double *w, armpl_doublecomplex_t *z,
                    const armpl_int_t *ldz, armpl_doublecomplex_t *work,
                    const armpl_int_t *lwork, double *rwork,
                    armpl_int_t *iwork, armpl_int_t *ifail, armpl_int_t *info,
                    ... );
```

Parameters

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

RANGE Input parameter.

RANGE is CHARACTER*1

= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

VL Input parameter.

VL is DOUBLE PRECISION

If RANGE='V', the lower bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU Input parameter.

VU is DOUBLE PRECISION

If RANGE='V', the upper bound of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL Input parameter.

IL is INTEGER

If RANGE='I', the index of the smallest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU Input parameter.

IU is INTEGER

If RANGE='I', the index of the largest eigenvalue to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL Input parameter.

ABSTOL is DOUBLE PRECISION

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

M Output parameter.

M is INTEGER

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z Output parameter.

Z is COMPLEX*16

Z is an array, dimension (LDZ, max(1, M)). If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1, M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, 8*N, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (7*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (5*N)

IFAIL Output parameter.

IFAIL is INTEGER array, dimension (N)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

Related Information

For this routine in other precisions, please see *cheevx_2stage*. It also exists with a native C interface as *LAPACKE_zheevx_2stage*.

4.16.97 zhegv_2stage

ZHEGV_2STAGE computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. This routine use the 2stage technique for the reduction to tridiagonal which showed higher performance on recent architecture and for large sizes N>2000.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhegv_2stage(ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK,
                        RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhegv_2stage_(const armpl_int_t *itype, const char *jobz,
                   const char *uplo, const armpl_int_t *n,
                   armpl_doublecomplex_t *a, const armpl_int_t *lda,
                   armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                   double *w, armpl_doublecomplex_t *work,
                   const armpl_int_t *lwork, double *rwork, armpl_int_t *info,
                   ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

Specifies the problem type to be solved: = 1: A*x = (lambda)*B*x = 2: A*B*x = (lambda)*x = 3: B*A*x = (lambda)*x

JOBZ Input parameter.

JOBZ is CHARACTER*1

= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. Not available in this release.

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangles of A and B are stored; = 'L': Lower triangles of A and B are stored.

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z^H *B*Z = I; if ITYPE = 3, Z^H *inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, N). On entry, the Hermitian positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^H *U or B = L*L^H .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

W Output parameter.

W is DOUBLE PRECISION

W is an array, dimension (N). If INFO = 0, the eigenvalues in ascending order.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)). On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK Input parameter.

LWORK is INTEGER

The length of the array WORK. LWORK >= 1, when N <= 1; otherwise If JOBZ = 'N' and N > 1, LWORK must be queried. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)* N + N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N + N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1. If JOBZ = 'V' and N > 1, LWORK must be queried. Not yet available

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (max(1, 3*N-2)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: ZPOTRF or ZHEEV returned an error code: <= N: if INFO = i, ZHEEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Related Information

For this routine in other precisions, please see *chegv_2stage*. It also exists with a native C interface as *LAPACKE_zhegv_2stage*.

4.16.98 zhesv_aa_2stage

ZHESV_AA_2STAGE computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

Aasen's 2-stage algorithm is used to factor A as

```
A = U * T * U**H,  if UPLO = 'U', or
A = L * T * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is Hermitian and band. The matrix T is then LU-factored with partial pivoting. The factored form of A is then used to solve the system of equations A * X = B.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhesv_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                           LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhesv_aa_2stage_(const char *uplo, const armpl_int_t *n,
                      const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
                      const armpl_int_t *lda, armpl_doublecomplex_t *tb,
                      const armpl_int_t *ltb, armpl_int_t *ipiv,
                      armpl_int_t *ipiv2, armpl_doublecomplex_t *b,
                      const armpl_int_t *ldb, armpl_doublecomplex_t *work,
                      const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX*16

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16 workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *chesv_aa_2stage*. It also exists with a native C interface as *LAPACKE_zhesv_aa_2stage*.

4.16.99 zhetf2_rk

ZHETF2_RK computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetf2_rk(UPLO, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zhetf2_rk_(const char *uplo, const armpl_int_t *n,
                armpl_doublecomplex_t *a, const armpl_int_t *lda,
                armpl_doublecomplex_t *e, armpl_int_t *ipiv,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX*16

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *chetf2_rk*.

4.16.100 zhetrd_2stage

ZHETRD_2STAGE reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q1^H$ $Q2^H$ * A * Q2 * Q1 = T.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrd_2stage(VECT, UPLO, N, A, LDA, D, E, TAU, HOUS2, LHOUS2,
                         WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrd_2stage_(const char *vect, const char *uplo, const armpl_int_t *n,
                    armpl_doublecomplex_t *a, const armpl_int_t *lda,
                    double *d, double *e, armpl_doublecomplex_t *tau,
                    armpl_doublecomplex_t *hous2, const armpl_int_t *lhous2,
                    armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                    armpl_int_t *info, ... );
```

Parameters

VECT Input parameter.

VECT is CHARACTER*1

= 'N': No need for the Housholder representation, in particular for the second stage (Band to tridiagonal) and thus LHOUS2 is of size max(1, 4*N); = 'V': the Householder representation is needed to either generate Q1 Q2 or to apply Q1 Q2, then LHOUS2 is to be queried and computed. (NOT AVAILABLE IN THIS RELEASE).

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the band superdiagonal of A are overwritten by the corresponding elements of the internal band-diagonal matrix AB, and the elements above the KD superdiagonal, with the array TAU, represent the unitary matrix

Q1 as a product of elementary reflectors; if UPLO = 'L', the diagonal and band subdiagonal of A are overwritten by the corresponding elements of the internal band-diagonal matrix AB, and the elements below the KD subdiagonal, with the array TAU, represent the unitary matrix Q1 as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is DOUBLE PRECISION

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T.

E Output parameter.

E is DOUBLE PRECISION

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-KD). The scalar factors of the elementary reflectors of the first stage (see Further Details).

HOUS2 Output parameter.

HOUS2 is COMPLEX*16

HOUS2 is an array, dimension LHOUS2, that. store the Householder representation of the stage2 band to tridiagonal.

LHOUS2 Input parameter.

LHOUS2 is INTEGER

The dimension of the array HOUS2. LHOUS2 = MAX(1, dimension) If LWORK = -1, or LHOUS2=-1, then a query is assumed; the routine only calculates the optimal size of the HOUS2 array, returns this value as the first entry of the HOUS2 array, and no error message related to LHOUS2 is issued by XERBLA. LHOUS2 = MAX(1, dimension) where dimension = 4* N if VECT='N' not available now if VECT='H'

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK = MAX(1, dimension) If LWORK = -1, or LHOUS2=-1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA. LWORK = MAX(1, dimension) where dimension = max(stage1,stage2) + (KD+1)*N = N*KD + N*max(KD+1,FACTOPTNB) + max(2*KD*KD, KD*NTHREADS) + (KD+1)* N where KD is the blocking size of the reduction, FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice NTHREADS is the number of threads used when openMP compilation is enabled, otherwise =1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chetrd_2stage*.

4.16.101 zhetrd_he2hb

ZHETRD_HE2HB reduces a complex Hermitian matrix A to complex Hermitian band-diagonal form AB by a unitary similarity transformation: Q^H * A * Q = AB.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrd_he2hb(UPLO, N, KD, A, LDA, AB, LDAB, TAU, WORK, LWORK,
                        INFO)
```

C specification:

```
#include "armpl.h"

void zhetrd_he2hb_(const char *uplo, const armpl_int_t *n,
                   const armpl_int_t *kd, armpl_doublecomplex_t *a,
                   const armpl_int_t *lda, armpl_doublecomplex_t *ab,
                   const armpl_int_t *ldab, armpl_doublecomplex_t *tau,
                   armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                   armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of superdiagonals of the reduced matrix if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0. The reduced matrix is stored in the array AB.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written

by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AB Output parameter.

AB is COMPLEX*16

AB is an array, dimension (LDAB, N). On exit, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

TAU Output parameter.

TAU is COMPLEX*16

TAU is an array, dimension (N-KD). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (LWORK). On exit, if INFO = 0, or if LWORK=-1, WORK(1) returns the size of LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK which should be calculated by a workspace query. LWORK = MAX(1, LWORK_QUERY) If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA. LWORK_QUERY = N* KD + N*max(KD,FACTOPTNB) + 2*KD*KD where FACTOPTNB is the blocking used by the QR or LQ algorithm, usually FACTOPTNB=128 is a good choice otherwise putting LWORK=-1 will provide the size of WORK.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chetrd_he2hb*.

4.16.102 zhetrf_aa_2stage

ZHETRF_AA_2STAGE computes the factorization of a double hermitian matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a hermitian band matrix with the bandwidth of NB (NB is internally selected and stored in TB(1), and T is LU factorized with partial pivoting).

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrf_aa_2stage(UPLO, N, A, LDA, TB, LTB, IPIV, IPIV2, WORK,
                            LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrf_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       armpl_doublecomplex_t *a, const armpl_int_t *lda,
                       armpl_doublecomplex_t *tb, const armpl_int_t *ltb,
                       armpl_int_t *ipiv, armpl_int_t *ipiv2,
                       armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                       armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is COMPLEX workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *chetrf_aa_2stage*. It also exists with a native C interface as *LAPACKE_zhetrf_aa_2stage*.

4.16.103 zhetri_3x

ZHETRI_3X computes the inverse of a complex Hermitian indefinite matrix A using the factorization computed by ZHETRF_RK or ZHETRF_BK:

```
A = P*U*D*(U**H)*(P**T) or A = P*L*D*(L**H)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetri_3x(UPLO, N, A, LDA, E, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void zhetri_3x_(const char *uplo, const armpl_int_t *n,
                armpl_doublecomplex_t *a, const armpl_int_t *lda,
                const armpl_doublecomplex_t *e, const armpl_int_t *ipiv,
                armpl_doublecomplex_t *work, const armpl_int_t *nb,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by ZHETRF_RK and ZHETRF_BK: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the Hermitian inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHETRF_RK or ZHETRF_BK.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N+NB+1,NB+3). .

NB Input parameter.

NB is INTEGER

Block size.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

Related Information

For this routine in other precisions, please see *chetri_3x*.

4.16.104 zhetrs_aa_2stage

ZHETRS_AA_2STAGE solves a system of linear equations A*X = B with a hermitian matrix A using the factorization A = U*T*U^T or A = L*T*L^T computed by ZHETRF_AA_2STAGE.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhetrs_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                            LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zhetrs_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       const armpl_int_t *nrhs,
                       const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                       armpl_doublecomplex_t *tb, const armpl_int_t *ltb,
                       const armpl_int_t *ipiv, const armpl_int_t *ipiv2,
                       armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                       armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16``array, dimension (``LDA, N)

Details of factors computed by ZHETRF_AA_2STAGE.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX*16``array, dimension (``LTB)

Details of factors computed by ZHETRF_AA_2STAGE.

LTB Input parameter.

The size of the array TB. LTB >= 4*N.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by ZHETRF_AA_2STAGE.

IPIV2 Input parameter.

IPIV2 is INTEGER array, dimension (N)

Details of the interchanges as computed by ZHETRF_AA_2STAGE.

B Input and output parameter.

B is COMPLEX*16``array, dimension (``LDB, NRHS)

On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chetrs_aa_2stage*. It also exists with a native C interface as *LAPACKE_zhetrs_aa_2stage*.

4.16.105 zhptrs

zhptrs solves a system of linear equations A*X = B with a complex Hermitian matrix A stored in packed format using the factorization A = U*D*U^H or A = L*D*L^H computed by ZHPTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine zhptrs(UPLO, N, NRHS, AP, IPIV, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zhptrs_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *ap, const armpl_int_t *ipiv,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^H ; = 'L': Lower triangular, form is A = L*D*L^H .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP Input parameter.

AP is COMPLEX*16

AP is an array, dimension (N*(N+1)/2). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHPTRF, stored as a packed triangular matrix.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZHPTRF.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *chptrs*. It also exists with a native C interface as *LAPACKE_zhptrs*.

4.16.106 zlahef_rk

ZLAHEF_RK computes a partial factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**H U22**H )
```

A = (L11 0) (D 0) ($L11^H$ $L21^H$) if UPLO = 'L',

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

ZLAHEF_RK is an auxiliary routine called by ZHETRF_RK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine zlahef_rk(UPLO, N, NB, KB, A, LDA, E, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void zlahef_rk_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
                armpl_int_t *kb, armpl_doublecomplex_t *a,
                const armpl_int_t *lda, armpl_doublecomplex_t *e,
                armpl_int_t *ipiv, armpl_doublecomplex_t *w,
                const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX*16

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,N-KB+1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,N-KB+1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,N-KB+1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *clahef_rk*.

4.16.107 zlasyf_rk

ZLASYF_RK computes a partial factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L',

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

ZLASYF_RK is an auxiliary routine called by ZSYTRF_RK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine zlasyf_rk(UPLO, N, NB, KB, A, LDA, E, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void zlasyf_rk_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
                armpl_int_t *kb, armpl_doublecomplex_t *a,
                const armpl_int_t *lda, armpl_doublecomplex_t *e,
                armpl_int_t *ipiv, armpl_doublecomplex_t *w,
                const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX*16

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,N-KB+1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,N-KB+1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,N-KB+1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the submatrix A(1:N,1:KB). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b) is always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

W Output parameter.

W is COMPLEX*16

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *clasyf_rk*, *dlasyf_rk* and *slasyf_rk*.

4.16.108 zsyconvf

If parameter WAY = 'C': ZSYCONVF converts the factorization output format used in ZSYTRF provided on entry in parameter A into the factorization output format used in ZSYTRF_RK (or ZSYTRF_BK) that is stored on exit in parameters A and E. It also coverts in place details of the intechanges stored in IPIV from the format used in ZSYTRF into the format used in ZSYTRF_RK (or ZSYTRF_BK).

If parameter WAY = 'R': ZSYCONVF performs the conversion in reverse direction, i.e. converts the factorization output format used in ZSYTRF_RK (or ZSYTRF_BK) provided on entry in parameters A and E into the factorization output format used in ZSYTRF that is stored on exit in parameter A. It also coverts in place details of the intechanges stored in IPIV from the format used in ZSYTRF_RK (or ZSYTRF_BK) into the format used in ZSYTRF.

ZSYCONVF can also convert in Hermitian matrix case, i.e. between formats used in ZHETRF and ZHETRF_RK (or ZHETRF_BK).

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyconvf(UPLO, WAY, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zsyconvf_(const char *uplo, const char *way, const armpl_int_t *n,
               armpl_doublecomplex_t *a, const armpl_int_t *lda,
               armpl_doublecomplex_t *e, armpl_int_t *ipiv, armpl_int_t *info,
               ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix A. = 'U': Upper triangular = 'L': Lower triangular

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). 1) If WAY ='C':

On entry, contains factorization details in format used in ZSYTRF: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

On exit, contains factorization details in format used in ZSYTRF_RK or ZSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

2) If WAY = 'R':

On entry, contains factorization details in format used in ZSYTRF_RK or ZSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, contains factorization details in format used in ZSYTRF: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input and output parameter.

E is COMPLEX*16

E is an array, dimension (N). 1) If WAY ='C':

On entry, just a workspace.

On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

2) If WAY = 'R':

On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

On exit, is not changed

IPIV Input and output parameter.

IPIV is INTEGER array, dimension (N)

1) If WAY ='C': On entry, details of the interchanges and the block structure of D in the format used in ZSYTRF. On exit, details of the interchanges and the block structure of D in the format used in ZSYTRF_RK (or ZSYTRF_BK).

1) If WAY ='R': On entry, details of the interchanges and the block structure of D in the format used in ZSYTRF_RK (or ZSYTRF_BK). On exit, details of the interchanges and the block structure of D in the format used in ZSYTRF.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyconvf*, *dsyconvf* and *ssyconvf*.

4.16.109 zsyconvf_rook

If parameter WAY = 'C': ZSYCONVF_ROOK converts the factorization output format used in ZSYTRF_ROOK provided on entry in parameter A into the factorization output format used in ZSYTRF_RK (or ZSYTRF_BK) that is stored on exit in parameters A and E. IPIV format for ZSYTRF_ROOK and ZSYTRF_RK (or ZSYTRF_BK) is the same and is not converted.

If parameter WAY = 'R': ZSYCONVF_ROOK performs the conversion in reverse direction, i.e. converts the factorization output format used in ZSYTRF_RK (or ZSYTRF_BK) provided on entry in parameters A and E into the factorization output format used in ZSYTRF_ROOK that is stored on exit in parameter A. IPIV format for ZSYTRF_ROOK and ZSYTRF_RK (or ZSYTRF_BK) is the same and is not converted.

ZSYCONVF_ROOK can also convert in Hermitian matrix case, i.e. between formats used in ZHETRF_ROOK and ZHETRF_RK (or ZHETRF_BK).

Syntax

Fortran specification:

```
use armpl_library

subroutine zsyconvf_rook(UPLO, WAY, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zsyconvf_rook_(const char *uplo, const char *way, const armpl_int_t *n,
                    armpl_doublecomplex_t *a, const armpl_int_t *lda,
                    armpl_doublecomplex_t *e, const armpl_int_t *ipiv,
                    armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix A. = 'U': Upper triangular = 'L': Lower triangular

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). 1) If WAY ='C':

On entry, contains factorization details in format used in ZSYTRF_ROOK: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

On exit, contains factorization details in format used in ZSYTRF_RK or ZSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

2) If WAY = 'R':

On entry, contains factorization details in format used in ZSYTRF_RK or ZSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, contains factorization details in format used in ZSYTRF_ROOK: a) all elements of the symmetric block diagonal matrix D on the diagonal of A and on superdiagonal (or subdiagonal) of A, and b) If UPLO = 'U': multipliers used to obtain factor U in the superdiagonal part of A. If UPLO = 'L': multipliers used to obtain factor L in the superdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input and output parameter.

E is COMPLEX*16

E is an array, dimension (N). 1) If WAY ='C':

On entry, just a workspace.

On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

2) If WAY = 'R':

On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i),i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i),i=1:N-1, E(N) not referenced.

On exit, is not changed

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

On entry, details of the interchanges and the block structure of D as determined: 1) by ZSYTRF_ROOK, if WAY ='C'; 2) by ZSYTRF_RK (or ZSYTRF_BK), if WAY ='R'. The IPIV format is the same for all these routines.

On exit, is not changed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csyconvf_rook*, *dsyconvf_rook* and *ssyconvf_rook*.

4.16.110 zsysv_aa_2stage

ZSYSV_AA_2STAGE computes the solution to a complex system of linear equations

```
A * X = B,
```

where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Aasen's 2-stage algorithm is used to factor A as

```
A = U * T * U**H,  if UPLO = 'U', or
A = L * T * L**H,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is symmetric and band. The matrix T is then LU-factored with partial pivoting. The factored form of A is then used to solve the system of equations A * X = B.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsysv_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                           LDB, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsysv_aa_2stage_(const char *uplo, const armpl_int_t *n,
                      const armpl_int_t *nrhs, armpl_doublecomplex_t *a,
                      const armpl_int_t *lda, armpl_doublecomplex_t *tb,
                      const armpl_int_t *ltb, armpl_int_t *ipiv,
                      armpl_int_t *ipiv2, armpl_doublecomplex_t *b,
                      const armpl_int_t *ldb, armpl_doublecomplex_t *work,
                      const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX*16

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

WORK Output parameter.

WORK is COMPLEX*16 workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *csysv_aa_2stage*, *dsysv_aa_2stage* and *ssysv_aa_2stage*. It also exists with a native C interface as *LAPACKE_zsysv_aa_2stage*.

4.16.111 zsytf2_rk

ZSYTF2_RK computes the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS. For more information see Further Details section.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytf2_rk(UPLO, N, A, LDA, E, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void zsytf2_rk_(const char *uplo, const armpl_int_t *n,
                armpl_doublecomplex_t *a, const armpl_int_t *lda,
                armpl_doublecomplex_t *e, armpl_int_t *ipiv,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U': the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced.

If UPLO = 'L': the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, contains: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is COMPLEX*16

E is an array, dimension (N). On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) is set to 0; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) is set to 0.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is set to 0 in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

IPIV describes the permutation matrix P in the factorization of matrix A as follows. The absolute value of IPIV(k) represents the index of row and column that were interchanged with the k-th row and column. The value of UPLO describes the order in which the interchanges were applied. Also, the sign of IPIV represents the block structure of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks which correspond to 1 or 2 interchanges at each factorization step. For more info see Further Details section.

If UPLO = 'U', (in factorization order, k decreases from N to 1): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N); If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k-1) < 0 means: D(k-1:k,k-1:k) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k-1) != k-1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k-1) = k-1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) <= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

If UPLO = 'L', (in factorization order, k increases from 1 to N): a) A single positive entry IPIV(k) > 0 means: D(k,k) is a 1-by-1 diagonal block. If IPIV(k) != k, rows and columns k and IPIV(k) were interchanged in the matrix A(1:N,1:N). If IPIV(k) = k, no interchange occurred.

b) A pair of consecutive negative entries IPIV(k) < 0 and IPIV(k+1) < 0 means: D(k:k+1,k:k+1) is a 2-by-2 diagonal block. (NOTE: negative entries in IPIV appear ONLY in pairs). 1) If -IPIV(k) != k, rows and columns k and -IPIV(k) were interchanged in the matrix A(1:N,1:N). If -IPIV(k) = k, no interchange occurred. 2) If -IPIV(k+1) != k+1, rows and columns k-1 and -IPIV(k-1) were interchanged in the matrix A(1:N,1:N). If -IPIV(k+1) = k+1, no interchange occurred.

c) In both cases a) and b), always ABS(IPIV(k)) >= k.

d) NOTE: Any entry IPIV(k) is always NONZERO on output.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

< 0: If INFO = -k, the k-th argument had an illegal value

> 0: If INFO = k, the matrix A is singular, because: If UPLO = 'U': column k in the upper triangular part of A contains all zeros. If UPLO = 'L': column k in the lower triangular part of A contains all zeros.

Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NOTE: INFO only stores the first occurrence of a singularity, any subsequent occurrence of singularity is not stored in INFO even though the factorization always completes.

Related Information

For this routine in other precisions, please see *csytf2_rk*, *dsytf2_rk* and *ssytf2_rk*.

4.16.112 zsytrf_aa_2stage

ZSYTRF_AA_2STAGE computes the factorization of a complex symmetric matrix A using the Aasen's algorithm. The form of the factorization is

```
A = U*T*U**T  or  A = L*T*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is a complex symmetric band matrix with the bandwidth of NB (NB is internally selected and stored in TB(1), and T is LU factorized with partial pivoting).

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrf_aa_2stage(UPLO, N, A, LDA, TB, LTB, IPIV, IPIV2, WORK,
                            LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrf_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       armpl_doublecomplex_t *a, const armpl_int_t *lda,
                       armpl_doublecomplex_t *tb, const armpl_int_t *ltb,
                       armpl_int_t *ipiv, armpl_int_t *ipiv2,
                       armpl_doublecomplex_t *work, const armpl_int_t *lwork,
                       armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, the hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, L is stored below (or above) the subdiaonal blocks, when UPLO is 'L' (or 'U').

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX*16

TB is an array, dimension (LTB). On exit, details of the LU factorization of the band matrix.

LTB Input parameter.

The size of the array TB. LTB >= 4*N, internally

used to select NB such that LTB >= (3*NB+1)*N.

If LTB = -1, then a workspace query is assumed; the routine only calculates the optimal size of LTB, returns this value as the first entry of TB, and no error message related to LTB is issued by XERBLA.

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of A were interchanged with the row and column IPIV(k).

IPIV2 Output parameter.

IPIV is INTEGER array, dimension (N)

On exit, it contains the details of the interchanges, i.e., the row and column k of T were interchanged with the row and column IPIV(k).

WORK Output parameter.

WORK is COMPLEX*16 workspace of size LWORK

LWORK Input parameter.

The size of WORK. LWORK >= N, internally used to select NB

such that LWORK >= N*NB.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = i, band LU factorization failed on i-th column

Related Information

For this routine in other precisions, please see *csytrf_aa_2stage*, *dsytrf_aa_2stage* and *ssytrf_aa_2stage*. It also exists with a native C interface as *LAPACKE_zsytrf_aa_2stage*.

4.16.113 zsytri_3x

ZSYTRI_3X computes the inverse of a complex symmetric indefinite matrix A using the factorization computed by ZSYTRF_RK or ZSYTRF_BK:

```
A = P*U*D*(U**T)*(P**T) or A = P*L*D*(L**T)*(P**T),
```

where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytri_3x(UPLO, N, A, LDA, E, IPIV, WORK, NB, INFO)
```

C specification:

```
#include "armpl.h"

void zsytri_3x_(const char *uplo, const armpl_int_t *n,
                armpl_doublecomplex_t *a, const armpl_int_t *lda,
                const armpl_doublecomplex_t *e, const armpl_int_t *ipiv,
                armpl_doublecomplex_t *work, const armpl_int_t *nb,
                armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On entry, diagonal of the block diagonal matrix D and factors U or L as computed by ZSYTRF_RK and ZSYTRF_BK: a) ONLY diagonal elements of the symmetric block diagonal matrix D on the diagonal of A, i.e. D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D should be provided on entry in array E), and b) If UPLO = 'U': factor U in the superdiagonal part of A. If UPLO = 'L': factor L in the subdiagonal part of A.

On exit, if INFO = 0, the symmetric inverse of the original matrix. If UPLO = 'U': the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; If UPLO = 'L': the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Input parameter.

E is COMPLEX*16

E is an array, dimension (N). On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks, where If UPLO = 'U': E(i) = D(i-1,i), i=2:N, E(1) not referenced; If UPLO = 'L': E(i) = D(i+1,i), i=1:N-1, E(N) not referenced.

NOTE: For 1-by-1 diagonal block D(k), where 1 <= k <= N, the element E(k) is not referenced in both UPLO = 'U' or UPLO = 'L' cases.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by ZSYTRF_RK or ZSYTRF_BK.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (N+NB+1,NB+3). .

NB Input parameter.

NB is INTEGER

Block size.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

4.16.114 zsytrs_aa_2stage

ZSYTRS_AA_2STAGE solves a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*T*U^T or A = L*T*L^T computed by ZSYTRF_AA_2STAGE.

Syntax

Fortran specification:

```
use armpl_library

subroutine zsytrs_aa_2stage(UPLO, N, NRHS, A, LDA, TB, LTB, IPIV, IPIV2, B,
                            LDB, INFO)
```

C specification:

```
#include "armpl.h"

void zsytrs_aa_2stage_(const char *uplo, const armpl_int_t *n,
                       const armpl_int_t *nrhs,
                       const armpl_doublecomplex_t *a, const armpl_int_t *lda,
                       armpl_doublecomplex_t *tb, const armpl_int_t *ltb,
                       const armpl_int_t *ipiv, const armpl_int_t *ipiv2,
                       armpl_doublecomplex_t *b, const armpl_int_t *ldb,
                       armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*T*U^T ; = 'L': Lower triangular, form is A = L*T*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). Details of factors computed by ZSYTRF_AA_2STAGE.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TB Output parameter.

TB is COMPLEX*16

TB is an array, dimension (LTB). Details of factors computed by ZSYTRF_AA_2STAGE.

LTB Input parameter.

The size of the array TB. LTB >= 4*N.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges as computed by ZSYTRF_AA_2STAGE.

IPIV2 Input parameter.

IPIV2 is INTEGER array, dimension (N)

Details of the interchanges as computed by ZSYTRF_AA_2STAGE.

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *csytrs_aa_2stage*, *dsytrs_aa_2stage* and *ssytrs_aa_2stage*. It also exists with a native C interface as *LAPACKE_zsytrs_aa_2stage*.

4.16.115 ztrevc3

`ztrevc3` computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T. Matrices of this type are produced by the Schur factorization of a complex general matrix: A = Q*T*Q^H , as computed by ZHSEQR.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
T*x = w*x,      (y**H)*T = w*(y**H)
```

where y^H denotes the conjugate transpose of the vector y. The eigenvalues are not input to this routine, but are read directly from the diagonal of T.

This routine returns the matrices X and/or Y of right and left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input matrix. If Q is the unitary factor that reduces a matrix A to Schur form T, then Q*X and Q*Y are the matrices of right and left eigenvectors of A.

This uses a Level 3 BLAS version of the back transformation.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrevc3(SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR, LDVR, MM, M,
                   WORK, LWORK, RWORK, LRWORK, INFO)
```

C specification:

```
#include "armpl.h"

void ztrevc3_(const char *side, const char *howmny, const armpl_int_t *select,
              const armpl_int_t *n, armpl_doublecomplex_t *t,
              const armpl_int_t *ldt, armpl_doublecomplex_t *vl,
              const armpl_int_t *ldvl, armpl_doublecomplex_t *vr,
              const armpl_int_t *ldvr, const armpl_int_t *mm, armpl_int_t *m,
              armpl_doublecomplex_t *work, const armpl_int_t *lwork,
              double *rwork, const armpl_int_t *lrwork, armpl_int_t *info,
              ... );
```

Parameters

SIDE Input parameter.

`SIDE` is `CHARACTER*1`

= 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.

HOWMNY Input parameter.

`HOWMNY` is `CHARACTER*1`

= 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, backtransformed using the matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, as indicated by the logical array SELECT.

SELECT Input parameter.

SELECT is LOGICAL

SELECT is an array, dimension (N). If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. The eigenvector corresponding to the j-th eigenvalue is computed if SELECT(j) = .TRUE.. Not referenced if HOWMNY = 'A' or 'B'.

N Input parameter.

N is INTEGER

The order of the matrix T. N >= 0.

T Input and output parameter.

T is COMPLEX*16

T is an array, dimension (LDT, N). The upper triangular matrix T. T is modified, but restored on exit.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

VL Input and output parameter.

VL is COMPLEX*16

VL is an array, dimension (LDVL, MM). On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by ZHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. Not referenced if SIDE = 'R'.

LDVL Input parameter.

LDVL is INTEGER

The leading dimension of the array VL. LDVL >= 1, and if SIDE = 'L' or 'B', LDVL >= N.

VR Input and output parameter.

VR is COMPLEX*16

VR is an array, dimension (LDVR, MM). On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by ZHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. Not referenced if SIDE = 'L'.

LDVR Input parameter.

LDVR is INTEGER

The leading dimension of the array VR. LDVR >= 1, and if SIDE = 'R' or 'B', LDVR >= N.

MM Input parameter.

MM is INTEGER

The number of columns in the arrays VL and/or VR. MM >= M.

M Output parameter.

M is INTEGER

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK Output parameter.

WORK is COMPLEX*16

WORK is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of array WORK. LWORK >= max(1,2*N). For optimum performance, LWORK >= N + 2*N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK Output parameter.

RWORK is DOUBLE PRECISION

RWORK is an array, dimension (LRWORK) .

LRWORK Input parameter.

LRWORK is INTEGER

The dimension of array RWORK. LRWORK >= max(1, N).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *ctrevc3*, *dtrevc3* and *strevc3*.

4.16.116 ztrtrs

ztrtrs solves a triangular system of the form

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

Syntax

Fortran specification:

```
use armpl_library

subroutine ztrtrs(UPLO, TRANS, DIAG, N, NRHS, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void ztrtrs_(const char *uplo, const char *trans, const char *diag,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             const armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_doublecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': A is upper triangular; = 'L': A is lower triangular.

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

= 'N': A is non-unit triangular; = 'U': A is unit triangular.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A Input parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX*16

B is an array, dimension (LDB, NRHS). On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

Related Information

For this routine in other precisions, please see *ctrtrs*, *dtrtrs* and *strtrs*. It also exists with a native C interface as *LAPACKE_ztrtrs*.

4.17 LAPACK auxiliary routines

4.17.1 cgbtf2

cgbtf2 computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgbtf2(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void cgbtf2_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIV Output parameter.

IPIV is INTEGER array, dimension (min(M, N))

The pivot indices; for 1 <= i <= min(M, N), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value > 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dgbtf2*, *sgbtf2* and *zgbtf2*.

4.17.2 cgebd2

cgebd2 reduces a complex general m by n matrix A to upper or lower real bidiagonal form B by a unitary transformation: $Q^H * A * P = B$.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgebd2(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgebd2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda, float *d,
             float *e, armpl_singlecomplex_t *tauq,
```

(continues on next page)

(continued from previous page)

```
            armpl_singlecomplex_t *taup, armpl_singlecomplex_t *work,
            armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns in the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the m by n general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is REAL

D is an array, dimension (min(M, N)). The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (min(M, N)-1). The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ Output parameter.

TAUQ is COMPLEX

TAUQ is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP Output parameter.

TAUP is COMPLEX

TAUP is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (max(M, N)) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgebd2*, *sgebd2* and *zgebd2*.

4.17.3 cgehd2

cgehd2 reduces a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation: $Q^H * A * Q = H$.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgehd2(N, ILO, IHI, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgehd2_(const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *work, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL; otherwise they should be set to 1 and N respectively. See Further Details. 1 <= ILO <= IHI <= max(1, N).

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the n by n general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dgehd2*, *sgehd2* and *zgehd2*.

4.17.4 cgelq2

cgelq2 computes an LQ factorization of a complex m by n matrix A: A = L * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgelq2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgelq2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and below the diagonal of the array contain the m by min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgelq2*, *sgelq2* and *zgelq2*. It also exists with a native C interface as *LAPACKE_cgelq2*.

4.17.5 cgelqt3

cgelqt3 recursively computes a LQ factorization of a complex M-by-N matrix A, using the compact WY representation of
Based on the algorithm of Elmroth and Gustavson, IBM J. Res. Develop. Vol 44 No. 4 July 2000.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine cgelqt3(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void cgelqt3_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M =< N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the real M-by-N matrix A. On exit, the elements on and below the diagonal contain the N-by-N lower triangular matrix L; the elements above the diagonal are the rows of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgelqt3*, *sgelqt3* and *zgelqt3*.

4.17.6 cgeql2

cgeql2 computes a QL factorization of a complex m by n matrix A: A = Q * L.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeql2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeql2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the n by n lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the m by n lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeql2*, *sgeql2* and *zgeql2*.

4.17.7 cgeqr2

cgeqr2 computes a QR factorization of a complex m by n matrix A: A = Q * R.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeqr2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqr2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and above the diagonal of the array contain the min(m,n) by n upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeqr2*, *sgeqr2* and *zgeqr2*. It also exists with a native C interface as *LAPACKE_cgeqr2*.

4.17.8 cgeqr2p

cgeqr2p computes a QR factorization of a complex m by n matrix A: A = Q * R. The diagonal entries of R are real and nonnegative.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeqr2p(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqr2p_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, the elements on and above the diagonal of the array contain the min(m,n) by n upper trapezoidal matrix R (R is upper triangular if m >= n). The diagonal entries of R are real and nonnegative; the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeqr2p*, *sgeqr2p* and *zgeqr2p*.

4.17.9 cgeqrt2

cgeqrt2 computes a QR factorization of a complex M-by-N matrix A, using the compact WY representation of Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgeqrt2(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqrt2_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the complex M-by-N matrix A. On exit, the elements on and above the diagonal contain the N-by-N upper triangular matrix R; the elements below the diagonal are the columns of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeqrt2*, *sgeqrt2* and *zgeqrt2*. It also exists with a native C interface as *LAPACKE_cgeqrt2*.

4.17.10 cgeqrt3

cgeqrt3 recursively computes a QR factorization of a complex M-by-N matrix A, using the compact WY representation of Q.

Based on the algorithm of Elmroth and Gustavson, IBM J. Res. Develop. Vol 44 No. 4 July 2000.

Syntax

Fortran specification:

```
use armpl_library

recursive subroutine cgeqrt3(M, N, A, LDA, T, LDT, INFO)
```

C specification:

```
#include "armpl.h"

void cgeqrt3_(const armpl_int_t *m, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *t, const armpl_int_t *ldt,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= N.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the complex M-by-N matrix A. On exit, the elements on and above the diagonal contain the N-by-N upper triangular matrix R; the elements below the diagonal are the columns of V. See below for further details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, N). The N-by-N upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T; the elements below the diagonal are not used. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgeqrt3*, *sgeqrt3* and *zgeqrt3*. It also exists with a native C interface as *LAPACKE_cgeqrt3*.

4.17.11 cgerq2

cgerq2 computes an RQ factorization of a complex m by n matrix A: A = R * Q.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgerq2(M, N, A, LDA, TAU, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgerq2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the m by m upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the m by n upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors (see Further Details).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (M) .

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgerq2*, *sgerq2* and *zgerq2*.

4.17.12 cgesc2

cgesc2 solves a system of linear equations

```
A * X = scale* RHS
```

with a general N-by-N matrix A using the LU factorization with complete pivoting computed by CGETC2.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgesc2(N, A, LDA, RHS, IPIV, JPIV, SCALE)
```

C specification:

```
#include "armpl.h"

void cgesc2_(const armpl_int_t *n, const armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *rhs,
             const armpl_int_t *ipiv, const armpl_int_t *jpiv, float *scale);
```

Parameters

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the LU part of the factorization of the n-by-n matrix A computed by CGETC2: A = P * L * U * Q

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

RHS Input and output parameter.

RHS is COMPLEX

RHS is an array, dimension N.. On entry, the right hand side vector b. On exit, the solution vector X.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Input parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

SCALE Output parameter.

SCALE is REAL

On exit, SCALE contains the scale factor. SCALE is chosen 0 <= SCALE <= 1 to prevent owerflow in the solution.

Related Information

For this routine in other precisions, please see *dgesc2*, *sgesc2* and *zgesc2*.

4.17.13 cgetc2

cgetc2 computes an LU factorization, using complete pivoting, of the n-by-n matrix A. The factorization has the form A = P * L * U * Q, where P and Q are permutation matrices, L is lower triangular with unit diagonal elements and U is upper triangular.

This is a level 1 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgetc2(N, A, LDA, IPIV, JPIV, INFO)
```

C specification:

```
#include "armpl.h"

void cgetc2_(const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *jpiv,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the n-by-n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U*Q; the unit diagonal elements of L are not stored. If U(k, k) appears to be less than SMIN, U(k, k) is given the value of SMIN, giving a nonsingular perturbed system.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Output parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, U(k, k) is likely to produce overflow if one tries to solve for x in Ax = b. So U is perturbed to avoid the overflow.

Related Information

For this routine in other precisions, please see *dgetc2*, *sgetc2* and *zgetc2*.

4.17.14 cgetf2

`cgetf2` computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

```
A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 2 BLAS version of the algorithm.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgetf2(M, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void cgetf2_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *ipiv, armpl_int_t *info);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of the matrix `A`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of the matrix `A`. `N` >= 0.

A Input and output parameter.

`A` is `COMPLEX`

`A` is an array, dimension (`LDA`, `N`). On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization `A` = P*L*U; the unit diagonal elements of L are not stored.

LDA Input parameter.

`LDA` is `INTEGER`

The leading dimension of the array `A`. `LDA` >= max(1, `M`).

IPIV Output parameter.

`IPIV` is `INTEGER` array, dimension (min(`M`, `N`))

The pivot indices; for 1 <= i <= min(`M`, `N`), row i of the matrix was interchanged with row IPIV(i).

INFO Output parameter.

`INFO` is `INTEGER`

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dgetf2*, *sgetf2* and *zgetf2*. It also exists with a native C interface as *LAPACKE_cgetf2*.

4.17.15 cgsvj0

cgsvj0 is called from CGESVJ as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as CGESVJ does, but it does not check convergence (stopping criterion). Few tuning parameters (marked by [TP]) are available for the implementer.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgsvj0(JOBV, M, N, A, LDA, D, SVA, MV, V, LDV, EPS, SFMIN, TOL,
                  NSWEEP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgsvj0_(const char *jobv, const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *d, float *sva, const armpl_int_t *mv,
             armpl_singlecomplex_t *v, const armpl_int_t *ldv,
             const float *eps, const float *sfmin, const float *tol,
             const armpl_int_t *nsweep, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info, ... );
```

Parameters

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether the output from this procedure is used to compute the matrix V: = 'V': the product of the Jacobi rotations is accumulated by postmulyiplying the N-by-N array V. (See the description of V.) = 'A': the product of the Jacobi rotations is accumulated by postmulyiplying the MV-by-N array V. (See the descriptions of MV and V.) = 'N': the Jacobi rotations are not accumulated.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, M-by-N matrix A, such that A*diag(D) represents the input matrix. On exit, A_onexit * diag(D_onexit) represents the input matrix A*diag(D) post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of D, TOL and NSWEEP.)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Input and output parameter.

D is COMPLEX

D is an array, dimension (N). The array D accumulates the scaling factors from the complex scaled Jacobi rotations. On entry, A*diag(D) represents the input matrix. On exit, A_onexit*diag(D_onexit) represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of A, TOL and NSWEEP.)

SVA Input and output parameter.

SVA is REAL

SVA is an array, dimension (N). On entry, SVA contains the Euclidean norms of the columns of the matrix A*diag(D). On exit, SVA contains the Euclidean norms of the columns of the matrix A_onexit*diag(D_onexit).

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then MV is not referenced.

V Input and output parameter.

V is COMPLEX

V is an array, dimension (LDV, N). If JOBV .EQ. 'V' then N rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV .EQ. 'A' then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V', LDV .GE. N. If JOBV = 'A', LDV .GE. MV.

EPS Input parameter.

EPS is REAL

EPS = SLAMCH('Epsilon')

SFMIN Input parameter.

SFMIN is REAL

SFMIN = SLAMCH('Safe Minimum')

TOL Input parameter.

TOL is REAL

TOL is the threshold for Jacobi rotations. For a pair A(:,p), A(:,q) of pivot columns, the Jacobi rotation is applied only if ABS(COS(angle(A(:,p),A(:,q)))) .GT. TOL.

NSWEEP Input parameter.

NSWEEP is INTEGER

NSWEEP is the number of sweeps of Jacobi rotations to be performed.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

LWORK is the dimension of WORK. LWORK .GE. M.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgsvj0*, *sgsvj0* and *zgsvj0*.

4.17.16 cgsvj1

cgsvj1 is called from CGESVJ as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as CGESVJ does, but it targets only particular pivots and it does not check convergence (stopping criterion). Few tunning parameters (marked by [TP]) are available for the implementer.

Further Details

cgsvj1 applies few sweeps of Jacobi rotations in the column space of the input M-by-N matrix A. The pivot pairs are taken from the (1,2) off-diagonal block in the corresponding N-by-N Gram matrix A^T * A. The block-entries (tiles) of the (1,2) off-diagonal block are marked by the [x]'s in the following scheme:

```
| *  *  * [x] [x] [x]|
| *  *  * [x] [x] [x]|    Row-cycling in the nblr-by-nblc [x] blocks.
| *  *  * [x] [x] [x]|    Row-cyclic pivoting inside each [x] block.
|[x] [x] [x] *  *  * |
|[x] [x] [x] *  *  * |
|[x] [x] [x] *  *  * |
```

In terms of the columns of A, the first N1 columns are rotated 'against' the remaining N-N1 columns, trying to increase the angle between the corresponding subspaces. The off-diagonal block is N1-by(N-N1) and it is tiled using quadratic tiles of side KBL. Here, KBL is a tunning parmeter. The number of sweeps is given in NSWEEP and the orthogonality threshold is given in TOL.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgsvj1(JOBV, M, N, N1, A, LDA, D, SVA, MV, V, LDV, EPS, SFMIN, TOL,
                  NSWEEP, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void cgsvj1_(const char *jobv, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *n1, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *d, float *sva,
             const armpl_int_t *mv, armpl_singlecomplex_t *v,
             const armpl_int_t *ldv, const float *eps, const float *sfmin,
             const float *tol, const armpl_int_t *nsweep,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info, ... );
```

Parameters

JOBV Input parameter.

JOBV is CHARACTER*1

Specifies whether the output from this procedure is used to compute the matrix V: = 'V': the product of the Jacobi rotations is accumulated by postmulyiplying the N-by-N array V. (See the description of V.) = 'A': the product of the Jacobi rotations is accumulated by postmulyiplying the MV-by-N array V. (See the descriptions of MV and V.) = 'N': the Jacobi rotations are not accumulated.

M Input parameter.

M is INTEGER

The number of rows of the input matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the input matrix A. M >= N >= 0.

N1 Input parameter.

N1 is INTEGER

N1 specifies the 2 x 2 block partition, the first N1 columns are rotated 'against' the remaining N-N1 columns of A.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, M-by-N matrix A, such that A*diag(D) represents the input matrix. On exit, A_onexit * D_onexit represents the input matrix A*diag(D) post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of N1, D, TOL and NSWEEP.)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Input and output parameter.

D is COMPLEX

D is an array, dimension (N). The array D accumulates the scaling factors from the fast scaled Jacobi rotations. On entry, A*diag(D) represents the input matrix. On exit, A_onexit*diag(D_onexit) represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in TOL and NSWEEP, respectively. (See the descriptions of N1, A, TOL and NSWEEP.)

SVA Input and output parameter.

SVA is REAL

SVA is an array, dimension (N). On entry, SVA contains the Euclidean norms of the columns of the matrix A*diag(D). On exit, SVA contains the Euclidean norms of the columns of the matrix onexit*diag(D_onexit).

MV Input parameter.

MV is INTEGER

If JOBV .EQ. 'A', then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then MV is not referenced.

V Input and output parameter.

V is COMPLEX

V is an array, dimension (LDV, N). If JOBV .EQ. 'V' then N rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV .EQ. 'A' then MV rows of V are post-multipled by a sequence of Jacobi rotations. If JOBV = 'N', then V is not referenced.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V, LDV >= 1. If JOBV = 'V', LDV .GE. N. If JOBV = 'A', LDV .GE. MV.

EPS Input parameter.

EPS is REAL

EPS = SLAMCH('Epsilon')

SFMIN Input parameter.

SFMIN is REAL

SFMIN = SLAMCH('Safe Minimum')

TOL Input parameter.

TOL is REAL

TOL is the threshold for Jacobi rotations. For a pair A(:,p), A(:,q) of pivot columns, the Jacobi rotation is applied only if ABS(COS(angle(A(:,p),A(:,q)))) .GT. TOL.

NSWEEP Input parameter.

NSWEEP is INTEGER

NSWEEP is the number of sweeps of Jacobi rotations to be performed.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK) .

LWORK Input parameter.

LWORK is INTEGER

LWORK is the dimension of WORK. LWORK .GE. M.

INFO Output parameter.

INFO is INTEGER

= 0 : successful exit. < 0 : if INFO = -i, then the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dgsvj1*, *sgsvj1* and *zgsvj1*.

4.17.17 cgtts2

cgtts2 solves one of the systems of equations

```
A * X = B,  A**T * X = B,  or  A**H * X = B,
```

with a tridiagonal matrix A using the LU factorization computed by CGTTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine cgtts2(ITRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB)
```

C specification:

```
#include "armpl.h"

void cgtts2_(const armpl_int_t *itrans, const armpl_int_t *n,
             const armpl_int_t *nrhs, const armpl_singlecomplex_t *dl,
             const armpl_singlecomplex_t *d, const armpl_singlecomplex_t *du,
             const armpl_singlecomplex_t *du2, const armpl_int_t *ipiv,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb);
```

Parameters

ITRANS Input parameter.

ITRANS is INTEGER

Specifies the form of the system of equations. = 0: A * X = B (No transpose) = 1: A^T * X = B (Transpose) = 2: A^H * X = B (Conjugate transpose)

N Input parameter.

N is INTEGER

The order of the matrix A.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DL Input parameter.

DL is COMPLEX

DL is an array, dimension (N-1). The (n-1) multipliers that define the matrix L from the LU factorization of A.

D Input parameter.

D is COMPLEX

D is an array, dimension (N). The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

DU Input parameter.

DU is COMPLEX

DU is an array, dimension (N-1). The (n-1) elements of the first super-diagonal of U.

DU2 Input parameter.

DU2 is COMPLEX

DU2 is an array, dimension (N-2). The (n-2) elements of the second super-diagonal of U.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIV(i). IPIV(i) will always be either i or i+1; IPIV(i) = i indicates a row interchange was not required.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Related Information

For this routine in other precisions, please see *dgtts2*, *sgtts2* and *zgtts2*.

4.17.18 chegs2

chegs2 reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x, and A is overwritten by inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or B*A*x = lambda*x, and A is overwritten by U*A*U^H or L^H *A*L.

B must have been previously factorized as U^H *U or L*L^H by ZPOTRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine chegs2(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

C specification:

```
#include "armpl.h"

void chegs2_(const armpl_int_t *itype, const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_int_t *info, ... );
```

Parameters

ITYPE Input parameter.

ITYPE is INTEGER

= 1: compute inv(U^H)*A*inv(U) or inv(L)*A*inv(L^H); = 2 or 3: compute U*A*U^H or L^H *A*L.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored, and how B has been factorized. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrices A and B. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zhegs2*.

4.17.19 cheswapr

CHESWAPR applies an elementary permutation on the rows and the columns of a hermitian matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine cheswapr(UPLO, N, A, LDA, I1, I2)
```

C specification:

```
#include "armpl.h"

void cheswapr_(const char *uplo, const armpl_int_t *n,
               armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_int_t *i1, const armpl_int_t *i2, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

I1 Input parameter.

I1 is INTEGER

Index of the first row to swap

I2 Input parameter.

I2 is INTEGER

Index of the second row to swap

Related Information

For this routine in other precisions, please see *zheswapr*. It also exists with a native C interface as *LAPACKE_cheswapr*.

4.17.20 chetd2

chetd2 reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^H * A * Q = T$.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetd2(UPLO, N, A, LDA, D, E, TAU, INFO)
```

C specification:

```
#include "armpl.h"

void chetd2_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, float *d, float *e,
             armpl_singlecomplex_t *tau, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

D Output parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (N-1). The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors (see Further Details).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *zhetd2*.

4.17.21 chetf2

chetf2 computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^H is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetf2(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void chetf2_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *zhetf2*.

4.17.22 chetf2_rook

CHETF2_ROOK computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^H is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine chetf2_rook(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void chetf2_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *zhetf2_rook*.

4.17.23 chfrk

Level 3 BLAS like routine for C in RFP Format.

chfrk performs one of the Hermitian rank–k operations

```
C := alpha*A*A**H + beta*C,
```

or

```
C := alpha*A**H*A + beta*C,
```

where alpha and beta are real scalars, C is an n–by–n Hermitian matrix and A is an n–by–k matrix in the first case and a k–by–n matrix in the second case.

Syntax

Fortran specification:

```
use armpl_library

subroutine chfrk(TRANSR, UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C)
```

C specification:

```
#include "armpl.h"

void chfrk_(const char *transr, const char *uplo, const char *trans,
            const armpl_int_t *n, const armpl_int_t *k, const float *alpha,
            const armpl_singlecomplex_t *a, const armpl_int_t *lda,
            const float *beta, armpl_singlecomplex_t *c, ... );
```

Parameters

TRANSR Input parameter.

TRANSR is CHARACTER*1

= 'N': The Normal Form of RFP A is stored; = 'C': The Conjugate-transpose Form of RFP A is stored.

UPLO Input parameter.

UPLO is CHARACTER*1

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANS Input parameter.

TRANS is CHARACTER*1

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' C := alpha*A*A^H + beta*C.

TRANS = 'C' or 'c' C := alpha*A^H * A + beta*C.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K Input parameter.

K is INTEGER

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA,ka). where KA is K when TRANS = 'N' or 'n', and is N otherwise. Before entry with TRANS = 'N' or 'n', the leading N–by–K part of the array A must contain the matrix A, otherwise the leading K–by–N part of the array A must contain the matrix A. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. Unchanged on exit.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (N*(N+1)/2). On entry, the matrix A in RFP Format. RFP Format is described by TRANSR, UPLO and N. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Related Information

For this routine in other precisions, please see *zhfrk*. It also exists with a native C interface as *LAPACKE_chfrk*.

4.17.24 cla_gbamv

CLA_GBAMV performs one of the matrix-vector operations

```
      y := alpha*abs(A)*abs(x) + beta*abs(y),
or    y := alpha*abs(A)**T*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_gbamv(TRANS, M, N, KL, KU, ALPHA, AB, LDAB, X, INCX, BETA, Y,
                     INCY)
```

C specification:

```
#include "armpl.h"

void cla_gbamv_(const armpl_int_t *trans, const armpl_int_t *m,
                const armpl_int_t *n, const armpl_int_t *kl,
                const armpl_int_t *ku, const float *alpha,
                const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
                const armpl_singlecomplex_t *x, const armpl_int_t *incx,
                const float *beta, float *y, const armpl_int_t *incy);
```

Parameters

TRANS Input parameter.

TRANS is INTEGER

On entry, TRANS specifies the operation to be performed as follows:

BLAS_NO_TRANS y := alpha*abs(A)*abs(x) + beta*abs(y) BLAS_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y) BLAS_CONJ_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y)

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB,n). Before entry, the leading m by n part of the array AB must contain the matrix of coefficients. Unchanged on exit.

LDAB Input parameter.

LDAB is INTEGER

On entry, LDAB specifies the first dimension of AB as declared in the calling (sub) program. LDAB must be at least max(1, m). Unchanged on exit.

X Input parameter.

X is COMPLEX

X is an array, dimension. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is REAL

Y is an array, dimension. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Level 2 Blas routine.

Related Information

For this routine in other precisions, please see *dla_gbamv*, *sla_gbamv* and *zla_gbamv*.

4.17.25 cla_gbrcond_c

```
CLA_GBRCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a REAL vector.
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_gbrcond_c(TRANS, N, KL, KU, AB, LDAB, AFB, LDAFB, IPIV, C,
                            CAPPLY, INFO, WORK, RWORK)
```

C specification:

```
#include "armpl.h"

float cla_gbrcond_c_(const char *trans, const armpl_int_t *n,
                     const armpl_int_t *kl, const armpl_int_t *ku,
                     const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
                     const armpl_singlecomplex_t *afb,
                     const armpl_int_t *ldafb, const armpl_int_t *ipiv,
                     const float *c, const armpl_int_t *capply,
                     armpl_int_t *info, const armpl_singlecomplex_t *work,
                     const float *rwork, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by CGBTRF; row i of the matrix was interchanged with row IPIV(i).

C Input parameter.

C is REAL

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is REAL

RWORK is an array, dimension (N).. Workspace.

Related Information

4.17.26 cla_gbrcond_x

```
CLA_GBRCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX vector.
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_gbrcond_x(TRANS, N, KL, KU, AB, LDAB, AFB, LDAFB, IPIV, X,
                            INFO, WORK, RWORK)
```

C specification:

```
#include "armpl.h"

float cla_gbrcond_x_(const char *trans, const armpl_int_t *n,
                     const armpl_int_t *kl, const armpl_int_t *ku,
                     const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
                     const armpl_singlecomplex_t *afb,
                     const armpl_int_t *ldafb, const armpl_int_t *ipiv,
                     const armpl_singlecomplex_t *x, armpl_int_t *info,
                     const armpl_singlecomplex_t *work, const float *rwork,
                     ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by CGBTRF; row i of the matrix was interchanged with row IPIV(i).

X Input parameter.

X is COMPLEX

X is an array, dimension (N). The vector X in the formula op(A) * diag(X).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is REAL

RWORK is an array, dimension (N).. Workspace.

4.17.27 cla_gbrfsx_extended

cla_gbrfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by CGBRFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_gbrfsx_extended(PREC_TYPE, TRANS_TYPE, N, KL, KU, NRHS, AB,
                               LDAB, AFB, LDAFB, IPIV, COLEQU, C, B, LDB, Y,
                               LDY, BERR_OUT, N_NORMS, ERR_BNDS_NORM,
                               ERR_BNDS_COMP, RES, AYB, DY, Y_TAIL, RCOND,
                               ITHRESH, RTHRESH, DZ_UB, IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void cla_gbrfsx_extended_(const armpl_int_t *prec_type,
                          const armpl_int_t *trans_type, const armpl_int_t *n,
                          const armpl_int_t *kl, const armpl_int_t *ku,
                          const armpl_int_t *nrhs,
                          const armpl_singlecomplex_t *ab,
                          const armpl_int_t *ldab,
                          const armpl_singlecomplex_t *afb,
                          const armpl_int_t *ldafb, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const float *c,
                          const armpl_singlecomplex_t *b,
                          const armpl_int_t *ldb, armpl_singlecomplex_t *y,
                          const armpl_int_t *ldy, float *berr_out,
                          const armpl_int_t *n_norms, float *err_bnds_norm,
                          float *err_bnds_comp, armpl_singlecomplex_t *res,
                          float *ayb, armpl_singlecomplex_t *dy,
                          armpl_singlecomplex_t *y_tail, const float *rcond,
                          const armpl_int_t *ithresh, const float *rthresh,
                          const float *dz_ub, const armpl_int_t *ignore_cwise,
                          armpl_int_t *info);
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

TRANS_TYPE Input parameter.

TRANS_TYPE is INTEGER

Specifies the transposition operation on A. The value is defined by ILATRANS(T) where T is a CHARACTER and T = 'N': No transpose = 'T': Transpose = 'C': Conjugate transpose

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the N-by-N matrix AB.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= max(1, N).

AFB Input parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by CGBTRF.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by CGBTRF; row i of the matrix was interchanged with row IPIV(i).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by CGBTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is REAL

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s)

)(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by CLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is REAL

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is REAL

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to CGBTRS had an illegal value

Related Information

4.17.28 cla_gbrpvgrw

CLA_GBRPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

real function cla_gbrpvgrw(N, KL, KU, NCOLS, AB, LDAB, AFB, LDAFB)
```

C specification:

```
#include "armpl.h"

float cla_gbrpvgrw_(const armpl_int_t *n, const armpl_int_t *kl,
                    const armpl_int_t *ku, const armpl_int_t *ncols,
                    const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
                    const armpl_singlecomplex_t *afb,
                    const armpl_int_t *ldafb);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

AFB Input parameter.

AFB is COMPLEX

AFB is an array, dimension (LDAFB, N). Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAFB Input parameter.

LDAFB is INTEGER

The leading dimension of the array AFB. LDAFB >= 2*KL+KU+1.

Related Information

For this routine in other precisions, please see *dla_gbrpvgrw*, *sla_gbrpvgrw* and *zla_gbrpvgrw*.

4.17.29 cla_geamv

CLA_GEAMV performs one of the matrix-vector operations

```
      y := alpha*abs(A)*abs(x) + beta*abs(y),
or    y := alpha*abs(A)**T*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_geamv(TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void cla_geamv_(const armpl_int_t *trans, const armpl_int_t *m,
                const armpl_int_t *n, const float *alpha,
                const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                const armpl_singlecomplex_t *x, const armpl_int_t *incx,
                const float *beta, float *y, const armpl_int_t *incy);
```

Parameters

TRANS Input parameter.

TRANS is INTEGER

On entry, TRANS specifies the operation to be performed as follows:

BLAS_NO_TRANS y := alpha*abs(A)*abs(x) + beta*abs(y) BLAS_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y) BLAS_CONJ_TRANS y := alpha*abs(A^T)*abs(x) + beta*abs(y)

Unchanged on exit.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is REAL

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA,n). Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, m). Unchanged on exit.

X Input parameter.

X is COMPLEX

X is an array, dimension. (1 + (n - 1)*abs(INCX)) when TRANS = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is REAL

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is REAL

Y is an array, dimension. (1 + (m - 1)*abs(INCY)) when TRANS = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Level 2 Blas routine.

Related Information

For this routine in other precisions, please see *dla_geamv*, *sla_geamv* and *zla_geamv*.

4.17.30 cla_gercond_c

```
CLA_GERCOND_C computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a REAL vector.
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_gercond_c(TRANS, N, A, LDA, AF, LDAF, IPIV, C, CAPPLY, INFO,
                            WORK, RWORK)
```

C specification:

```
#include "armpl.h"

float cla_gercond_c_(const char *trans, const armpl_int_t *n,
                     const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                     const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
                     const armpl_int_t *ipiv, const float *c,
                     const armpl_int_t *capply, armpl_int_t *info,
                     const armpl_singlecomplex_t *work, const float *rwork,
                     ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by CGETRF; row i of the matrix was interchanged with row IPIV(i).

C Input parameter.

C is REAL

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is REAL

RWORK is an array, dimension (N).. Workspace.

Related Information

4.17.31 cla_gercond_x

```
CLA_GERCOND_X computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX vector.
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_gercond_x(TRANS, N, A, LDA, AF, LDAF, IPIV, X, INFO, WORK,
                            RWORK)
```

C specification:

```
#include "armpl.h"

float cla_gercond_x_(const char *trans, const armpl_int_t *n,
                     const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                     const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
                     const armpl_int_t *ipiv, const armpl_singlecomplex_t *x,
                     armpl_int_t *info, const armpl_singlecomplex_t *work,
                     const float *rwork, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the form of the system of equations: = 'N': A * X = B (No transpose) = 'T': A^T * X = B (Transpose) = 'C': A^H * X = B (Conjugate Transpose = Transpose)

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by CGETRF; row i of the matrix was interchanged with row IPIV(i).

X Input parameter.

X is COMPLEX

X is an array, dimension (N). The vector X in the formula op(A) * diag(X).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is REAL

RWORK is an array, dimension (N).. Workspace.

4.17.32 cla_gerfsx_extended

cla_gerfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by CGERFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERRS_N and ERRS_C for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERRS_N and ERRS_C.

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_gerfsx_extended(PREC_TYPE, TRANS_TYPE, N, NRHS, A, LDA, AF,
                               LDAF, IPIV, COLEQU, C, B, LDB, Y, LDY,
                               BERR_OUT, N_NORMS, ERRS_N, ERRS_C, RES, AYB,
                               DY, Y_TAIL, RCOND, ITHRESH, RTHRESH, DZ_UB,
                               IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void cla_gerfsx_extended_(const armpl_int_t *prec_type,
                          const armpl_int_t *trans_type, const armpl_int_t *n,
                          const armpl_int_t *nrhs,
                          const armpl_singlecomplex_t *a,
                          const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                        const armpl_singlecomplex_t *af,
                        const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                        const armpl_int_t *colequ, const float *c,
                        const armpl_singlecomplex_t *b,
                        const armpl_int_t *ldb, armpl_singlecomplex_t *y,
                        const armpl_int_t *ldy, float *berr_out,
                        const armpl_int_t *n_norms, float *errs_n,
                        float *errs_c, armpl_singlecomplex_t *res,
                        float *ayb, armpl_singlecomplex_t *dy,
                        armpl_singlecomplex_t *y_tail, const float *rcond,
                        const armpl_int_t *ithresh, const float *rthresh,
                        const float *dz_ub, const armpl_int_t *ignore_cwise,
                        armpl_int_t *info);
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

TRANS_TYPE Input parameter.

TRANS_TYPE is INTEGER

Specifies the transposition operation on A. The value is defined by ILATRANS(T) where T is a CHARACTER and T = 'N': No transpose = 'T': Transpose = 'C': Conjugate transpose

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

The pivot indices from the factorization A = P*L*U as computed by CGETRF; row i of the matrix was interchanged with row IPIV(i).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by CGETRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is REAL

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by CLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERRS_N and ERRS_C). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERRS_N Input and output parameter.

ERRS_N is REAL

ERRS_N is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERRS_N(i,:) corresponds to the ith right-hand side.

The second index in ERRS_N(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERRS_C Input and output parameter.

ERRS_C is REAL

ERRS_C is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERRS_C is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERRS_C(i,:) corresponds to the ith right-hand side.

The second index in ERRS_C(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERRS_N and ERRS_C may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is REAL

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is REAL

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to CGETRS had an illegal value

Related Information

4.17.33 cla_gerpvgrw

CLA_GERPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The “max absolute element” norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

real function cla_gerpvgrw(N, NCOLS, A, LDA, AF, LDAF)
```

C specification:

```
#include "armpl.h"

float cla_gerpvgrw_(const armpl_int_t *n, const armpl_int_t *ncols,
                    const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                    const armpl_singlecomplex_t *af,
                    const armpl_int_t *ldaf);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

Related Information

For this routine in other precisions, please see *dla_gerpvgrw*, *sla_gerpvgrw* and *zla_gerpvgrw*.

4.17.34 cla_heamv

CLA_SYAMV performs the matrix-vector operation

```
y := alpha*abs(A)*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an n by n symmetric matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_heamv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void cla_heamv_(const armpl_int_t *uplo, const armpl_int_t *n,
                const float *alpha, const armpl_singlecomplex_t *a,
                const armpl_int_t *lda, const armpl_singlecomplex_t *x,
                const armpl_int_t *incx, const float *beta, float *y,
                const armpl_int_t *incy);
```

Parameters

UPLO Input parameter.

UPLO is INTEGER

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = BLAS_UPPER Only the upper triangular part of A is to be referenced.

UPLO = BLAS_LOWER Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is REAL .

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, n).. Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n). Unchanged on exit.

X Input parameter.

X is COMPLEX

X is an array, dimension. (1 + (n - 1)*abs(INCX)) Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is REAL .

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is REAL

Y is an array, dimension. (1 + (n - 1)*abs(INCY)) Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Related Information

For this routine in other precisions, please see *zla_heamv*.

4.17.35 cla_hercond_c

```
CLA_HERCOND_C computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a REAL vector.
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_hercond_c(UPLO, N, A, LDA, AF, LDAF, IPIV, C, CAPPLY, INFO,
                            WORK, RWORK)
```

C specification:

```
#include "armpl.h"

float cla_hercond_c_(const char *uplo, const armpl_int_t *n,
                     const armpl_singlecomplex_t *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                    const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
                    const armpl_int_t *ipiv, const float *c,
                    const armpl_int_t *capply, armpl_int_t *info,
                    const armpl_singlecomplex_t *work, const float *rwork,
                    ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

C Input parameter.

C is REAL

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is REAL

RWORK is an array, dimension (N).. Workspace.

Related Information

For this routine in other precisions, please see *zla_hercond_c*.

4.17.36 cla_hercond_x

```
CLA_HERCOND_X computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX vector.
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_hercond_x(UPLO, N, A, LDA, AF, LDAF, IPIV, X, INFO, WORK,
                            RWORK)
```

                          float *ayb, armpl_singlecomplex_t *dy,
                          armpl_singlecomplex_t *y_tail, const float *rcond,
                          const armpl_int_t *ithresh, const float *rthresh,
                          const float *dz_ub, const armpl_int_t *ignore_cwise,
                          armpl_int_t *info, ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by CHETRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is REAL

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by CLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix

Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is REAL

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is REAL

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to CLA_HERFSX_EXTENDED had an illegal value

Related Information

For this routine in other precisions, please see *zla_herfsx_extended*.

4.17.38 cla_herpvgrw

CLA_HERPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

real function cla_herpvgrw(UPLO, N, INFO, A, LDA, AF, LDAF, IPIV, WORK)
```

C specification:

```
#include "armpl.h"

float cla_herpvgrw_(const char *uplo, const armpl_int_t *n,
                    const armpl_int_t *info, const armpl_singlecomplex_t *a,
                    const armpl_int_t *lda, const armpl_singlecomplex_t *af,
                    const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                    float *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

INFO Input parameter.

INFO is INTEGER

The value of INFO returned from SSYTRF, .i.e., the pivot in column INFO is exactly 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CHETRF.

WORK Input parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *zla_herpvgrw*.

4.17.39 cla_lin_berr

```
CLA_LIN_BERR computes componentwise relative backward error from
   the formula
       max(i) ( abs(R(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
   where abs(Z) is the componentwise absolute value of the matrix
   or vector Z.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_lin_berr(N, NZ, NRHS, RES, AYB, BERR)
```

C specification:

```
#include "armpl.h"

void cla_lin_berr_(const armpl_int_t *n, const armpl_int_t *nz,
                   const armpl_int_t *nrhs, const armpl_singlecomplex_t *res,
                   const float *ayb, float *berr);
```

Parameters

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NZ Input parameter.

NZ is INTEGER

We add (NZ+1)*SLAMCH('Safe minimum') to R(i) in the numerator to guard against spuriously zero residuals. Default value is N.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices AYB, RES, and BERR. NRHS >= 0.

RES Input parameter.

RES is COMPLEX

RES is an array, dimension (N, NRHS). The residual matrix, i.e., the matrix R in the relative backward error formula above.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N, NRHS). The denominator in the relative backward error formula above, i.e., the matrix abs(op(A_s))*abs(Y) + abs(B_s). The matrices A, Y, and B are from iterative refinement (see cla_gerfsx_extended.f).

BERR Output parameter.

BERR is REAL

BERR is an array, dimension (NRHS). The componentwise relative backward error from the formula above.

Related Information

For this routine in other precisions, please see *dla_lin_berr*, *sla_lin_berr* and *zla_lin_berr*.

4.17.40 cla_porcond_c

```
CLA_PORCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a REAL vector
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_porcond_c(UPLO, N, A, LDA, AF, LDAF, C, CAPPLY, INFO, WORK,
                            RWORK)
```

C specification:

```
#include "armpl.h"

float cla_porcond_c_(const char *uplo, const armpl_int_t *n,
                     const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                     const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
                     const float *c, const armpl_int_t *capply,
                     armpl_int_t *info, const armpl_singlecomplex_t *work,
                     const float *rwork, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by CPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

C Input parameter.

C is REAL

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is REAL

RWORK is an array, dimension (N).. Workspace.

Related Information

For this routine in other precisions, please see *zla_porcond_c*.

4.17.41 cla_porcond_x

```
CLA_PORCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX vector.
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_porcond_x(UPLO, N, A, LDA, AF, LDAF, X, INFO, WORK, RWORK)
```

C specification:

```
#include "armpl.h"

float cla_porcond_x_(const char *uplo, const armpl_int_t *n,
                     const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                     const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
                     const armpl_singlecomplex_t *x, armpl_int_t *info,
                     const armpl_singlecomplex_t *work, const float *rwork,
                     ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H , as computed by CPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

X Input parameter.

X is COMPLEX

X is an array, dimension (N). The vector X in the formula op(A) * diag(X).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is REAL

RWORK is an array, dimension (N).. Workspace.

Related Information

For this routine in other precisions, please see *zla_porcond_x*.

4.17.42 cla_porfsx_extended

cla_porfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by CPORFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_porfsx_extended(PREC_TYPE, UPLO, N, NRHS, A, LDA, AF, LDAF,
                               COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS,
                               ERR_BNDS_NORM, ERR_BNDS_COMP, RES, AYB, DY,
                               Y_TAIL, RCOND, ITHRESH, RTHRESH, DZ_UB,
                               IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void cla_porfsx_extended_(const armpl_int_t *prec_type, const char *uplo,
                          const armpl_int_t *n, const armpl_int_t *nrhs,
                          const armpl_singlecomplex_t *a,
                          const armpl_int_t *lda,
                          const armpl_singlecomplex_t *af,
                          const armpl_int_t *ldaf, const armpl_int_t *colequ,
                          const float *c, const armpl_singlecomplex_t *b,
                          const armpl_int_t *ldb, armpl_singlecomplex_t *y,
                          const armpl_int_t *ldy, float *berr_out,
                          const armpl_int_t *n_norms, float *err_bnds_norm,
                          float *err_bnds_comp, armpl_singlecomplex_t *res,
                          float *ayb, armpl_singlecomplex_t *dy,
                          armpl_singlecomplex_t *y_tail, const float *rcond,
                          const armpl_int_t *ithresh, const float *rthresh,
                          const float *dz_ub, const armpl_int_t *ignore_cwise,
                          armpl_int_t *info, ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = 'S': Single = 'D': Double = 'I': Indigenous = 'X', 'E': Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by CPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by CPOTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is REAL

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by CLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 “Trust/don’t trust” boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch(‘Epsilon’).

err = 2 “Guaranteed” error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch(‘Epsilon’). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch(‘Epsilon’) to determine if the error estimate is “guaranteed”. These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is REAL

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is REAL

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to CPOTRS had an illegal value

Related Information

4.17.43 cla_porpvgrw

CLA_PORPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

real function cla_porpvgrw(UPLO, NCOLS, A, LDA, AF, LDAF, WORK)
```

C specification:

```
#include "armpl.h"

float cla_porpvgrw_(const char *uplo, const armpl_int_t *ncols,
                    const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                    const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
                    float *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

NCOLS Input parameter.

NCOLS is INTEGER

The number of columns of the matrix A. NCOLS >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA,N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1,N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF,N). The triangular factor U or L from the Cholesky factorization A = U^T *U or A = L*L^T , as computed by CPOTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1,N).

WORK Input parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *dla_porpvgrw*, *sla_porpvgrw* and *zla_porpvgrw*.

4.17.44 cla_syamv

CLA_SYAMV performs the matrix-vector operation

```
y := alpha*abs(A)*abs(x) + beta*abs(y),
```

where alpha and beta are scalars, x and y are vectors and A is an n by n symmetric matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, components in the resulting vector are perturbed away from zero by (N+1) times the underflow threshold. To prevent unnecessarily large errors for block-structure embedded in general matrices, "symbolically" zero components are not perturbed. A zero entry is considered "symbolic" if all multiplications involved in computing that entry have at least one zero multiplicand.

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_syamv(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

C specification:

```
#include "armpl.h"

void cla_syamv_(const armpl_int_t *uplo, const armpl_int_t *n,
                const float *alpha, const armpl_singlecomplex_t *a,
                const armpl_int_t *lda, const armpl_singlecomplex_t *x,
                const armpl_int_t *incx, const float *beta, float *y,
                const armpl_int_t *incy);
```

Parameters

UPLO Input parameter.

UPLO is INTEGER

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = BLAS_UPPER Only the upper triangular part of A is to be referenced.

UPLO = BLAS_LOWER Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

ALPHA Input parameter.

ALPHA is REAL .

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, n).. Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA Input parameter.

LDA is INTEGER

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least max(1, n). Unchanged on exit.

X Input parameter.

X is COMPLEX

X is an array, dimension. (1 + (n - 1)*abs(INCX)) Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX Input parameter.

INCX is INTEGER

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA Input parameter.

BETA is REAL .

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y Input and output parameter.

Y is REAL

Y is an array, dimension. (1 + (n - 1)*abs(INCY)) Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY Input parameter.

INCY is INTEGER

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Related Information

4.17.45 cla_syrcond_c

```
CLA_SYRCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a REAL vector.
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_syrcond_c(UPLO, N, A, LDA, AF, LDAF, IPIV, C, CAPPLY, INFO,
                            WORK, RWORK)
```

C specification:

```
#include "armpl.h"

float cla_syrcond_c_(const char *uplo, const armpl_int_t *n,
                     const armpl_singlecomplex_t *a, const armpl_int_t *lda,
```

(continues on next page)

(continued from previous page)

```
                    const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
                    const armpl_int_t *ipiv, const float *c,
                    const armpl_int_t *capply, armpl_int_t *info,
                    const armpl_singlecomplex_t *work, const float *rwork,
                    ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF.

C Input parameter.

C is REAL

C is an array, dimension (N). The vector C in the formula op(A) * inv(diag(C)).

CAPPLY Input parameter.

CAPPLY is LOGICAL

If .TRUE. then access the vector C in the formula above.

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is REAL

RWORK is an array, dimension (N).. Workspace.

Related Information

For this routine in other precisions, please see *zla_syrcond_c*.

4.17.46 cla_syrcond_x

```
CLA_SYRCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX vector.
```

Syntax

Fortran specification:

```
use armpl_library

real function cla_syrcond_x(UPLO, N, A, LDA, AF, LDAF, IPIV, X, INFO, WORK,
                            RWORK)
```

C specification:

```
#include "armpl.h"

float cla_syrcond_x_(const char *uplo, const armpl_int_t *n,
                     const armpl_singlecomplex_t *a, const armpl_int_t *lda,
                     const armpl_singlecomplex_t *af, const armpl_int_t *ldaf,
                     const armpl_int_t *ipiv, const armpl_singlecomplex_t *x,
                     armpl_int_t *info, const armpl_singlecomplex_t *work,
                     const float *rwork, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF.

X Input parameter.

X is COMPLEX

X is an array, dimension (N). The vector X in the formula op(A) * diag(X).

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. i > 0: The ith argument is invalid.

WORK Input parameter.

WORK is COMPLEX

WORK is an array, dimension (2*N).. Workspace.

RWORK Input parameter.

RWORK is REAL

RWORK is an array, dimension (N).. Workspace.

4.17.47 cla_syrfsx_extended

cla_syrfsx_extended improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. This subroutine is called by CSYRFSX to perform iterative refinement. In addition to normwise error bound, the code provides maximum componentwise error bound if possible. See comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds. Note that this subroutine is only resonsible for setting the second fields of ERR_BNDS_NORM and ERR_BNDS_COMP.

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_syrfsx_extended(PREC_TYPE, UPLO, N, NRHS, A, LDA, AF, LDAF,
                               IPIV, COLEQU, C, B, LDB, Y, LDY, BERR_OUT,
                               N_NORMS, ERR_BNDS_NORM, ERR_BNDS_COMP, RES,
                               AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
                               DZ_UB, IGNORE_CWISE, INFO)
```

C specification:

```
#include "armpl.h"

void cla_syrfsx_extended_(const armpl_int_t *prec_type, const char *uplo,
                          const armpl_int_t *n, const armpl_int_t *nrhs,
                          const armpl_singlecomplex_t *a,
                          const armpl_int_t *lda,
                          const armpl_singlecomplex_t *af,
                          const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                          const armpl_int_t *colequ, const float *c,
                          const armpl_singlecomplex_t *b,
                          const armpl_int_t *ldb, armpl_singlecomplex_t *y,
                          const armpl_int_t *ldy, float *berr_out,
                          const armpl_int_t *n_norms, float *err_bnds_norm,
                          float *err_bnds_comp, armpl_singlecomplex_t *res,
                          float *ayb, armpl_singlecomplex_t *dy,
                          armpl_singlecomplex_t *y_tail, const float *rcond,
                          const armpl_int_t *ithresh, const float *rthresh,
                          const float *dz_ub, const armpl_int_t *ignore_cwise,
                          armpl_int_t *info, ... );
```

Parameters

PREC_TYPE Input parameter.

PREC_TYPE is INTEGER

Specifies the intermediate precision to be used in refinement. The value is defined by ILAPREC(P) where P is a CHARACTER and P = ‘S’: Single = ‘D’: Double = ‘I’: Indigenous = ‘X’, ‘E’: Extra

UPLO Input parameter.

UPLO is CHARACTER*1

= ‘U’: Upper triangle of A is stored; = ‘L’: Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right-hand-sides, i.e., the number of columns of the matrix B.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF.

COLEQU Input parameter.

COLEQU is LOGICAL

If .TRUE. then column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A. If COLEQU = .FALSE., C is not accessed. If C is input, each element of C should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). The right-hand-side matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (LDY, NRHS). On entry, the solution matrix X, as computed by CSYTRS. On exit, the improved solution matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

BERR_OUT Output parameter.

BERR_OUT is REAL

BERR_OUT is an array, dimension (NRHS). On exit, BERR_OUT(j) contains the componentwise relative backward error for right-hand-side j from the formula max(i) (abs(RES(i)) / (abs(op(A_s))*abs(Y) + abs(B_s))(i)) where abs(Z) is the componentwise absolute value of the matrix or vector Z. This is computed by CLA_LIN_BERR.

N_NORMS Input parameter.

N_NORMS is INTEGER

Determines which error bounds to return (see ERR_BNDS_NORM and ERR_BNDS_COMP). If N_NORMS >= 1 return normwise error bounds. If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM Input and output parameter.

ERR_BNDS_NORM is REAL

ERR_BNDS_NORM is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the ith solution vector: max_j (abs(XTRUE(j,i) - X(j,i))) ——————————— max_j abs(X(j,i))

The array is indexed by the type of error information as described below. There currently are up to three pieces of information returned.

The first index in ERR_BNDS_NORM(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_NORM(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated normwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z. Let Z = S*A, where S scales each row by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP Input and output parameter.

ERR_BNDS_COMP is REAL

ERR_BNDS_COMP is an array, dimension (NRHS, N_ERR_BNDS). For each right-hand side, this array contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the ith solution vector: abs(XTRUE(j,i) - X(j,i)) max_j ——————————- abs(X(j,i))

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields: err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix

Z. Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above. See Lapack Working Note 165 for further details and extra cautions.

RES Input parameter.

RES is COMPLEX

RES is an array, dimension (N). Workspace to hold the intermediate residual.

AYB Input parameter.

AYB is REAL

AYB is an array, dimension (N). Workspace.

DY Input parameter.

DY is COMPLEX

DY is an array, dimension (N). Workspace to hold the intermediate solution.

Y_TAIL Input parameter.

Y_TAIL is COMPLEX

Y_TAIL is an array, dimension (N). Workspace to hold the trailing bits of the intermediate solution.

RCOND Input parameter.

RCOND is REAL

Reciprocal scaled condition number. This is an estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If this is less than the machine precision (in particular, if it is zero), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill- conditioned.

ITHRESH Input parameter.

ITHRESH is INTEGER

The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive' set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH Input parameter.

RTHRESH is REAL

Determines when to stop refinement if the error estimate stops decreasing. Refinement will stop when the next solution no longer satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices. See LAWN 165 for more details.

DZ_UB Input parameter.

DZ_UB is REAL

Determines when to start considering componentwise convergence. Componentwise convergence is only considered after each component of the solution Y is stable, which we definte as the relative change in each component being less than DZ_UB. The default value is 0.25, requiring the first bit to be stable. See LAWN 165 for more details.

IGNORE_CWISE Input parameter.

IGNORE_CWISE is LOGICAL

If .TRUE. then ignore componentwise convergence. Default value is .FALSE..

INFO Output parameter.

INFO is INTEGER

= 0: Successful exit. < 0: if INFO = -i, the ith argument to CLA_SYRFSX_EXTENDED had an illegal value

Related Information

For this routine in other precisions, please see *dla_syrfsx_extended*, *sla_syrfsx_extended* and *zla_syrfsx_extended*.

4.17.48 cla_syrpvgrw

CLA_SYRPVGRW computes the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, estimated condition numbers, and error bounds could be unreliable.

Syntax

Fortran specification:

```
use armpl_library

real function cla_syrpvgrw(UPLO, N, INFO, A, LDA, AF, LDAF, IPIV, WORK)
```

C specification:

```
#include "armpl.h"

float cla_syrpvgrw_(const char *uplo, const armpl_int_t *n,
                    const armpl_int_t *info, const armpl_singlecomplex_t *a,
                    const armpl_int_t *lda, const armpl_singlecomplex_t *af,
                    const armpl_int_t *ldaf, const armpl_int_t *ipiv,
                    float *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

N Input parameter.

N is INTEGER

The number of linear equations, i.e., the order of the matrix A. N >= 0.

INFO Input parameter.

INFO is INTEGER

The value of INFO returned from CSYTRF, .i.e., the pivot in column INFO is exactly 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the N-by-N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

AF Input parameter.

AF is COMPLEX

AF is an array, dimension (LDAF, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDAF Input parameter.

LDAF is INTEGER

The leading dimension of the array AF. LDAF >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF.

WORK Input parameter.

WORK is REAL

WORK is an array, dimension (2*N) .

Related Information

For this routine in other precisions, please see *dla_syrpvgrw*, *sla_syrpvgrw* and *zla_syrpvgrw*.

4.17.49 cla_wwaddw

```
CLA_WWADDW adds a vector W into a doubled-single vector (X, Y).

   This works for all extant IBM's hex and binary floating point
   arithmetics, but not for decimal.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine cla_wwaddw(N, X, Y, W)
```

C specification:

```
#include "armpl.h"

void cla_wwaddw_(const armpl_int_t *n, armpl_singlecomplex_t *x,
                 armpl_singlecomplex_t *y, const armpl_singlecomplex_t *w);
```

Parameters

N Input parameter.

N is INTEGER

The length of vectors X, Y, and W.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (N). The first part of the doubled-single accumulation vector.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (N). The second part of the doubled-single accumulation vector.

W Input parameter.

W is COMPLEX

W is an array, dimension (N). The vector to be added.

Related Information

For this routine in other precisions, please see *dla_wwaddw*, *sla_wwaddw* and *zla_wwaddw*.

4.17.50 clabrd

clabrd reduces the first NB rows and columns of a complex general m by n matrix A to upper or lower real bidiagonal form by a unitary transformation $Q^H * A * P$, and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A.

If m >= n, A is reduced to upper bidiagonal form; if m < n, to lower bidiagonal form.

This is an auxiliary routine called by CGEBRD

Syntax

Fortran specification:

```
use armpl_library

subroutine clabrd(M, N, NB, A, LDA, D, E, TAUQ, TAUP, X, LDX, Y, LDY)
```

C specification:

```
#include "armpl.h"

void clabrd_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *nb, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, float *d, float *e,
             armpl_singlecomplex_t *tauq, armpl_singlecomplex_t *taup,
             armpl_singlecomplex_t *x, const armpl_int_t *ldx,
             armpl_singlecomplex_t *y, const armpl_int_t *ldy);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows in the matrix A.

N Input parameter.

N is INTEGER

The number of columns in the matrix A.

NB Input parameter.

NB is INTEGER

The number of leading rows and columns of A to be reduced.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the m by n general matrix to be reduced. On exit, the first NB rows and columns of the matrix are overwritten; the rest of the array is unchanged. If m >= n, elements on and below the diagonal in the first NB columns, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first NB rows, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. If m < n, elements below the diagonal in the first NB columns, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first NB rows, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

D Output parameter.

D is REAL

D is an array, dimension (NB). The diagonal elements of the first NB rows and columns of the reduced matrix. D(i) = A(i,i).

E Output parameter.

E is REAL

E is an array, dimension (NB). The off-diagonal elements of the first NB rows and columns of the reduced matrix.

TAUQ Output parameter.

TAUQ is COMPLEX

TAUQ is an array, dimension (NB). The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP Output parameter.

TAUP is COMPLEX

TAUP is an array, dimension (NB). The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

X Output parameter.

X is COMPLEX

X is an array, dimension (LDX, NB). The m-by-nb matrix X required to update the unreduced part of A.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(1, M).

Y Output parameter.

Y is COMPLEX

Y is an array, dimension (LDY, NB). The n-by-nb matrix Y required to update the unreduced part of A.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= max(1, N).

Related Information

For this routine in other precisions, please see *dlabrd*, *slabrd* and *zlabrd*.

4.17.51 clacgv

clacgv conjugates a complex vector of length N.

Syntax

Fortran specification:

```
use armpl_library

subroutine clacgv(N, X, INCX)
```

C specification:

```
#include "armpl.h"

void clacgv_(const armpl_int_t *n, armpl_singlecomplex_t *x,
             const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vector X. N >= 0.

X Input and output parameter.

X is COMPLEX

X is an array, dimension. (1+(N-1)*abs(INCX)) On entry, the vector of length N to be conjugated. On exit, X is overwritten with conjg(X).

INCX Input parameter.

INCX is INTEGER

The spacing between successive elements of X.

Related Information

For this routine in other precisions, please see *zlacgv*. It also exists with a native C interface as *LAPACKE_clacgv*.

4.17.52 clacn2

clacn2 estimates the 1-norm of a square, complex matrix A. Reverse communication is used for evaluating matrix-vector products.

Syntax

Fortran specification:

```
use armpl_library

subroutine clacn2(N, V, X, EST, KASE, ISAVE)
```

C specification:

```
#include "armpl.h"

void clacn2_(const armpl_int_t *n, armpl_singlecomplex_t *v,
             armpl_singlecomplex_t *x, float *est, armpl_int_t *kase,
             armpl_int_t *isave);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 1.

V Output parameter.

V is COMPLEX

V is an array, dimension (N). On the final return, V = A*W, where EST = norm(V)/norm(W) (W is not returned).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (N). On an intermediate return, X should be overwritten by A * X, if KASE=1, A^H * X, if KASE=2, where A^H is the conjugate transpose of A, and CLACN2 must be re-called with all the other parameters unchanged.

EST Input and output parameter.

EST is REAL

On entry with KASE = 1 or 2 and ISAVE(1) = 3, EST should be unchanged from the previous call to CLACN2. On exit, EST is an estimate (a lower bound) for norm(A).

KASE Input and output parameter.

KASE is INTEGER

On the initial call to CLACN2, KASE should be 0. On an intermediate return, KASE will be 1 or 2, indicating whether X should be overwritten by A * X or A^H * X. On the final return from CLACN2, KASE will again be 0.

ISAVE Input and output parameter.

ISAVE is INTEGER array, dimension (3)

ISAVE is used to save variables between calls to SLACN2

Related Information

For this routine in other precisions, please see *dlacn2*, *slacn2* and *zlacn2*. It also exists with a native C interface as *LAPACKE_clacn2*.

4.17.53 clacon

`clacon` estimates the 1-norm of a square, complex matrix A. Reverse communication is used for evaluating matrix-vector products.

Syntax

Fortran specification:

```
use armpl_library

subroutine clacon(N, V, X, EST, KASE)
```

C specification:

```
#include "armpl.h"

void clacon_(const armpl_int_t *n, armpl_singlecomplex_t *v,
             armpl_singlecomplex_t *x, float *est, armpl_int_t *kase);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 1.

V Output parameter.

V is COMPLEX

V is an array, dimension (N). On the final return, V = A*W, where EST = norm(V)/norm(W) (W is not returned).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (N). On an intermediate return, X should be overwritten by A * X, if KASE=1, A^H * X, if KASE=2, where A^H is the conjugate transpose of A, and CLACON must be re-called with all the other parameters unchanged.

EST Input and output parameter.

EST is REAL

On entry with KASE = 1 or 2 and JUMP = 3, EST should be unchanged from the previous call to CLACON. On exit, EST is an estimate (a lower bound) for norm(A).

KASE Input and output parameter.

KASE is INTEGER

On the initial call to CLACON, KASE should be 0. On an intermediate return, KASE will be 1 or 2, indicating whether X should be overwritten by A * X or A^H * X. On the final return from CLACON, KASE will again be 0.

Related Information

For this routine in other precisions, please see *dlacon*, *slacon* and *zlacon*.

4.17.54 clacp2

`clacp2` copies all or part of a real two-dimensional matrix A to a complex matrix B.

Syntax

Fortran specification:

```
use armpl_library

subroutine clacp2(UPLO, M, N, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void clacp2_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const float *a, const armpl_int_t *lda, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be copied to B. = 'U': Upper triangular part = 'L': Lower triangular part Otherwise: All of the matrix A

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, N). The m by n matrix A. If UPLO = 'U', only the upper trapezium is accessed; if UPLO = 'L', only the lower trapezium is accessed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On exit, B = A in the locations specified by UPLO.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

Related Information

For this routine in other precisions, please see *zlacp2*. It also exists with a native C interface as *LAPACKE_clacp2*.

4.17.55 clacpy

clacpy copies all or part of a two-dimensional matrix A to another matrix B.

Syntax

Fortran specification:

```
use armpl_library

subroutine clacpy(UPLO, M, N, A, LDA, B, LDB)
```

C specification:

```
#include "armpl.h"

void clacpy_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be copied to B. = 'U': Upper triangular part = 'L': Lower triangular part Otherwise: All of the matrix A

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The m by n matrix A. If UPLO = 'U', only the upper trapezium is accessed; if UPLO = 'L', only the lower trapezium is accessed.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

B Output parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On exit, B = A in the locations specified by UPLO.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, M).

Related Information

For this routine in other precisions, please see *dlacpy*, *slacpy* and *zlacpy*. It also exists with a native C interface as *LAPACKE_clacpy*.

4.17.56 clacrm

clacrm performs a very simple matrix-matrix multiplication:

```
C := A * B,
```

where A is M by N and complex; B is N by N and real; C is M by N and complex.

Syntax

Fortran specification:

```
use armpl_library

subroutine clacrm(M, N, A, LDA, B, LDB, C, LDC, RWORK)
```

C specification:

```
#include "armpl.h"

void clacrm_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             const float *b, const armpl_int_t *ldb, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, float *rwork);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A and of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns and rows of the matrix B and the number of columns of the matrix C. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, A contains the M by N matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >=max(1, M).

B Input parameter.

B is REAL

B is an array, dimension (LDB, N). On entry, B contains the N by N matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >=max(1, N).

C Output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On exit, C contains the M by N matrix C.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >=max(1, N).

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*M*N) .

Related Information

For this routine in other precisions, please see *zlacrm*. It also exists with a native C interface as *LAPACKE_clacrm*.

4.17.57 clacrt

clacrt performs the operation

```
(  c  s )( x )  ==> ( x )
( -s  c )( y )      ( y )
```

where c and s are complex and the vectors x and y are complex.

Syntax

Fortran specification:

```
use armpl_library

subroutine clacrt(N, CX, INCX, CY, INCY, C, S)
```

C specification:

```
#include "armpl.h"

void clacrt_(const armpl_int_t *n, armpl_singlecomplex_t *cx,
             const armpl_int_t *incx, armpl_singlecomplex_t *cy,
             const armpl_int_t *incy, const armpl_singlecomplex_t *c,
             const armpl_singlecomplex_t *s);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements in the vectors CX and CY.

CX Input and output parameter.

CX is COMPLEX

CX is an array, dimension (N). On input, the vector x. On output, CX is overwritten with c*x + s*y.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of CX. INCX <> 0.

CY Input and output parameter.

CY is COMPLEX

CY is an array, dimension (N). On input, the vector y. On output, CY is overwritten with -s*x + c*y.

INCY Input parameter.

INCY is INTEGER

The increment between successive values of CY. INCY <> 0.

C Input parameter.

C is COMPLEX

S Input parameter.

S is COMPLEX

C and S define the matrix [C S]. [-S C]

Related Information

For this routine in other precisions, please see *zlacrt*.

4.17.58 cladiv

cladiv := X / Y, where X and Y are complex. The computation of X / Y will not overflow on an intermediary step unless the results overflows.

Syntax

Fortran specification:

```
use armpl_library

complex function cladiv(X, Y)
```

C specification:

```
#include "armpl.h"

SINGLECOMPLEX_RET_VALUE cladiv_(SINGLECOMPLEX_RET_PARAM const armpl_singlecomplex_
↪t *x,
                                const armpl_singlecomplex_t *y);
```

Parameters

X Input parameter.

X is COMPLEX

Y Input parameter.

Y is COMPLEX

The complex scalars X and Y.

Related Information

For this routine in other precisions, please see *dladiv*, *sladiv* and *zladiv*.

4.17.59 claed0

Using the divide and conquer method, claed0 computes all eigenvalues of a symmetric tridiagonal matrix which is one diagonal block of those from reducing a dense or band Hermitian matrix and corresponding eigenvectors of the dense or band matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine claed0(QSIZ, N, D, E, Q, LDQ, QSTORE, LDQS, RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void claed0_(const armpl_int_t *qsiz, const armpl_int_t *n, float *d,
             float *e, armpl_singlecomplex_t *q, const armpl_int_t *ldq,
             armpl_singlecomplex_t *qstore, const armpl_int_t *ldqs,
             float *rwork, armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the unitary matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the diagonal elements of the tridiagonal matrix. On exit, the eigenvalues in ascending order.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). On entry, the off-diagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, Q must contain an QSIZ x N matrix whose columns unitarily orthonormal. It is a part of the unitary matrix that reduces the full dense Hermitian matrix to a (reducible) symmetric tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

IWORK Output parameter.

IWORK is INTEGER array,

the dimension of IWORK must be at least 6 + 6* N + 5*N*lg N (lg(N) = smallest integer k such that 2^k >= N)

RWORK Output parameter.

RWORK is REAL

RWORK is an array,. dimension (1 + 3* N + 2*N*lg N + 3*N**2) (lg(N) = smallest integer k such that 2^k >= N)

QSTORE Output parameter.

QSTORE is COMPLEX

QSTORE is an array, dimension (LDQS, N). Used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

LDQS Input parameter.

LDQS is INTEGER

The leading dimension of the array QSTORE. LDQS >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

Related Information

For this routine in other precisions, please see *dlaed0*, *slaed0* and *zlaed0*.

4.17.60 claed7

claed7 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and optionally eigenvectors of a dense or banded Hermitian matrix that has been reduced to tridiagonal form.

```
 T = Q(in) ( D(in) + RHO * Z*Z**H ) Q**H(in) = Q(out) * D(out) * Q**H(out)

where Z = Q**Hu, u is a vector of length N with ones in the
CUTPNT and CUTPNT + 1 th elements and zeros elsewhere.

 The eigenvectors of the original matrix are stored in Q, and the
 eigenvalues are in D.  The algorithm consists of three stages:

    The first stage consists of deflating the size of the problem
    when there are multiple eigenvalues or if there is a zero in
    the Z vector.  For each such occurrence the dimension of the
    secular equation problem is reduced by one.  This stage is
    performed by the routine SLAED2.

    The second stage consists of calculating the updated
    eigenvalues. This is done by finding the roots of the secular
    equation via the routine SLAED4 (as called by SLAED3).
    This routine also calculates the eigenvectors of the current
    problem.

    The final stage consists of computing the updated eigenvectors
    directly using the updated eigenvalues.  The eigenvectors for
    the current problem are multiplied with the eigenvectors from
    the overall problem.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine claed7(N, CUTPNT, QSIZ, TLVLS, CURLVL, CURPBM, D, Q, LDQ, RHO,
                  INDXQ, QSTORE, QPTR, PRMPTR, PERM, GIVPTR, GIVCOL, GIVNUM,
                  WORK, RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void claed7_(const armpl_int_t *n, const armpl_int_t *cutpnt,
             const armpl_int_t *qsiz, const armpl_int_t *tlvls,
             const armpl_int_t *curlvl, const armpl_int_t *curpbm, float *d,
             armpl_singlecomplex_t *q, const armpl_int_t *ldq,
             const float *rho, armpl_int_t *indxq, float *qstore,
             armpl_int_t *qptr, const armpl_int_t *prmptr,
             const armpl_int_t *perm, const armpl_int_t *givptr,
             const armpl_int_t *givcol, const float *givnum,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

CUTPNT Input parameter.

CUTPNT is INTEGER

Contains the location of the last eigenvalue in the leading sub-matrix. min(1, N) <= CUTPNT <= N.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the unitary matrix used to reduce the full matrix to tridiagonal form. QSIZ >= N.

TLVLS Input parameter.

TLVLS is INTEGER

The total number of merging levels in the overall divide and conquer tree.

CURLVL Input parameter.

CURLVL is INTEGER

The current level in the overall merge routine, 0 <= curlvl <= tlvls.

CURPBM Input parameter.

CURPBM is INTEGER

The current problem in the current level in the overall merge routine (counting from upper left to lower right).

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the eigenvalues of the rank-1-perturbed matrix. On exit, the eigenvalues of the repaired matrix.

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, the eigenvectors of the rank-1-perturbed matrix. On exit, the eigenvectors of the repaired tridiagonal matrix.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

RHO Input parameter.

RHO is REAL

Contains the subdiagonal element used to create the rank-1 modification.

INDXQ Output parameter.

INDXQ is INTEGER array, dimension (N)

This contains the permutation which will reintegrate the subproblem just solved back into sorted order, ie. D(INDXQ(I = 1, N)) will be in ascending order.

IWORK Output parameter.

IWORK is INTEGER array, dimension (4*N)

RWORK Output parameter.

RWORK is REAL

RWORK is an array,. dimension (3*N+2*QSIZ*N)

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (QSIZ*N) .

QSTORE Input and output parameter.

QSTORE is REAL

QSTORE is an array, dimension (N**2+1). Stores eigenvectors of submatrices encountered during divide and conquer, packed together. QPTR points to beginning of the submatrices.

QPTR Input and output parameter.

QPTR is INTEGER array, dimension (N+2)

List of indices pointing to beginning of submatrices stored in QSTORE. The submatrices are numbered starting at the bottom left of the divide and conquer tree, from left to right and bottom to top.

PRMPTR Input parameter.

PRMPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in PERM a level's permutation is stored. PRMPTR(i+1) - PRMPTR(i) indicates the size of the permutation and also the size of the full, non-deflated problem.

PERM Input parameter.

PERM is INTEGER array, dimension (N lg N)

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N lg N)

Contains a list of pointers which indicate where in GIVCOL a level's Givens rotations are stored. GIVPTR(i+1) - GIVPTR(i) indicates the number of Givens rotations.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (2, N lg N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Input parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (2, N lg N). Each number indicates the S value to be used in the corresponding Givens rotation.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: if INFO = 1, an eigenvalue did not converge

Related Information

For this routine in other precisions, please see *dlaed7*, *slaed7* and *zlaed7*.

4.17.61 claed8

claed8 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny element in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Syntax

Fortran specification:

```
use armpl_library

subroutine claed8(K, N, QSIZ, Q, LDQ, D, RHO, CUTPNT, Z, DLAMDA, Q2, LDQ2, W,
                  INDXP, INDX, INDXQ, PERM, GIVPTR, GIVCOL, GIVNUM, INFO)
```

C specification:

```
#include "armpl.h"

void claed8_(armpl_int_t *k, const armpl_int_t *n, const armpl_int_t *qsiz,
             armpl_singlecomplex_t *q, const armpl_int_t *ldq, float *d,
             float *rho, const armpl_int_t *cutpnt, const float *z,
             float *dlamda, armpl_singlecomplex_t *q2,
             const armpl_int_t *ldq2, float *w, armpl_int_t *indxp,
             armpl_int_t *indx, const armpl_int_t *indxq, armpl_int_t *perm,
             armpl_int_t *givptr, armpl_int_t *givcol, float *givnum,
             armpl_int_t *info);
```

Parameters

K Output parameter.

K is INTEGER

Contains the number of non-deflated eigenvalues. This is the order of the related secular equation.

N Input parameter.

N is INTEGER

The dimension of the symmetric tridiagonal matrix. N >= 0.

QSIZ Input parameter.

QSIZ is INTEGER

The dimension of the unitary matrix used to reduce the dense or band matrix to tridiagonal form. QSIZ >= N if ICOMPQ = 1.

Q Input and output parameter.

Q is COMPLEX

Q is an array, dimension (LDQ, N). On entry, Q contains the eigenvectors of the partially solved system which has been previously updated in matrix multiplies with other partially solved eigensystems. On exit, Q contains the trailing (N-K) updated eigenvectors (those which were deflated) in its last N-K columns.

LDQ Input parameter.

LDQ is INTEGER

The leading dimension of the array Q. LDQ >= max(1, N).

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, D contains the eigenvalues of the two submatrices to be combined. On exit, D contains the trailing (N-K) updated eigenvalues (those which were deflated) sorted into increasing order.

RHO Input and output parameter.

RHO is REAL

Contains the off diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined. RHO is modified during the computation to the value required by SLAED3.

CUTPNT Input parameter.

CUTPNT is INTEGER

Contains the location of the last eigenvalue in the leading sub-matrix. MIN(1, N) <= CUTPNT <= N.

Z Input parameter.

Z is REAL

Z is an array, dimension (N). On input this vector contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). The contents of Z are destroyed during the updating process.

DLAMDA Output parameter.

DLAMDA is REAL

DLAMDA is an array, dimension (N). Contains a copy of the first K eigenvalues which will be used by SLAED3 to form the secular equation.

Q2 Output parameter.

Q2 is COMPLEX

Q2 is an array, dimension (LDQ2, N). If ICOMPQ = 0, Q2 is not referenced. Otherwise, Contains a copy of the first K eigenvectors which will be used by SLAED7 in a matrix multiply (SGEMM) to update the new eigenvectors.

LDQ2 Input parameter.

LDQ2 is INTEGER

The leading dimension of the array Q2. LDQ2 >= max(1, N).

W Output parameter.

W is REAL

W is an array, dimension (N). This will hold the first k values of the final deflation-altered z-vector and will be passed to SLAED3.

INDXP Output parameter.

INDXP is INTEGER array, dimension (N)

This will contain the permutation used to place deflated values of D at the end of the array. On output INDXP(1:K) points to the nondeflated D-values and INDXP(K+1:N) points to the deflated eigenvalues.

INDX Output parameter.

INDX is INTEGER array, dimension (N)

This will contain the permutation used to sort the contents of D into ascending order.

INDXQ Input parameter.

INDXQ is INTEGER array, dimension (N)

This contains the permutation which separately sorts the two sub-problems in D into ascending order. Note that elements in the second half of this permutation must first have CUTPNT added to their values in order to be accurate.

PERM Output parameter.

PERM is INTEGER array, dimension (N)

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

GIVPTR Output parameter.

GIVPTR is INTEGER

Contains the number of Givens rotations which took place in this subproblem.

GIVCOL Output parameter.

GIVCOL is INTEGER array, dimension (2, N)

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

GIVNUM Output parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (2, N). Each number indicates the S value to be used in the corresponding Givens rotation.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dlaed8*, *slaed8* and *zlaed8*.

4.17.62 claein

claein uses inverse iteration to find a right or left eigenvector corresponding to the eigenvalue W of a complex upper Hessenberg matrix H.

Syntax

Fortran specification:

```
use armpl_library

subroutine claein(RIGHTV, NOINIT, N, H, LDH, W, V, B, LDB, RWORK, EPS3,
                  SMLNUM, INFO)
```

C specification:

```
#include "armpl.h"

void claein_(const armpl_int_t *rightv, const armpl_int_t *noinit,
             const armpl_int_t *n, const armpl_singlecomplex_t *h,
             const armpl_int_t *ldh, const armpl_singlecomplex_t *w,
             armpl_singlecomplex_t *v, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, float *rwork, const float *eps3,
             const float *smlnum, armpl_int_t *info);
```

Parameters

RIGHTV Input parameter.

RIGHTV is LOGICAL

= .TRUE. : compute right eigenvector; = .FALSE.: compute left eigenvector.

NOINIT Input parameter.

NOINIT is LOGICAL

= .TRUE. : no initial vector supplied in V = .FALSE.: initial vector supplied in V.

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

H Input parameter.

H is COMPLEX

H is an array, dimension (LDH, N). The upper Hessenberg matrix H.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

W Input parameter.

W is COMPLEX

The eigenvalue of H whose corresponding right or left eigenvector is to be computed.

V Input and output parameter.

V is COMPLEX

V is an array, dimension (N). On entry, if NOINIT = .FALSE., V must contain a starting vector for inverse iteration; otherwise V need not be set. On exit, V contains the computed eigenvector, normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x| + |y|.

B Output parameter.

B is COMPLEX

B is an array, dimension (LDB, N) .

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (N) .

EPS3 Input parameter.

EPS3 is REAL

A small machine-dependent value which is used to perturb close eigenvalues, and to replace zero pivots.

SMLNUM Input parameter.

SMLNUM is REAL

A machine-dependent value close to the underflow threshold.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit = 1: inverse iteration did not converge; V is set to the last iterate.

Related Information

For this routine in other precisions, please see *dlaein*, *slaein* and *zlaein*.

4.17.63 claesy

`claesy` computes the eigendecomposition of a 2-by-2 symmetric matrix

```
( ( A, B );( B, C ) )
```

provided the norm of the matrix of eigenvectors is larger than some threshold value.

RT1 is the eigenvalue of larger absolute value, and RT2 of smaller absolute value. If the eigenvectors are computed, then on return (CS1, SN1) is the unit eigenvector for RT1, hence

[CS1 SN1] . [A B] . [CS1 -SN1] = [RT1 0] [-SN1 CS1] [B C] [SN1 CS1] [0 RT2]

Syntax

Fortran specification:

```
use armpl_library

subroutine claesy(A, B, C, RT1, RT2, EVSCAL, CS1, SN1)
```

C specification:

```
#include "armpl.h"

void claesy_(const armpl_singlecomplex_t *a, const armpl_singlecomplex_t *b,
             const armpl_singlecomplex_t *c, armpl_singlecomplex_t *rt1,
             armpl_singlecomplex_t *rt2, armpl_singlecomplex_t *evscal,
             armpl_singlecomplex_t *cs1, armpl_singlecomplex_t *sn1);
```

Parameters

A Input parameter.

`A` is `COMPLEX`

The (1, 1) element of input matrix.

B Input parameter.

`B` is `COMPLEX`

The (1, 2) element of input matrix. The (2, 1) element is also given by `B`, since the 2-by-2 matrix is symmetric.

C Input parameter.

`C` is `COMPLEX`

The (2, 2) element of input matrix.

RT1 Output parameter.

`RT1` is `COMPLEX`

The eigenvalue of larger modulus.

RT2 Output parameter.

RT2 is COMPLEX

The eigenvalue of smaller modulus.

EVSCAL Output parameter.

EVSCAL is COMPLEX

The complex value by which the eigenvector matrix was scaled to make it orthonormal. If EVSCAL is zero, the eigenvectors were not computed. This means one of two things: the 2-by-2 matrix could not be diagonalized, or the norm of the matrix of eigenvectors before scaling was larger than the threshold value THRESH (set below).

CS1 Output parameter.

CS1 is COMPLEX

SN1 Output parameter.

SN1 is COMPLEX

If EVSCAL .NE. 0, (CS1, SN1) is the unit right eigenvector for RT1.

Related Information

For this routine in other precisions, please see *zlaesy*.

4.17.64 claev2

claev2 computes the eigendecomposition of a 2-by-2 Hermitian matrix

```
[  A          B  ]
[  CONJG(B)   C  ].
```

On return, RT1 is the eigenvalue of larger absolute value, RT2 is the eigenvalue of smaller absolute value, and (CS1,SN1) is the unit right eigenvector for RT1, giving the decomposition

[CS1 CONJG(SN1)] [A B] [CS1 -CONJG(SN1)] = [RT1 0] [-SN1 CS1] [CONJG(B) C] [SN1 CS1] [0 RT2].

Syntax

Fortran specification:

```
use armpl_library

subroutine claev2(A, B, C, RT1, RT2, CS1, SN1)
```

C specification:

```
#include "armpl.h"

void claev2_(const armpl_singlecomplex_t *a, const armpl_singlecomplex_t *b,
             const armpl_singlecomplex_t *c, float *rt1, float *rt2,
             float *cs1, armpl_singlecomplex_t *sn1);
```

Parameters

A Input parameter.

A is COMPLEX

The (1,1) element of the 2-by-2 matrix.

B Input parameter.

B is COMPLEX

The (1,2) element and the conjugate of the (2,1) element of the 2-by-2 matrix.

C Input parameter.

C is COMPLEX

The (2,2) element of the 2-by-2 matrix.

RT1 Output parameter.

RT1 is REAL

The eigenvalue of larger absolute value.

RT2 Output parameter.

RT2 is REAL

The eigenvalue of smaller absolute value.

CS1 Output parameter.

CS1 is REAL

SN1 Output parameter.

SN1 is COMPLEX

The vector (CS1, SN1) is a unit right eigenvector for RT1.

Related Information

For this routine in other precisions, please see *dlaev2*, *slaev2* and *zlaev2*.

4.17.65 clag2z

clag2z converts a COMPLEX matrix, SA, to a COMPLEX*16 matrix, A.

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is an auxiliary routine so there is no argument checking.

Syntax

Fortran specification:

```
use armpl_library

subroutine clag2z(M, N, SA, LDSA, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void clag2z_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_singlecomplex_t *sa, const armpl_int_t *ldsa,
             armpl_doublecomplex_t *a, const armpl_int_t *lda,
             armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of lines of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

SA Input parameter.

SA is COMPLEX

SA is an array, dimension (LDSA, N). On entry, the M-by-N coefficient matrix SA.

LDSA Input parameter.

LDSA is INTEGER

The leading dimension of the array SA. LDSA >= max(1, M).

A Output parameter.

A is COMPLEX*16

A is an array, dimension (LDA, N). On exit, the M-by-N coefficient matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

Related Information

It also exists with a native C interface as *LAPACKE_clag2z*.

4.17.66 clags2

clags2 computes 2-by-2 unitary matrices U, V and Q, such that if (UPPER) then

```
U**H *A*Q = U**H *( A1 A2 )*Q = ( x  0  )
                  ( 0  A3 )     ( x  x  )
```

and

```
V**H*B*Q = V**H *( B1 B2 )*Q = ( x  0  )
                 ( 0  B3 )     ( x  x  )
```

or if (.NOT.UPPER) then

```
U**H *A*Q = U**H *( A1 0  )*Q = ( x  x  )
                  ( A2 A3 )     ( 0  x  )
```

and

```
V**H *B*Q = V**H *( B1 0  )*Q = ( x  x  )
                  ( B2 B3 )     ( 0  x  )
```

where

```
U = (   CSU     SNU ), V = (  CSV     SNV ),
    ( -SNU**H   CSU )      ( -SNV**H CSV )

Q = (   CSQ     SNQ )
    ( -SNQ**H   CSQ )
```

The rows of the transformed A and B are parallel. Moreover, if the input 2-by-2 matrix A is not zero, then the transformed (1,1) entry of A is not zero. If the input matrices A and B are both not zero, then the transformed (2,2) element of B is not zero, except when the first rows of input A and B are parallel and the second rows are zero.

Syntax

Fortran specification:

```
use armpl_library

subroutine clags2(UPPER, A1, A2, A3, B1, B2, B3, CSU, SNU, CSV, SNV, CSQ,
                  SNQ)
```

C specification:

```
#include "armpl.h"

void clags2_(const armpl_int_t *upper, const float *a1,
             const armpl_singlecomplex_t *a2, const float *a3,
             const float *b1, const armpl_singlecomplex_t *b2,
             const float *b3, float *csu, armpl_singlecomplex_t *snu,
             float *csv, armpl_singlecomplex_t *snv, float *csq,
             armpl_singlecomplex_t *snq);
```

Parameters

UPPER Input parameter.

UPPER is LOGICAL

= .TRUE.: the input matrices A and B are upper triangular. = .FALSE.: the input matrices A and B are lower triangular.

A1 Input parameter.

A1 is REAL

A2 Input parameter.

A2 is COMPLEX

A3 Input parameter.

A3 is REAL

On entry, A1, A2 and A3 are elements of the input 2-by-2 upper (lower) triangular matrix A.

B1 Input parameter.

B1 is REAL

B2 Input parameter.

B2 is COMPLEX

B3 Input parameter.

B3 is REAL

On entry, B1, B2 and B3 are elements of the input 2-by-2 upper (lower) triangular matrix B.

CSU Output parameter.

CSU is REAL

SNU Output parameter.

SNU is COMPLEX

The desired unitary matrix U.

CSV Output parameter.

CSV is REAL

SNV Output parameter.

SNV is COMPLEX

The desired unitary matrix V.

CSQ Output parameter.

CSQ is REAL

SNQ Output parameter.

SNQ is COMPLEX

The desired unitary matrix Q.

Related Information

For this routine in other precisions, please see *dlags2*, *slags2* and *zlags2*.

4.17.67 clagtm

clagtm performs a matrix-vector product of the form

```
B := alpha * A * X + beta * B
```

where A is a tridiagonal matrix of order N, B and X are N by NRHS matrices, and alpha and beta are real scalars, each of which may be 0., 1., or -1.

Syntax

Fortran specification:

```
use armpl_library

subroutine clagtm(TRANS, N, NRHS, ALPHA, DL, D, DU, X, LDX, BETA, B, LDB)
```

C specification:

```
#include "armpl.h"

void clagtm_(const char *trans, const armpl_int_t *n, const armpl_int_t *nrhs,
             const float *alpha, const armpl_singlecomplex_t *dl,
             const armpl_singlecomplex_t *d, const armpl_singlecomplex_t *du,
             const armpl_singlecomplex_t *x, const armpl_int_t *ldx,
             const float *beta, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, ... );
```

Parameters

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': No transpose, B := alpha * A * X + beta * B = 'T': Transpose, B := alpha * A^T * X + beta * B = 'C': Conjugate transpose, B := alpha * A^H * X + beta * B

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrices X and B.

ALPHA Input parameter.

ALPHA is REAL

The scalar alpha. ALPHA must be 0., 1., or -1.; otherwise, it is assumed to be 0.

DL Input parameter.

DL is COMPLEX

DL is an array, dimension (N-1). The (n-1) sub-diagonal elements of T.

D Input parameter.

D is COMPLEX

D is an array, dimension (N). The diagonal elements of T.

DU Input parameter.

DU is COMPLEX

DU is an array, dimension (N-1). The (n-1) super-diagonal elements of T.

X Input parameter.

X is COMPLEX

X is an array, dimension (LDX, NRHS). The N by NRHS matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X. LDX >= max(N,1).

BETA Input parameter.

BETA is REAL

The scalar beta. BETA must be 0., 1., or -1.; otherwise, it is assumed to be 1.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the N by NRHS matrix B. On exit, B is overwritten by the matrix expression B := alpha * A * X + beta * B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(N,1).

Related Information

For this routine in other precisions, please see *dlagtm*, *slagtm* and *zlagtm*.

4.17.68 clahef

clahef computes a partial factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**H U22**H )
```

A = (L11 0) (D 0) ($L11^H$ $L21^H$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0      I     )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB. Note that U^H denotes the conjugate transpose of U.

clahef is an auxiliary routine called by CHETRF. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine clahef(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void clahef_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             armpl_int_t *kb, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv,
             armpl_singlecomplex_t *w, const armpl_int_t *ldw,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is COMPLEX

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *zlahef*.

4.17.69 clahef_aa

CLAHEF_AA factorizes a panel of a complex hermitian matrix A using the Aasen's algorithm. The panel consists of a set of NB rows of A when UPLO is U, or a set of NB columns when UPLO is L.

In order to factorize the panel, the Aasen's algorithm requires the last row, or column, of the previous panel. The first row, or column, of A is set to be the first row, or column, of an identity matrix, which is used to factorize the first panel.

The resulting J-th row of U, or J-th column of L, is stored in the (J-1)-th row, or column, of A (without the unit diagonals), while the diagonal and subdiagonal of A are overwritten by those of T.

Syntax

Fortran specification:

```
use armpl_library

subroutine clahef_aa(UPLO, J1, M, NB, A, LDA, IPIV, H, LDH, WORK)
```

C specification:

```
#include "armpl.h"

void clahef_aa_(const char *uplo, const armpl_int_t *j1, const armpl_int_t *m,
                const armpl_int_t *nb, armpl_singlecomplex_t *a,
                const armpl_int_t *lda, armpl_int_t *ipiv,
                armpl_singlecomplex_t *h, const armpl_int_t *ldh,
                armpl_singlecomplex_t *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

J1 Input parameter.

J1 is INTEGER

The location of the first row, or column, of the panel within the submatrix of A, passed to this routine, e.g., when called by CHETRF_AA, for the first panel, J1 is 1, while for the remaining panels, J1 is 2.

M Input parameter.

M is INTEGER

The dimension of the submatrix. M >= 0.

NB Input parameter.

NB is INTEGER

The dimension of the panel to be facotorized.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, M) for. the first panel, while dimension (LDA,M+1) for the remaining panels.

On entry, A contains the last row, or column, of the previous panel, and the trailing submatrix of A to be factorized, except for the first panel, only the panel is passed.

On exit, the leading panel is factorized.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1,N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the row and column interchanges, the row and column k were interchanged with the row and column IPIV(k).

H Input and output parameter.

H is COMPLEX workspace, dimension (LDH, NB).

LDH Input parameter.

LDH is INTEGER

The leading dimension of the workspace H. LDH >= max(1, M).

WORK Output parameter.

WORK is COMPLEX workspace, dimension (M).

Related Information

For this routine in other precisions, please see *zlahef_aa*.

4.17.70 clahef_rook

CLAHEF_ROOK computes a partial factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**H U22**H )
```

A = (L11 0) (D 0) ($L11^H$ $L21^H$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0      I     )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB. Note that U^H denotes the conjugate transpose of U.

CLAHEF_ROOK is an auxiliary routine called by CHETRF_ROOK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine clahef_rook(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void clahef_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nb, armpl_int_t *kb,
                  armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_singlecomplex_t *w,
                  const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is COMPLEX

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *zlahef_rook*.

4.17.71 clahqr

```
CLAHQR is an auxiliary routine called by CHSEQR to update the
   eigenvalues and Schur decomposition already computed by CHSEQR, by
   dealing with the Hessenberg submatrix in rows and columns ILO to
   IHI.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine clahqr(WANTT, WANTZ, N, ILO, IHI, H, LDH, W, ILOZ, IHIZ, Z, LDZ,
                  INFO)
```

C specification:

```
#include "armpl.h"

void clahqr_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_singlecomplex_t *h,
             const armpl_int_t *ldh, armpl_singlecomplex_t *w,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
```

(continues on next page)

(continued from previous page)

```
            armpl_singlecomplex_t *z, const armpl_int_t *ldz,
            armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N >= 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns IHI+1:N, and that H(ILO,ILO-1) = 0 (unless ILO = 1). CLAHQR works primarily with the Hessenberg submatrix in rows and columns ILO to IHI, but applies transformations to all of H if WANTT is .TRUE.. 1 <= ILO <= max(1, IHI); IHI <= N.

H Input and output parameter.

H is COMPLEX

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO is zero and if WANTT is .TRUE., then H is upper triangular in rows and columns ILO:IHI. If INFO is zero and if WANTT is .FALSE., then the contents of H are unspecified on exit. The output state of H in case INF is positive is below under the description of INFO.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH >= max(1, N).

W Output parameter.

W is COMPLEX

W is an array, dimension (N). The computed eigenvalues ILO to IHI are stored in the corresponding elements of W. If WANTT is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with W(i) = H(i,i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 <= ILOZ <= ILO; IHI <= IHIZ <= N.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). If WANTZ is .TRUE., on entry Z must contain the current matrix Z of transformations accumulated by CHSEQR, and on exit Z has been updated; transformations are applied only to the submatrix Z(ILOZ:IHIZ,ILO:IHI). If WANTZ is .FALSE., Z is not referenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: if INFO = i, CLAHQR failed to compute all the eigenvalues ILO to IHI in a total of 30 iterations per eigenvalue; elements i+1:ihi of W contain those eigenvalues which have been successfully computed.

If INFO .GT. 0 and WANTT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO thorugh INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit (*) (initial value of H)*U = U*(final value of H) where U is an orthognal matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit (final value of Z) = (initial value of Z)*U where U is the orthogonal matrix in (*) (regardless of the value of WANTT.)

Related Information

For this routine in other precisions, please see *dlahqr*, *slahqr* and *zlahqr*.

4.17.72 clahr2

clahr2 reduces the first NB columns of A complex general n-BY-(n-k+1) matrix A so that elements below the k-th subdiagonal are zero. The reduction is performed by an unitary similarity transformation Q^H * A * Q. The routine returns the matrices V and T which determine Q as a block reflector I - V*T*v^H , and also the matrix Y = A * V * T.

This is an auxiliary routine called by CGEHRD.

Syntax

Fortran specification:

```
use armpl_library

subroutine clahr2(N, K, NB, A, LDA, TAU, T, LDT, Y, LDY)
```

C specification:

```
#include "armpl.h"

void clahr2_(const armpl_int_t *n, const armpl_int_t *k,
             const armpl_int_t *nb, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *t, const armpl_int_t *ldt,
             armpl_singlecomplex_t *y, const armpl_int_t *ldy);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix A.

K Input parameter.

K is INTEGER

The offset for the reduction. Elements below the k-th subdiagonal in the first NB columns are reduced to zero. K < N.

NB Input parameter.

NB is INTEGER

The number of columns to be reduced.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA,N-K+1). On entry, the n-by-(n-k+1) general matrix A. On exit, the elements on and above the k-th subdiagonal in the first NB columns are overwritten with the corresponding elements of the reduced matrix; the elements below the k-th subdiagonal, with the array TAU, represent the matrix Q as a product of elementary reflectors. The other columns of A are unchanged. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (NB). The scalar factors of the elementary reflectors. See Further Details.

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, NB). The upper triangular matrix T.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

Y Output parameter.

Y is COMPLEX

Y is an array, dimension (LDY, NB). The n-by-nb matrix Y.

LDY Input parameter.

LDY is INTEGER

The leading dimension of the array Y. LDY >= N.

Related Information

For this routine in other precisions, please see *dlahr2*, *slahr2* and *zlahr2*.

4.17.73 claic1

`claic1` applies one step of incremental condition estimation in its simplest version:

Let x, twonorm(x) = 1, be an approximate singular vector of an j-by-j lower triangular matrix L, such that

```
twonorm(L*x) = sest
```

Then `claic1` computes sestpr, s, c such that the vector

```
       [ s*x ]
xhat = [  c  ]
```

is an approximate singular vector of

```
       [ L       0    ]
Lhat = [ w**H gamma ]
```

in the sense that

```
twonorm(Lhat*xhat) = sestpr.
```

Depending on JOB, an estimate for the largest or smallest singular value is computed.

Note that [s c]^H and sestpr**2 is an eigenpair of the system

```
diag(sest*sest, 0) + [alpha  gamma] * [ conjg(alpha) ]
                                      [ conjg(gamma) ]
```

where alpha = x^H *w.

Syntax

Fortran specification:

```
use armpl_library

subroutine claic1(JOB, J, X, SEST, W, GAMMA, SESTPR, S, C)
```

C specification:

```
#include "armpl.h"

void claic1_(const armpl_int_t *job, const armpl_int_t *j,
             const armpl_singlecomplex_t *x, const float *sest,
             const armpl_singlecomplex_t *w,
             const armpl_singlecomplex_t *gamma, float *sestpr,
             armpl_singlecomplex_t *s, armpl_singlecomplex_t *c);
```

Parameters

JOB Input parameter.

`JOB` is `INTEGER`

= 1: an estimate for the largest singular value is computed. = 2: an estimate for the smallest singular value is computed.

J Input parameter.

`J` is `INTEGER`

Length of `X` and `W`

X Input parameter.

X is COMPLEX

X is an array, dimension (J). The j-vector x.

SEST Input parameter.

SEST is REAL

Estimated singular value of j by j matrix L

W Input parameter.

W is COMPLEX

W is an array, dimension (J). The j-vector w.

GAMMA Input parameter.

GAMMA is COMPLEX

The diagonal element gamma.

SESTPR Output parameter.

SESTPR is REAL

Estimated singular value of (j+1) by (j+1) matrix Lhat.

S Output parameter.

S is COMPLEX

Sine needed in forming xhat.

C Output parameter.

C is COMPLEX

Cosine needed in forming xhat.

Related Information

For this routine in other precisions, please see *dlaic1*, *slaic1* and *zlaic1*.

4.17.74 clals0

clals0 applies back the multiplying factors of either the left or the right singular vector matrix of a diagonal matrix appended by a row to the right hand side matrix B in solving the least squares problem using the divide-and-conquer SVD approach.

For the left singular vector matrix, three types of orthogonal matrices are involved:

(1L) Givens rotations: the number of such rotations is GIVPTR; the

```
pairs of columns/rows they were applied to are stored in GIVCOL;
and the C- and S-values of these rotations are stored in GIVNUM.
```

(2L) Permutation. The (NL+1)-st row of B is to be moved to the first

```
row, and for J=2:N, PERM(J)-th row of B is to be moved to the
J-th row.
```

(3L) The left singular vector matrix of the remaining matrix.

For the right singular vector matrix, four types of orthogonal matrices are involved:

(1R) The right singular vector matrix of the remaining matrix.

(2R) If SQRE = 1, one extra Givens rotation to generate the right

```
null space.
```

(3R) The inverse transformation of (2L).

(4R) The inverse transformation of (1L).

Syntax

Fortran specification:

```
use armpl_library

subroutine clals0(ICOMPQ, NL, NR, SQRE, NRHS, B, LDB, BX, LDBX, PERM, GIVPTR,
                  GIVCOL, LDGCOL, GIVNUM, LDGNUM, POLES, DIFL, DIFR, Z, K, C,
                  S, RWORK, INFO)
```

C specification:

```
#include "armpl.h"

void clals0_(const armpl_int_t *icompq, const armpl_int_t *nl,
             const armpl_int_t *nr, const armpl_int_t *sqre,
             const armpl_int_t *nrhs, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *bx,
             const armpl_int_t *ldbx, const armpl_int_t *perm,
             const armpl_int_t *givptr, const armpl_int_t *givcol,
             const armpl_int_t *ldgcol, const float *givnum,
             const armpl_int_t *ldgnum, const float *poles, const float *difl,
             const float *difr, const float *z, const armpl_int_t *k,
             const float *c, const float *s, float *rwork,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether singular vectors are to be computed in factored form: = 0: Left singular vector matrix. = 1: Right singular vector matrix.

NL Input parameter.

NL is INTEGER

The row dimension of the upper block. NL >= 1.

NR Input parameter.

NR is INTEGER

The row dimension of the lower block. NR >= 1.

SQRE Input parameter.

SQRE is INTEGER

= 0: the lower block is an NR-by-NR square matrix. = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

The bidiagonal matrix has row dimension N = NL + NR + 1, and column dimension M = N + SQRE.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B and BX. NRHS must be at least 1.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem in rows 1 through M. On output, B contains the solution X in rows 1 through N.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B. LDB must be at least max(1,MAX(M, N)).

BX Output parameter.

BX is COMPLEX

BX is an array, dimension (LDBX, NRHS) .

LDBX Input parameter.

LDBX is INTEGER

The leading dimension of BX.

PERM Input parameter.

PERM is INTEGER array, dimension (N)

The permutations (from deflation and sorting) applied to the two blocks.

GIVPTR Input parameter.

GIVPTR is INTEGER

The number of Givens rotations which took place in this subproblem.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2)

Each pair of numbers indicates a pair of rows/columns involved in a Givens rotation.

LDGCOL Input parameter.

LDGCOL is INTEGER

The leading dimension of GIVCOL, must be at least N.

GIVNUM Input parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (LDGNUM, 2). Each number indicates the C or S value used in the corresponding Givens rotation.

LDGNUM Input parameter.

LDGNUM is INTEGER

The leading dimension of arrays DIFR, POLES and GIVNUM, must be at least K.

POLES Input parameter.

POLES is REAL

POLES is an array, dimension (LDGNUM, 2). On entry, POLES(1:K, 1) contains the new singular values obtained from solving the secular equation, and POLES(1:K, 2) is an array containing the poles in the secular equation.

DIFL Input parameter.

DIFL is REAL

DIFL is an array, dimension (K).. On entry, DIFL(I) is the distance between I-th updated (undeflated) singular value and the I-th (undeflated) old singular value.

DIFR Input parameter.

DIFR is REAL

DIFR is an array, dimension (LDGNUM, 2).. On entry, DIFR(I, 1) contains the distances between I-th updated (undeflated) singular value and the I+1-th (undeflated) old singular value. And DIFR(I, 2) is the normalizing factor for the I-th right singular vector.

Z Input parameter.

Z is REAL

Z is an array, dimension (K). Contain the components of the deflation-adjusted updating row vector.

K Input parameter.

K is INTEGER

Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. 1 <= K <=N.

C Input parameter.

C is REAL

C contains garbage if SQRE =0 and the C-value of a Givens rotation related to the right null space if SQRE = 1.

S Input parameter.

S is REAL

S contains garbage if SQRE =0 and the S-value of a Givens rotation related to the right null space if SQRE = 1.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension. (K*(1+NRHS) + 2* NRHS)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dlals0*, *slals0* and *zlals0*.

4.17.75 clalsa

clalsa is an itermediate step in solving the least squares problem by computing the SVD of the coefficient matrix in compact form (The singular vectors are computed as products of simple orthorgonal matrices.).

If ICOMPQ = 0, clalsa applies the inverse of the left singular vector matrix of an upper bidiagonal matrix to the right hand side; and if ICOMPQ = 1, clalsa applies the right singular vector matrix to the right hand side. The singular vector matrices were generated in compact form by clalsa.

Syntax

Fortran specification:

```
use armpl_library

subroutine clalsa(ICOMPQ, SMLSIZ, N, NRHS, B, LDB, BX, LDBX, U, LDU, VT, K,
                  DIFL, DIFR, Z, POLES, GIVPTR, GIVCOL, LDGCOL, PERM, GIVNUM,
                  C, S, RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void clalsa_(const armpl_int_t *icompq, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *nrhs,
             armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             armpl_singlecomplex_t *bx, const armpl_int_t *ldbx,
             const float *u, const armpl_int_t *ldu, const float *vt,
             const armpl_int_t *k, const float *difl, const float *difr,
             const float *z, const float *poles, const armpl_int_t *givptr,
             const armpl_int_t *givcol, const armpl_int_t *ldgcol,
             const armpl_int_t *perm, const float *givnum, const float *c,
             const float *s, float *rwork, armpl_int_t *iwork,
             armpl_int_t *info);
```

Parameters

ICOMPQ Input parameter.

ICOMPQ is INTEGER

Specifies whether the left or the right singular vector matrix is involved. = 0: Left singular vector matrix = 1: Right singular vector matrix

SMLSIZ Input parameter.

SMLSIZ is INTEGER

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

N is INTEGER

The row and column dimensions of the upper bidiagonal matrix.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B and BX. NRHS must be at least 1.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem in rows 1 through M. On output, B contains the solution X in rows 1 through N.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B in the calling subprogram. LDB must be at least max(1,MAX(M, N)).

BX Output parameter.

BX is COMPLEX

BX is an array, dimension (LDBX, NRHS). On exit, the result of applying the left or right singular vector matrix to B.

LDBX Input parameter.

LDBX is INTEGER

The leading dimension of BX.

U Input parameter.

U is REAL

U is an array, dimension (LDU, SMLSIZ).. On entry, U contains the left singular vector matrices of all subproblems at the bottom level.

LDU Input parameter.

LDU is INTEGER, LDU = > N.

The leading dimension of arrays U, VT, DIFL, DIFR, POLES, GIVNUM, and Z.

VT Input parameter.

VT is REAL

VT is an array, dimension (LDU, SMLSIZ+1).. On entry, VT^H contains the right singular vector matrices of all subproblems at the bottom level.

K Input parameter.

K is INTEGER array, dimension (N).

DIFL Input parameter.

DIFL is REAL

DIFL is an array, dimension (LDU, NLVL).. where NLVL = INT(log_2 (N/(SMLSIZ+1))) + 1.

DIFR Input parameter.

DIFR is REAL

DIFR is an array, dimension (LDU, 2 * NLVL).. On entry, DIFL(*, I) and DIFR(*, 2 * I -1) record distances between singular values on the I-th level and singular values on the (I -1)-th level, and DIFR(*, 2 * I) record the normalizing factors of the right singular vectors matrices of subproblems on I-th level.

Z Input parameter.

Z is REAL

Z is an array, dimension (LDU, NLVL).. On entry, Z(1, I) contains the components of the deflation- adjusted updating row vector for subproblems on the I-th level.

POLES Input parameter.

POLES is REAL

POLES is an array, dimension (LDU, 2 * NLVL).. On entry, POLES(*, 2 * I -1: 2 * I) contains the new and old singular values involved in the secular equations on the I-th level.

GIVPTR Input parameter.

GIVPTR is INTEGER array, dimension (N).

On entry, GIVPTR(I) records the number of Givens rotations performed on the I-th problem on the computation tree.

GIVCOL Input parameter.

GIVCOL is INTEGER array, dimension (LDGCOL, 2 * NLVL).

On entry, for each I, GIVCOL(*, 2 * I - 1: 2 * I) records the locations of Givens rotations performed on the I-th level on the computation tree.

LDGCOL Input parameter.

LDGCOL is INTEGER, LDGCOL = > N.

The leading dimension of arrays GIVCOL and PERM.

PERM Input parameter.

PERM is INTEGER array, dimension (LDGCOL, NLVL).

On entry, PERM(*, I) records permutations done on the I-th level of the computation tree.

GIVNUM Input parameter.

GIVNUM is REAL

GIVNUM is an array, dimension (LDU, 2 * NLVL).. On entry, GIVNUM(*, 2 *I -1 : 2 * I) records the C- and S- values of Givens rotations performed on the I-th level on the computation tree.

C Input parameter.

C is REAL

C is an array, dimension (N).. On entry, if the I-th subproblem is not square, C(I) contains the C-value of a Givens rotation related to the right null space of the I-th subproblem.

S Input parameter.

S is REAL

S is an array, dimension (N).. On entry, if the I-th subproblem is not square, S(I) contains the S-value of a Givens rotation related to the right null space of the I-th subproblem.

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension at least. MAX((SMLSZ+1)*NRHS*3, N*(1+NRHS) + 2* NRHS).

IWORK Output parameter.

IWORK is INTEGER array, dimension (3*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dlalsa*, *slalsa* and *zlalsa*.

4.17.76 clalsd

clalsd uses the singular value decomposition of A to solve the least squares problem of finding X to minimize the Euclidean norm of each column of A*X-B, where A is N-by-N upper bidiagonal, and X and B are N-by-NRHS. The solution X overwrites B.

The singular values of A smaller than RCOND times the largest singular value are treated as zero in solving the least squares problem; in this case a minimum norm solution is returned. The actual singular values are returned in D in ascending order.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Syntax

Fortran specification:

```
use armpl_library

subroutine clalsd(UPLO, SMLSIZ, N, NRHS, D, E, B, LDB, RCOND, RANK, WORK,
                  RWORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void clalsd_(const char *uplo, const armpl_int_t *smlsiz,
             const armpl_int_t *n, const armpl_int_t *nrhs, float *d,
             float *e, armpl_singlecomplex_t *b, const armpl_int_t *ldb,
             const float *rcond, armpl_int_t *rank,
             armpl_singlecomplex_t *work, float *rwork, armpl_int_t *iwork,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': D and E define an upper bidiagonal matrix. = 'L': D and E define a lower bidiagonal matrix.

SMLSIZ Input parameter.

SMLSIZ is INTEGER

The maximum size of the subproblems at the bottom of the computation tree.

N Input parameter.

N is INTEGER

The dimension of the bidiagonal matrix. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of columns of B. NRHS must be at least 1.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry D contains the main diagonal of the bidiagonal matrix. On exit, if INFO = 0, D contains its singular values.

E Input and output parameter.

E is REAL

E is an array, dimension (N-1). Contains the super-diagonal entries of the bidiagonal matrix. On exit, E has been destroyed.

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On input, B contains the right hand sides of the least squares problem. On output, B contains the solution X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of B in the calling subprogram. LDB must be at least max(1, N).

RCOND Input parameter.

RCOND is REAL

The singular values of A less than or equal to RCOND times the largest singular value are treated as zero in solving the least squares problem. If RCOND is negative, machine precision is used instead. For example, if diag(S)*X=B were the least squares problem, where diag(S) is a diagonal matrix of singular values, the solution would be X(i) = B(i) / S(i) if S(i) is greater than RCOND*max(S), and X(i) = 0 if S(i) is less than or equal to RCOND*max(S).

RANK Output parameter.

RANK is INTEGER

The number of singular values of A greater than RCOND times the largest singular value.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N * NRHS). .

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension at least. (9* N + 2*N* SMLSIZ + 8*N*NLVL + 3*SMLSIZ* NRHS + MAX((SMLSIZ+1)**2, N*(1+NRHS) + 2* NRHS), where NLVL = MAX(0, INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1)

IWORK Output parameter.

IWORK is INTEGER array, dimension (3*N*NLVL + 11*N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit. < 0: if INFO = -i, the i-th argument had an illegal value. > 0: The algorithm failed to compute a singular value while working on the submatrix lying in rows and columns INFO/(N+1) through MOD(INFO,N+1).

4.17.77 clamswlq

CLAMQRTS overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'T': Q^H * C C * Q^H where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by short wide LQ factorization (CLASWLQ)

Syntax

Fortran specification:

```
use armpl_library

subroutine clamswlq(SIDE, TRANS, M, N, K, MB, NB, A, LDA, T, LDT, C, LDC,
                    WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void clamswlq_(const char *side, const char *trans, const armpl_int_t *m,
               const armpl_int_t *n, const armpl_int_t *k,
               const armpl_int_t *mb, const armpl_int_t *nb,
               armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_singlecomplex_t *t, const armpl_int_t *ldt,
               armpl_singlecomplex_t *c, const armpl_int_t *ldc,
               armpl_singlecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix C. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. N >= M.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0;

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. M >= MB >= 1

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. NB > M.

NB Input parameter.

NB is INTEGER

The block size to be used in the blocked QR. MB > M.

A Input parameter.

A is COMPLEX

A is an array, dimension. (LDA, M) if SIDE = 'L', (LDA, N) if SIDE = 'R' The i-th row must contain the vector which defines the blocked elementary reflector H(i), for i = 1,2,...,k, as returned by CLASWLQ in the first k rows of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is COMPLEX

T is an array, dimension. (M * Number of blocks(CEIL(N-K/NB-K)), The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) COMPLEX

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1, NB) * MB; if SIDE = 'R', LWORK >= max(1, M) * MB. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dlamswlq*, *slamswlq* and *zlamswlq*.

4.17.78 clamtsqr

CLAMTSQR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': Q * C C * Q TRANS = 'C': Q^H * C C * Q^H where Q is a real orthogonal matrix defined as the product of blocked elementary reflectors computed by tall skinny QR factorization (CLATSQR)

Syntax

Fortran specification:

```
use armpl_library

subroutine clamtsqr(SIDE, TRANS, M, N, K, MB, NB, A, LDA, T, LDT, C, LDC,
                    WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void clamtsqr_(const char *side, const char *trans, const armpl_int_t *m,
               const armpl_int_t *n, const armpl_int_t *k,
               const armpl_int_t *mb, const armpl_int_t *nb,
               armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_singlecomplex_t *t, const armpl_int_t *ldt,
               armpl_singlecomplex_t *c, const armpl_int_t *ldc,
               armpl_singlecomplex_t *work, const armpl_int_t *lwork,
               armpl_int_t *info, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right.

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': No transpose, apply Q; = 'C': Conjugate Transpose, apply Q^H .

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >=0.

N Input parameter.

N is INTEGER

The number of columns of the matrix C. M >= N >= 0.

K Input parameter.

K is INTEGER

The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0;

MB Input parameter.

MB is INTEGER

The block size to be used in the blocked QR. MB > N. (must be the same as DLATSQR)

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. N >= NB >= 1.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, K). The i-th column must contain the vector which defines the blockedelementary reflector H(i), for i = 1,2,...,k, as returned by DLATSQR in the first k columns of its array argument A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If SIDE = 'L', LDA >= max(1, M); if SIDE = 'R', LDA >= max(1, N).

T Input parameter.

T is COMPLEX

T is an array, dimension. (N * Number of blocks(CEIL(M-K/MB-K)), The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See below for further details.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by Q* C or Q^H * C or C*Q^H or C*Q.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

(workspace) COMPLEX

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK.

If SIDE = 'L', LWORK >= max(1, N)*NB; if SIDE = 'R', LWORK >= max(1, MB)*NB. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dlamtsqr*, *slamtsqr* and *zlamtsqr*.

4.17.79 clangb

clangb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n band matrix A, with kl sub-diagonals and ku super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

real function clangb(NORM, N, KL, KU, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

float clangb_(const char *norm, const armpl_int_t *n, const armpl_int_t *kl,
              const armpl_int_t *ku, const armpl_singlecomplex_t *ab,
              const armpl_int_t *ldab, float *work, ... );
```

Returns

CLANGB = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANGB as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANGB is set to zero.

KL Input parameter.

KL is INTEGER

The number of sub-diagonals of the matrix A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of super-diagonals of the matrix A. KU >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KL+KU+1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlangb*, *slangb* and *zlangb*.

4.17.80 clange

clange returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function clange(NORM, M, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

float clange_(const char *norm, const armpl_int_t *m, const armpl_int_t *n,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              float *work, ... );
```

Returns

CLANGE = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANGE as described above.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0. When M = 0, CLANGE is set to zero.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0. When N = 0, CLANGE is set to zero.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The m by n matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlange*, *slange* and *zlange*. It also exists with a native C interface as *LAPACKE_clange*.

4.17.81 clangt

clangt returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function clangt(NORM, N, DL, D, DU)
```

C specification:

```
#include "armpl.h"

float clangt_(const char *norm, const armpl_int_t *n,
              const armpl_singlecomplex_t *dl, const armpl_singlecomplex_t *d,
              const armpl_singlecomplex_t *du, ... );
```

Returns

CLANGT = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANGT as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANGT is set to zero.

DL Input parameter.

DL is COMPLEX

DL is an array, dimension (N-1). The (n-1) sub-diagonal elements of A.

D Input parameter.

D is COMPLEX

D is an array, dimension (N). The diagonal elements of A.

DU Input parameter.

DU is COMPLEX

DU is an array, dimension (N-1). The (n-1) super-diagonal elements of A.

Related Information

For this routine in other precisions, please see *dlangt*, *slangt* and *zlangt*.

4.17.82 clanhb

clanhb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n hermitian band matrix A, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

real function clanhb(NORM, UPLO, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

float clanhb_(const char *norm, const char *uplo, const armpl_int_t *n,
              const armpl_int_t *k, const armpl_singlecomplex_t *ab,
              const armpl_int_t *ldab, float *work, ... );
```

Returns

CLANHB = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANHB as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the band matrix A is supplied. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANHB is set to zero.

K Input parameter.

K is INTEGER

The number of super-diagonals or sub-diagonals of the band matrix A. K >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The upper or lower triangle of the hermitian band matrix A, stored in the first K+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k). Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *zlanhb*.

4.17.83 clanhe

clanhe returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex hermitian matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function clanhe(NORM, UPLO, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

float clanhe_(const char *norm, const char *uplo, const armpl_int_t *n,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              float *work, ... );
```

Returns

CLANHE = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANHE as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the hermitian matrix A is to be referenced. = ‘U’: Upper triangular part of A is referenced = ‘L’: Lower triangular part of A is referenced

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANHE is set to zero.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The hermitian matrix A. If UPLO = ‘U’, the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = ‘L’, the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *zlanhe*. It also exists with a native C interface as *LAPACKE_clanhe*.

4.17.84 clanhf

clanhf returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A in RFP format.

Syntax

Fortran specification:

```
use armpl_library

real function clanhf(NORM, TRANSR, UPLO, N, A, WORK)
```

C specification:

```
#include "armpl.h"

float clanhf_(const char *norm, const char *transr, const char *uplo,
              const armpl_int_t *n, const armpl_singlecomplex_t *a,
              float *work, ... );
```

Returns

CLANHF = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER

Specifies the value to be returned in CLANHF as described above.

TRANSR Input parameter.

TRANSR is CHARACTER

Specifies whether the RFP format of A is normal or conjugate-transposed format. = 'N': RFP format is Normal = 'C': RFP format is Conjugate-transposed

UPLO Input parameter.

UPLO is CHARACTER

On entry, UPLO specifies whether the RFP matrix A came from an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' RFP A came from an upper triangular matrix

UPLO = 'L' or 'l' RFP A came from a lower triangular matrix

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANHF is set to zero.

A Input parameter.

A is COMPLEX

A is an array, dimension (N*(N+1)/2);. On entry, the matrix A in RFP Format. RFP Format is described by TRANSR, UPLO and N as follows: If TRANSR='N' then RFP A is (0:N,0:K-1) when N is even; K=N/2. RFP A is (0:N-1,0:K) when N is odd; K=N/2. If TRANSR = 'C' then RFP is the Conjugate-transpose of RFP A as defined when TRANSR = 'N'. The contents of RFP A are defined by UPLO as follows: If UPLO = 'U' the RFP A contains the (N*(N+1)/2) elements of upper packed A either in normal or conjugate-transpose Format. If UPLO = 'L' the RFP A contains the (N*(N+1) /2) elements of lower packed A either in normal or conjugate-transpose Format. The LDA of RFP A is (N+1)/2 when TRANSR = 'C'. When TRANSR is 'N' the LDA is N+1 when N is even and is N when is odd. See the Note below for more details. Unchanged on exit.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (LWORK),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *zlanhf*.

4.17.85 clanhp

clanhp returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex hermitian matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

real function clanhp(NORM, UPLO, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

float clanhp_(const char *norm, const char *uplo, const armpl_int_t *n,
              const armpl_singlecomplex_t *ap, float *work, ... );
```

Returns

CLANHP = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANHP as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the hermitian matrix A is supplied. = 'U': Upper triangular part of A is supplied = 'L': Lower triangular part of A is supplied

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANHP is set to zero.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *zlanhp*.

4.17.86 clanhs

clanhs returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hessenberg matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function clanhs(NORM, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

float clanhs_(const char *norm, const armpl_int_t *n,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              float *work, ... );
```

Returns

CLANHS = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANHS as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANHS is set to zero.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The n by n upper Hessenberg matrix A; the part of A below the first sub-diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlanhs*, *slanhs* and *zlanhs*.

4.17.87 clanht

clanht returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian tridiagonal matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function clanht(NORM, N, D, E)
```

C specification:

```
#include "armpl.h"

float clanht_(const char *norm, const armpl_int_t *n, const float *d,
              const armpl_singlecomplex_t *e, ... );
```

Returns

CLANHT = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANHT as described above.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANHT is set to zero.

D Input parameter.

D is REAL

D is an array, dimension (N). The diagonal elements of A.

E Input parameter.

E is COMPLEX

E is an array, dimension (N-1). The (n-1) sub-diagonal or super-diagonal elements of A.

Related Information

For this routine in other precisions, please see *zlanht*.

4.17.88 clansb

clansb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n symmetric band matrix A, with k super-diagonals.

Syntax

Fortran specification:

```
use armpl_library

real function clansb(NORM, UPLO, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

float clansb_(const char *norm, const char *uplo, const armpl_int_t *n,
              const armpl_int_t *k, const armpl_singlecomplex_t *ab,
              const armpl_int_t *ldab, float *work, ... );
```

Returns

CLANSB = (max(abs(A(i,j))), NORM = ‘M’ or ‘m’

((norm1(A), NORM = ‘1’, ‘O’ or ‘o’ ((normI(A), NORM = ‘I’ or ‘i’ ((normF(A), NORM = ‘F’, ‘f’, ‘E’ or ‘e’

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANSB as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the band matrix A is supplied. = ‘U’: Upper triangular part is supplied = ‘L’: Lower triangular part is supplied

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANSB is set to zero.

K Input parameter.

K is INTEGER

The number of super-diagonals or sub-diagonals of the band matrix A. K >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The upper or lower triangle of the symmetric band matrix A, stored in the first K+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = ‘U’, AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if UPLO = ‘L’, AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlansb*, *slansb* and *zlansb*.

4.17.89 clansp

clansp returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex symmetric matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

real function clansp(NORM, UPLO, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

float clansp_(const char *norm, const char *uplo, const armpl_int_t *n,
              const armpl_singlecomplex_t *ap, float *work, ... );
```

Returns

CLANSP = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANSP as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is supplied. = 'U': Upper triangular part of A is supplied = 'L': Lower triangular part of A is supplied

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANSP is set to zero.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlansp*, *slansp* and *zlansp*.

4.17.90 clansy

clansy returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex symmetric matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function clansy(NORM, UPLO, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

float clansy_(const char *norm, const char *uplo, const armpl_int_t *n,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              float *work, ... );
```

Returns

CLANSY = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANSY as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced. = 'U': Upper triangular part of A is referenced = 'L': Lower triangular part of A is referenced

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANSY is set to zero.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlansy*, *slansy* and *zlansy*. It also exists with a native C interface as *LAPACKE_clansy*.

4.17.91 clantb

clantb returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n by n triangular band matrix A, with (k + 1) diagonals.

Syntax

Fortran specification:

```
use armpl_library

real function clantb(NORM, UPLO, DIAG, N, K, AB, LDAB, WORK)
```

C specification:

```
#include "armpl.h"

float clantb_(const char *norm, const char *uplo, const char *diag,
              const armpl_int_t *n, const armpl_int_t *k,
              const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
              float *work, ... );
```

Returns

CLANTB = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANTB as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0. When N = 0, CLANTB is set to zero.

K Input parameter.

K is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals of the matrix A if UPLO = 'L'. K >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first k+1 rows of AB. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(k+1+i-j,j) = A(i,j) for max(1,j-k)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+k). Note that when DIAG = 'U', the elements of the array AB corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= K+1.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlantb*, *slantb* and *zlantb*.

4.17.92 clantp

`clantp` returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix A, supplied in packed form.

Syntax

Fortran specification:

```
use armpl_library

real function clantp(NORM, UPLO, DIAG, N, AP, WORK)
```

C specification:

```
#include "armpl.h"

float clantp_(const char *norm, const char *uplo, const char *diag,
              const armpl_int_t *n, const armpl_singlecomplex_t *ap,
              float *work, ... );
```

Returns

CLANTP = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

`NORM` is `CHARACTER*1`

Specifies the value to be returned in CLANTP as described above.

UPLO Input parameter.

`UPLO` is `CHARACTER*1`

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

DIAG Input parameter.

`DIAG` is `CHARACTER*1`

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

N Input parameter.

`N` is `INTEGER`

The order of the matrix A. `N` >= 0. When `N` = 0, CLANTP is set to zero.

AP Input parameter.

`AP` is `COMPLEX`

`AP` is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array `AP` as follows: if `UPLO` = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if `UPLO` = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. Note that when `DIAG` = 'U',

the elements of the array AP corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlantp*, *slantp* and *zlantp*.

4.17.93 clantr

clantr returns the value of the one norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix A.

Syntax

Fortran specification:

```
use armpl_library

real function clantr(NORM, UPLO, DIAG, M, N, A, LDA, WORK)
```

C specification:

```
#include "armpl.h"

float clantr_(const char *norm, const char *uplo, const char *diag,
              const armpl_int_t *m, const armpl_int_t *n,
              const armpl_singlecomplex_t *a, const armpl_int_t *lda,
              float *work, ... );
```

Returns

CLANTR = (max(abs(A(i,j))), NORM = 'M' or 'm'

((norm1(A), NORM = '1', 'O' or 'o' ((normI(A), NORM = 'I' or 'i' ((normF(A), NORM = 'F', 'f', 'E' or 'e'

where norm1 denotes the one norm of a matrix (maximum column sum), normI denotes the infinity norm of a matrix (maximum row sum) and normF denotes the Frobenius norm of a matrix (square root of sum of squares). Note that max(abs(A(i,j))) is not a consistent matrix norm.

Parameters

NORM Input parameter.

NORM is CHARACTER*1

Specifies the value to be returned in CLANTR as described above.

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower trapezoidal. = 'U': Upper trapezoidal = 'L': Lower trapezoidal Note that A is triangular instead of trapezoidal if M = N.

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A has unit diagonal. = 'N': Non-unit diagonal = 'U': Unit diagonal

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0, and if UPLO = 'U', M <= N. When M = 0, CLANTR is set to zero.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0, and if UPLO = 'L', N <= M. When N = 0, CLANTR is set to zero.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The trapezoidal matrix A (A is triangular if M = N). If UPLO = 'U', the leading m by n upper trapezoidal part of the array A contains the upper trapezoidal matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading m by n lower trapezoidal part of the array A contains the lower trapezoidal matrix, and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be one.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (MAX(1,LWORK)),. where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.

Related Information

For this routine in other precisions, please see *dlantr*, *slantr* and *zlantr*. It also exists with a native C interface as *LAPACKE_clantr*.

4.17.94 clapll

Given two column vectors X and Y, let

```
A = ( X Y ).
```

The subroutine first computes the QR factorization of A = Q*R, and then computes the SVD of the 2-by-2 upper triangular matrix R. The smaller singular value of R is returned in SSMIN, which is used as the measurement of the linear dependency of the vectors X and Y.

Syntax

Fortran specification:

```
use armpl_library

subroutine clapll(N, X, INCX, Y, INCY, SSMIN)
```

C specification:

```
#include "armpl.h"

void clapll_(const armpl_int_t *n, armpl_singlecomplex_t *x,
             const armpl_int_t *incx, armpl_singlecomplex_t *y,
             const armpl_int_t *incy, float *ssmin);
```

Parameters

N Input parameter.

N is INTEGER

The length of the vectors X and Y.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (1+(N-1)*INCX). On entry, X contains the N-vector X. On exit, X is overwritten.

INCX Input parameter.

INCX is INTEGER

The increment between successive elements of X. INCX > 0.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (1+(N-1)*INCY). On entry, Y contains the N-vector Y. On exit, Y is overwritten.

INCY Input parameter.

INCY is INTEGER

The increment between successive elements of Y. INCY > 0.

SSMIN Output parameter.

SSMIN is REAL

The smallest singular value of the N-by-2 matrix A = (X Y).

Related Information

For this routine in other precisions, please see *dlapll*, *slapll* and *zlapll*.

4.17.95 clapmr

clapmr rearranges the rows of the M by N matrix X as specified by the permutation K(1),K(2),...,K(M) of the integers 1,...,M. If FORWRD = .TRUE., forward permutation:

```
X(K(I),*) is moved X(I,*) for I = 1,2,...,M.
```

If FORWRD = .FALSE., backward permutation:

```
X(I,*) is moved to X(K(I),*) for I = 1,2,...,M.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine clapmr(FORWRD, M, N, X, LDX, K)
```

C specification:

```
#include "armpl.h"

void clapmr_(const armpl_int_t *forwrd, const armpl_int_t *m,
             const armpl_int_t *n, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, armpl_int_t *k);
```

Parameters

FORWRD Input parameter.

FORWRD is LOGICAL

= .TRUE., forward permutation = .FALSE., backward permutation

M Input parameter.

M is INTEGER

The number of rows of the matrix X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix X. N >= 0.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, N). On entry, the M by N matrix X. On exit, X contains the permuted matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X, LDX >= MAX(1, M).

K Input and output parameter.

K is INTEGER array, dimension (M)

On entry, K contains the permutation vector. K is used as internal workspace, but reset to its original value on output.

Related Information

For this routine in other precisions, please see *dlapmr*, *slapmr* and *zlapmr*. It also exists with a native C interface as *LAPACKE_clapmr*.

4.17.96 clapmt

clapmt rearranges the columns of the M by N matrix X as specified by the permutation K(1),K(2),...,K(N) of the integers 1,...,N. If FORWRD = .TRUE., forward permutation:

```
X(*,K(J)) is moved X(*,J) for J = 1,2,...,N.
```

If FORWRD = .FALSE., backward permutation:

```
X(*,J) is moved to X(*,K(J)) for J = 1,2,...,N.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine clapmt(FORWRD, M, N, X, LDX, K)
```

C specification:

```
#include "armpl.h"

void clapmt_(const armpl_int_t *forwrd, const armpl_int_t *m,
             const armpl_int_t *n, armpl_singlecomplex_t *x,
             const armpl_int_t *ldx, armpl_int_t *k);
```

Parameters

FORWRD Input parameter.

FORWRD is LOGICAL

= .TRUE., forward permutation = .FALSE., backward permutation

M Input parameter.

M is INTEGER

The number of rows of the matrix X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix X. N >= 0.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, N). On entry, the M by N matrix X. On exit, X contains the permuted matrix X.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the array X, LDX >= MAX(1, M).

K Input and output parameter.

K is INTEGER array, dimension (N)

On entry, K contains the permutation vector. K is used as internal workspace, but reset to its original value on output.

Related Information

For this routine in other precisions, please see *dlapmt*, *slapmt* and *zlapmt*. It also exists with a native C interface as *LAPACKE_clapmt*.

4.17.97 claqgb

`claqgb` equilibrates a general M by N band matrix A with KL subdiagonals and KU superdiagonals using the row and scaling factors in the vectors R and C.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqgb(M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void claqgb_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *kl, const armpl_int_t *ku,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             const float *r, const float *c, const float *rowcnd,
             const float *colcnd, const float *amax, char *equed, ... );
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

KL Input parameter.

KL is INTEGER

The number of subdiagonals within the band of A. KL >= 0.

KU Input parameter.

KU is INTEGER

The number of superdiagonals within the band of A. KU >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the matrix A in band storage, in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, the equilibrated matrix, in the same storage format as A. See EQUED for the form of the equilibrated matrix.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDA >= KL+KU+1.

R Input parameter.

R is REAL

R is an array, dimension (M). The row scale factors for A.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A.

ROWCND Input parameter.

ROWCND is REAL

Ratio of the smallest R(i) to the largest R(i).

COLCND Input parameter.

COLCND is REAL

Ratio of the smallest C(i) to the largest C(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C).

Related Information

For this routine in other precisions, please see *dlaqgb*, *slaqgb* and *zlaqgb*.

4.17.98 claqge

claqge equilibrates a general M by N matrix A using the row and column scaling factors in the vectors R and C.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqge(M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void claqge_(const armpl_int_t *m, const armpl_int_t *n,
             armpl_singlecomplex_t *a, const armpl_int_t *lda, const float *r,
             const float *c, const float *rowcnd, const float *colcnd,
             const float *amax, char *equed, ... );
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M by N matrix A. On exit, the equilibrated matrix. See EQUED for the form of the equilibrated matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(M,1).

R Input parameter.

R is REAL

R is an array, dimension (M). The row scale factors for A.

C Input parameter.

C is REAL

C is an array, dimension (N). The column scale factors for A.

ROWCND Input parameter.

ROWCND is REAL

Ratio of the smallest R(i) to the largest R(i).

COLCND Input parameter.

COLCND is REAL

Ratio of the smallest C(i) to the largest C(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C).

Related Information

For this routine in other precisions, please see *dlaqge*, *slaqge* and *zlaqge*.

4.17.99 claqhb

claqhb equilibrates an Hermitian band matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqhb(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void claqhb_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab, float *s,
             const float *scond, const float *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

S Output parameter.

S is REAL

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is REAL

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *zlaqhb*.

4.17.100 claqhe

claqhe equilibrates a Hermitian matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqhe(UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void claqhe_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const float *s, const float *scond,
             const float *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of

A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if EQUED = 'Y', the equilibrated matrix: diag(S) * A * diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

S Input parameter.

S is REAL

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is REAL

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *zlaqhe*.

4.17.101 claqhp

claqhp equilibrates a Hermitian matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqhp(UPLO, N, AP, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void claqhp_(const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, const float *s, const float *scond,
             const float *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the equilibrated matrix: diag(S) * A * diag(S), in the same storage format as A.

S Input parameter.

S is REAL

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is REAL

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *zlaqhp*.

4.17.102 claqp2

claqp2 computes a QR factorization with column pivoting of the block A(OFFSET+1:M,1:N). The block A(1:OFFSET,1:N) is accordingly pivoted, but not factorized.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqp2(M, N, OFFSET, A, LDA, JPVT, TAU, VN1, VN2, WORK)
```

C specification:

```
#include "armpl.h"

void claqp2_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *offset, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *jpvt,
             armpl_singlecomplex_t *tau, float *vn1, float *vn2,
             armpl_singlecomplex_t *work);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

OFFSET Input parameter.

OFFSET is INTEGER

The number of rows of the matrix A that must be pivoted but no factorized. OFFSET >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the upper triangle of block A(OFFSET+1:M,1:N) is the triangular factor obtained; the elements in block A(OFFSET+1:M,1:N) below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. Block A(1:OFFSET,1:N) has been accordingly pivoted, but no factorized.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of A*P (a leading column); if JPVT(i) = 0, the i-th column of A is a free column. On exit, if JPVT(i) = k, then the i-th column of A*P was the k-th column of A.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (min(M, N)). The scalar factors of the elementary reflectors.

VN1 Input and output parameter.

VN1 is REAL

VN1 is an array, dimension (N). The vector with the partial column norms.

VN2 Input and output parameter.

VN2 is REAL

VN2 is an array, dimension (N). The vector with the exact column norms.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

Related Information

For this routine in other precisions, please see *dlaqp2*, *slaqp2* and *zlaqp2*.

4.17.103 claqps

claqps computes a step of QR factorization with column pivoting of a complex M-by-N matrix A by using Blas-3. It tries to factorize NB columns from A starting from the row OFFSET+1, and updates all of the matrix with Blas-3 xGEMM.

In some cases, due to catastrophic cancellations, it cannot factorize NB columns. Hence, the actual number of factorized columns is returned in KB.

Block A(1:OFFSET,1:N) is accordingly pivoted, but not factorized.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqps(M, N, OFFSET, NB, KB, A, LDA, JPVT, TAU, VN1, VN2, AUXV, F,
                  LDF)
```

C specification:

```
#include "armpl.h"

void claqps_(const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *offset, const armpl_int_t *nb,
             armpl_int_t *kb, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *jpvt,
             armpl_singlecomplex_t *tau, float *vn1, float *vn2,
             armpl_singlecomplex_t *auxv, armpl_singlecomplex_t *f,
             const armpl_int_t *ldf);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0

OFFSET Input parameter.

OFFSET is INTEGER

The number of rows of A that have been factorized in previous steps.

NB Input parameter.

NB is INTEGER

The number of columns to factorize.

KB Output parameter.

KB is INTEGER

The number of columns actually factorized.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, block A(OFFSET+1:M,1:KB) is the triangular factor obtained and block A(1:OFFSET,1:N) has been accordingly pivoted, but no factorized. The rest of the matrix, block A(OFFSET+1:M,KB+1:N) has been updated.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

JPVT Input and output parameter.

JPVT is INTEGER array, dimension (N)

JPVT(I) = K <==> Column K of the full matrix A has been permuted into position I in AP.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (KB). The scalar factors of the elementary reflectors.

VN1 Input and output parameter.

VN1 is REAL

VN1 is an array, dimension (N). The vector with the partial column norms.

VN2 Input and output parameter.

VN2 is REAL

VN2 is an array, dimension (N). The vector with the exact column norms.

AUXV Input and output parameter.

AUXV is COMPLEX

AUXV is an array, dimension (NB). Auxiliar vector.

F Input and output parameter.

F is COMPLEX

F is an array, dimension (LDF, NB). Matrix $F^H = L * Y^H * A$.

LDF Input parameter.

LDF is INTEGER

The leading dimension of the array F. LDF >= max(1, N).

Related Information

For this routine in other precisions, please see *dlaqps*, *slaqps* and *zlaqps*.

4.17.104 claqr0

```
CLAQR0 computes the eigenvalues of a Hessenberg matrix H
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**H, where T is an upper triangular matrix (the
   Schur form), and Z is the unitary matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input unitary
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the unitary matrix Q:  A = Q*H*Q**H = (QZ)*H*(QZ)**H.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine claqr0(WANTT, WANTZ, N, ILO, IHI, H, LDH, W, ILOZ, IHIZ, Z, LDZ,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void claqr0_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_singlecomplex_t *h,
             const armpl_int_t *ldh, armpl_singlecomplex_t *w,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork,
             armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1, H(ILO,ILO-1) is zero. ILO and IHI are normally set by a previous call to CGEBAL, and then passed to

CGEHRD when the matrix output by CGEBAL is reduced to Hessenberg form. Otherwise, ILO and IHI should be set to 1 and N, respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is COMPLEX

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and WANTT is .TRUE., then H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If INFO = 0 and WANT is .FALSE., then the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

This subroutine may explicitly set H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

W Output parameter.

W is COMPLEX

W is an array, dimension (N). The computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored in W(ILO:IHI). If WANTT is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with W(i) = H(i,i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, IHI). If WANTZ is .FALSE., then Z is not referenced. If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the orthogonal Schur factor of H(ILO:IHI,ILO:IHI). (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if WANTZ is .TRUE. then LDZ.GE.MAX(1, IHIZ). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension LWORK. On exit, if LWORK = -1, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient, but LWORK typically as large as 6* N may be required for optimal performance. A workspace query to determine the optimal workspace size is recommended.

If LWORK = -1, then CLAQR0 does a workspace query. In this case, CLAQR0 checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: if INFO = i, CLAQR0 failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and WANT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is a unitary matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit

(final value of Z(ILO:IHI,ILOZ:IHIZ) = (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

where U is the unitary matrix in (*) (regard- less of the value of WANTT.)

If INFO .GT. 0 and WANTZ is .FALSE., then Z is not accessed.

4.17.105 claqr1

```
Given a 2-by-2 or 3-by-3 matrix H, CLAQR1 sets v to a
     scalar multiple of the first column of the product

     (*)  K = (H - s1*I)*(H - s2*I)

     scaling to avoid overflows and most underflows.

     This is useful for starting double implicit shift bulges
     in the QR algorithm.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine claqr1(N, H, LDH, S1, S2, V)
```

C specification:

```
#include "armpl.h"

void claqr1_(const armpl_int_t *n, const armpl_singlecomplex_t *h,
             const armpl_int_t *ldh, const armpl_singlecomplex_t *s1,
             armpl_singlecomplex_t *s2, armpl_singlecomplex_t *v);
```

Parameters

N Input parameter.

N is INTEGER

Order of the matrix H. N must be either 2 or 3.

H Input parameter.

H is COMPLEX

H is an array, dimension (LDH, N). The 2-by-2 or 3-by-3 matrix H in (*).

LDH Input parameter.

LDH is INTEGER

The leading dimension of H as declared in the calling procedure. LDH.GE.N

S1 Input parameter.

S1 is COMPLEX

S2 Input parameter.

S2 is COMPLEX

S1 and S2 are the shifts defining K in (*) above.

V Output parameter.

V is COMPLEX

V is an array, dimension (N). A scalar multiple of the first column of the matrix K in (*).

Related Information

For this routine in other precisions, please see *dlaqr1*, *slaqr1* and *zlaqr1*.

4.17.106 claqr2

```
CLAQR2 is identical to CLAQR3 except that it avoids
   recursion by calling CLAHQR instead of CLAQR4.

   Aggressive early deflation:

   This subroutine accepts as input an upper Hessenberg matrix
   H and performs an unitary similarity transformation
   designed to detect and deflate fully converged eigenvalues from
   a trailing principal submatrix.  On output H has been over-
   written by a new Hessenberg matrix that is a perturbation of
   an unitary similarity transformation of H.  It is to be
   hoped that the final version of H has many zero subdiagonal
   entries.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine claqr2(WANTT, WANTZ, N, KTOP, KBOT, NW, H, LDH, ILOZ, IHIZ, Z, LDZ,
                  NS, ND, SH, V, LDV, NH, T, LDT, NV, WV, LDWV, WORK, LWORK)
```

C specification:

```
#include "armpl.h"

void claqr2_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ktop,
             const armpl_int_t *kbot, const armpl_int_t *nw,
             armpl_singlecomplex_t *h, const armpl_int_t *ldh,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *ns, armpl_int_t *nd, armpl_singlecomplex_t *sh,
             armpl_singlecomplex_t *v, const armpl_int_t *ldv,
             const armpl_int_t *nh, armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, const armpl_int_t *nv,
             armpl_singlecomplex_t *wv, const armpl_int_t *ldwv,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

If .TRUE., then the Hessenberg matrix H is fully updated so that the triangular Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then only enough of H is updated to preserve the eigenvalues.

WANTZ Input parameter.

WANTZ is LOGICAL

If .TRUE., then the unitary matrix Z is updated so so that the unitary Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then Z is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix H and (if WANTZ is .TRUE.) the order of the unitary matrix Z.

KTOP Input parameter.

KTOP is INTEGER

It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

KBOT Input parameter.

KBOT is INTEGER

It is assumed without a check that either KBOT = N or H(KBOT+1, KBOT)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

NW Input parameter.

NW is INTEGER

Deflation window size. 1 .LE. NW .LE. (KBOT-KTOP+1).

H Input and output parameter.

H is COMPLEX

H is an array, dimension (LDH, N). On input the initial N-by-N section of H stores the Hessenberg matrix undergoing aggressive early deflation. On output H has been transformed by a unitary similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

LDH Input parameter.

LDH is INTEGER

Leading dimension of H just as declared in the calling subroutine. N .LE. LDH

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). IF WANTZ is .TRUE., then on output, the unitary similarity transformation mentioned above has been accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ is .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of Z just as declared in the calling subroutine. 1 .LE. LDZ.

NS Output parameter.

NS is INTEGER

The number of unconverged (ie approximate) eigenvalues returned in SR and SI that may be used as shifts by the calling subroutine.

ND Output parameter.

ND is INTEGER

The number of converged eigenvalues uncovered by this subroutine.

SH Output parameter.

SH is COMPLEX

SH is an array, dimension (KBOT). On output, approximate eigenvalues that may be used for shifts are stored in SH(KBOT-ND-NS+1) through SR(KBOT-ND). Converged eigenvalues are stored in SH(KBOT-ND+1) through SH(KBOT).

V Output parameter.

V is COMPLEX

V is an array, dimension (LDV, NW). An NW-by-NW work array.

LDV Input parameter.

LDV is INTEGER

The leading dimension of V just as declared in the calling subroutine. NW .LE. LDV

NH Input parameter.

NH is INTEGER

The number of columns of T. NH.GE.NW.

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, NW) .

LDT Input parameter.

LDT is INTEGER

The leading dimension of T just as declared in the calling subroutine. NW .LE. LDT

NV Input parameter.

NV is INTEGER

The number of rows of work array WV available for workspace. NV.GE.NW.

WV Output parameter.

WV is COMPLEX

WV is an array, dimension (LDWV, NW) .

LDWV Input parameter.

LDWV is INTEGER

The leading dimension of W just as declared in the calling subroutine. NW .LE. LDV

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK). On exit, WORK(1) is set to an estimate of the optimal value of LWORK for the given values of N, NW, KTOP and KBOT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the work array WORK. LWORK = 2*NW suffices, but greater efficiency may result from larger values of LWORK.

If LWORK = -1, then a workspace query is assumed; CLAQR2 only estimates the optimal workspace size for the given values of N, NW, KTOP and KBOT. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

Related Information

4.17.107 claqr3

```
Aggressive early deflation:

   CLAQR3 accepts as input an upper Hessenberg matrix
   H and performs an unitary similarity transformation
   designed to detect and deflate fully converged eigenvalues from
   a trailing principal submatrix.  On output H has been over-
   written by a new Hessenberg matrix that is a perturbation of
   an unitary similarity transformation of H.  It is to be
   hoped that the final version of H has many zero subdiagonal
   entries.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine claqr3(WANTT, WANTZ, N, KTOP, KBOT, NW, H, LDH, ILOZ, IHIZ, Z, LDZ,
                  NS, ND, SH, V, LDV, NH, T, LDT, NV, WV, LDWV, WORK, LWORK)
```

C specification:

```
#include "armpl.h"

void claqr3_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ktop,
             const armpl_int_t *kbot, const armpl_int_t *nw,
             armpl_singlecomplex_t *h, const armpl_int_t *ldh,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_int_t *ns, armpl_int_t *nd, armpl_singlecomplex_t *sh,
             armpl_singlecomplex_t *v, const armpl_int_t *ldv,
             const armpl_int_t *nh, armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, const armpl_int_t *nv,
             armpl_singlecomplex_t *wv, const armpl_int_t *ldwv,
             armpl_singlecomplex_t *work, const armpl_int_t *lwork);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

If .TRUE., then the Hessenberg matrix H is fully updated so that the triangular Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then only enough of H is updated to preserve the eigenvalues.

WANTZ Input parameter.

WANTZ is LOGICAL

If .TRUE., then the unitary matrix Z is updated so so that the unitary Schur factor may be computed (in cooperation with the calling subroutine). If .FALSE., then Z is not referenced.

N Input parameter.

N is INTEGER

The order of the matrix H and (if WANTZ is .TRUE.) the order of the unitary matrix Z.

KTOP Input parameter.

KTOP is INTEGER

It is assumed that either KTOP = 1 or H(KTOP,KTOP-1)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

KBOT Input parameter.

KBOT is INTEGER

It is assumed without a check that either KBOT = N or H(KBOT+1, KBOT)=0. KBOT and KTOP together determine an isolated block along the diagonal of the Hessenberg matrix.

NW Input parameter.

NW is INTEGER

Deflation window size. 1 .LE. NW .LE. (KBOT-KTOP+1).

H Input and output parameter.

H is COMPLEX

H is an array, dimension (LDH, N). On input the initial N-by-N section of H stores the Hessenberg matrix undergoing aggressive early deflation. On output H has been transformed by a unitary similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

LDH Input parameter.

LDH is INTEGER

Leading dimension of H just as declared in the calling subroutine. N .LE. LDH

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). IF WANTZ is .TRUE., then on output, the unitary similarity transformation mentioned above has been accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ is .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of Z just as declared in the calling subroutine. 1 .LE. LDZ.

NS Output parameter.

NS is INTEGER

The number of unconverged (ie approximate) eigenvalues returned in SR and SI that may be used as shifts by the calling subroutine.

ND Output parameter.

ND is INTEGER

The number of converged eigenvalues uncovered by this subroutine.

SH Output parameter.

SH is COMPLEX

SH is an array, dimension (KBOT). On output, approximate eigenvalues that may be used for shifts are stored in SH(KBOT-ND-NS+1) through SR(KBOT-ND). Converged eigenvalues are stored in SH(KBOT-ND+1) through SH(KBOT).

V Output parameter.

V is COMPLEX

V is an array, dimension (LDV, NW). An NW-by-NW work array.

LDV Input parameter.

LDV is INTEGER

The leading dimension of V just as declared in the calling subroutine. NW .LE. LDV

NH Input parameter.

NH is INTEGER

The number of columns of T. NH.GE.NW.

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, NW) .

LDT Input parameter.

LDT is INTEGER

The leading dimension of T just as declared in the calling subroutine. NW .LE. LDT

NV Input parameter.

NV is INTEGER

The number of rows of work array WV available for workspace. NV.GE.NW.

WV Output parameter.

WV is COMPLEX

WV is an array, dimension (LDWV, NW) .

LDWV Input parameter.

LDWV is INTEGER

The leading dimension of W just as declared in the calling subroutine. NW .LE. LDV

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LWORK). On exit, WORK(1) is set to an estimate of the optimal value of LWORK for the given values of N, NW, KTOP and KBOT.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the work array WORK. LWORK = 2*NW suffices, but greater efficiency may result from larger values of LWORK.

If LWORK = -1, then a workspace query is assumed; CLAQR3 only estimates the optimal workspace size for the given values of N, NW, KTOP and KBOT. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

Related Information

For this routine in other precisions, please see *dlaqr3*, *slaqr3* and *zlaqr3*.

4.17.108 claqr4

```
CLAQR4 implements one level of recursion for CLAQR0.
   It is a complete implementation of the small bulge multi-shift
   QR algorithm.  It may be called by CLAQR0 and, for large enough
   deflation window size, it may be called by CLAQR3.  This
   subroutine is identical to CLAQR0 except that it calls CLAQR2
   instead of CLAQR3.

   CLAQR4 computes the eigenvalues of a Hessenberg matrix H
```

(continues on next page)

(continued from previous page)

```
   and, optionally, the matrices T and Z from the Schur decomposition
   H = Z T Z**H, where T is an upper triangular matrix (the
   Schur form), and Z is the unitary matrix of Schur vectors.

   Optionally Z may be postmultiplied into an input unitary
   matrix Q so that this routine can give the Schur factorization
   of a matrix A which has been reduced to the Hessenberg form H
   by the unitary matrix Q:  A = Q*H*Q**H = (QZ)*H*(QZ)**H.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine claqr4(WANTT, WANTZ, N, ILO, IHI, H, LDH, W, ILOZ, IHIZ, Z, LDZ,
                  WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void claqr4_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *n, const armpl_int_t *ilo,
             const armpl_int_t *ihi, armpl_singlecomplex_t *h,
             const armpl_int_t *ldh, armpl_singlecomplex_t *w,
             armpl_int_t *iloz, armpl_int_t *ihiz, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, armpl_singlecomplex_t *work,
             const armpl_int_t *lwork, armpl_int_t *info);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

= .TRUE. : the full Schur form T is required; = .FALSE.: only eigenvalues are required.

WANTZ Input parameter.

WANTZ is LOGICAL

= .TRUE. : the matrix of Schur vectors Z is required; = .FALSE.: Schur vectors are not required.

N Input parameter.

N is INTEGER

The order of the matrix H. N .GE. 0.

ILO Input parameter.

ILO is INTEGER

IHI Input parameter.

IHI is INTEGER

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N and, if ILO.GT.1, H(ILO,ILO-1) is zero. ILO and IHI are normally set by a previous call to CGEBAL, and then passed to CGEHRD when the matrix output by CGEBAL is reduced to Hessenberg form. Otherwise, ILO and IHI should be set to 1 and N, respectively. If N.GT.0, then 1.LE.ILO.LE.IHI.LE.N. If N = 0, then ILO = 1 and IHI = 0.

H Input and output parameter.

H is COMPLEX

H is an array, dimension (LDH, N). On entry, the upper Hessenberg matrix H. On exit, if INFO = 0 and WANTT is .TRUE., then H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If INFO = 0 and WANT is .FALSE., then the contents of H are unspecified on exit. (The output value of H when INFO.GT.0 is given under the description of INFO below.)

This subroutine may explicitly set H(i,j) = 0 for i.GT.j and j = 1, 2, ... ILO-1 or j = IHI+1, IHI+2, ... N.

LDH Input parameter.

LDH is INTEGER

The leading dimension of the array H. LDH .GE. max(1, N).

W Output parameter.

W is COMPLEX

W is an array, dimension (N). The computed eigenvalues of H(ILO:IHI,ILO:IHI) are stored in W(ILO:IHI). If WANTT is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with W(i) = H(i,i).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. ILO; IHI .LE. IHIZ .LE. N.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, IHI). If WANTZ is .FALSE., then Z is not referenced. If WANTZ is .TRUE., then Z(ILO:IHI,ILOZ:IHIZ) is replaced by Z(ILO:IHI,ILOZ:IHIZ)*U where U is the orthogonal Schur factor of H(ILO:IHI,ILO:IHI). (The output value of Z when INFO.GT.0 is given under the description of INFO below.)

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. if WANTZ is .TRUE. then LDZ.GE.MAX(1, IHIZ). Otherwize, LDZ.GE.1.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension LWORK. On exit, if LWORK = -1, WORK(1) returns an estimate of the optimal value for LWORK.

LWORK Input parameter.

LWORK is INTEGER

The dimension of the array WORK. LWORK .GE. max(1, N) is sufficient, but LWORK typically as large as 6* N may be required for optimal performance. A workspace query to determine the optimal workspace size is recommended.

If LWORK = -1, then CLAQR4 does a workspace query. In this case, CLAQR4 checks the input parameters and estimates the optimal workspace size for the given values of N, ILO and IHI. The estimate is returned in WORK(1). No error message related to LWORK is issued by XERBLA. Neither H nor Z are accessed.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit .GT. 0: if INFO = i, CLAQR4 failed to compute all of the eigenvalues. Elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed. (Failures are rare.)

If INFO .GT. 0 and WANT is .FALSE., then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ILO through INFO of the final, output value of H.

If INFO .GT. 0 and WANTT is .TRUE., then on exit

(*) (initial value of H)*U = U*(final value of H)

where U is a unitary matrix. The final value of H is upper Hessenberg and triangular in rows and columns INFO+1 through IHI.

If INFO .GT. 0 and WANTZ is .TRUE., then on exit

(final value of Z(ILO:IHI,ILOZ:IHIZ) = (initial value of Z(ILO:IHI,ILOZ:IHIZ)*U

where U is the unitary matrix in (*) (regard- less of the value of WANTT.)

If INFO .GT. 0 and WANTZ is .FALSE., then Z is not accessed.

4.17.109 claqr5

```
CLAQR5 called by CLAQR0 performs a
   single small-bulge multi-shift QR sweep.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine claqr5(WANTT, WANTZ, KACC22, N, KTOP, KBOT, NSHFTS, S, H, LDH,
                  ILOZ, IHIZ, Z, LDZ, V, LDV, U, LDU, NV, WV, LDWV, NH, WH,
                  LDWH)
```

C specification:

```
#include "armpl.h"

void claqr5_(const armpl_int_t *wantt, const armpl_int_t *wantz,
             const armpl_int_t *kacc22, const armpl_int_t *n,
             const armpl_int_t *ktop, const armpl_int_t *kbot,
             const armpl_int_t *nshfts, armpl_singlecomplex_t *s,
             armpl_singlecomplex_t *h, const armpl_int_t *ldh,
             const armpl_int_t *iloz, const armpl_int_t *ihiz,
             armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *v, const armpl_int_t *ldv,
             armpl_singlecomplex_t *u, const armpl_int_t *ldu,
             const armpl_int_t *nv, armpl_singlecomplex_t *wv,
             const armpl_int_t *ldwv, const armpl_int_t *nh,
             armpl_singlecomplex_t *wh, const armpl_int_t *ldwh);
```

Parameters

WANTT Input parameter.

WANTT is LOGICAL

WANTT = .true. if the triangular Schur factor is being computed. WANTT is set to .false. otherwise.

WANTZ Input parameter.

WANTZ is LOGICAL

WANTZ = .true. if the unitary Schur factor is being computed. WANTZ is set to .false. otherwise.

KACC22 Input parameter.

KACC22 is INTEGER with value 0, 1, or 2.

Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: CLAQR5 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: CLAQR5 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: CLAQR5 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.

N Input parameter.

N is INTEGER

N is the order of the Hessenberg matrix H upon which this subroutine operates.

KTOP Input parameter.

KTOP is INTEGER

KBOT Input parameter.

KBOT is INTEGER

These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either KTOP = 1 or H(KTOP,KTOP-1) = 0 and either KBOT = N or H(KBOT+1, KBOT) = 0.

NSHFTS Input parameter.

NSHFTS is INTEGER

NSHFTS gives the number of simultaneous shifts. NSHFTS must be positive and even.

S Input and output parameter.

S is COMPLEX

S is an array, dimension (NSHFTS). S contains the shifts of origin that define the multi- shift QR sweep. On output S may be reordered.

H Input and output parameter.

H is COMPLEX

H is an array, dimension (LDH, N). On input H contains a Hessenberg matrix. On output a multi-shift QR sweep with shifts SR(J)+i*SI(J) is applied to the isolated diagonal block in rows and columns KTOP through KBOT.

LDH Input parameter.

LDH is INTEGER

LDH is the leading dimension of H just as declared in the calling procedure. LDH.GE.MAX(1, N).

ILOZ Input parameter.

ILOZ is INTEGER

IHIZ Input parameter.

IHIZ is INTEGER

Specify the rows of Z to which transformations must be applied if WANTZ is .TRUE.. 1 .LE. ILOZ .LE. IHIZ .LE. N

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, IHIZ). If WANTZ = .TRUE., then the QR Sweep unitary similarity transformation is accumulated into Z(ILOZ:IHIZ,ILOZ:IHIZ) from the right. If WANTZ = .FALSE., then Z is unreferenced.

LDZ Input parameter.

LDZ is INTEGER

LDA is the leading dimension of Z just as declared in the calling procedure. LDZ.GE.N.

V Output parameter.

V is COMPLEX

V is an array, dimension (LDV,NSHFTS/2) .

LDV Input parameter.

LDV is INTEGER

LDV is the leading dimension of V as declared in the calling procedure. LDV.GE.3.

U Output parameter.

U is COMPLEX

U is an array, dimension (LDU,3*NSHFTS-3) .

LDU Input parameter.

LDU is INTEGER

LDU is the leading dimension of U just as declared in the in the calling subroutine. LDU.GE.3*NSHFTS-3.

NH Input parameter.

NH is INTEGER

NH is the number of columns in array WH available for workspace. NH.GE.1.

WH Output parameter.

WH is COMPLEX

WH is an array, dimension (LDWH, NH) .

LDWH Input parameter.

LDWH is INTEGER

Leading dimension of WH just as declared in the calling procedure. LDWH.GE.3*NSHFTS-3.

NV Input parameter.

NV is INTEGER

NV is the number of rows in WV agailable for workspace. NV.GE.1.

WV Output parameter.

WV is COMPLEX

WV is an array, dimension (LDWV,3*NSHFTS-3) .

LDWV Input parameter.

LDWV is INTEGER

LDWV is the leading dimension of WV as declared in the in the calling subroutine. LDWV.GE.NV.

4.17.110 claqsb

claqsb equilibrates a symmetric band matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqsb(UPLO, N, KD, AB, LDAB, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void claqsb_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             const float *s, const float *scond, const float *amax,
             char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

S Input parameter.

S is REAL

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is REAL

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *dlaqsb*, *slaqsb* and *zlaqsb*.

4.17.111 claqsp

claqsp equilibrates a symmetric matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqsp(UPLO, N, AP, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void claqsp_(const char *uplo, const armpl_int_t *n,
             armpl_singlecomplex_t *ap, const float *s, const float *scond,
             const float *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input and output parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the equilibrated matrix: diag(S) * A * diag(S), in the same storage format as A.

S Input parameter.

S is REAL

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is REAL

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *dlaqsp*, *slaqsp* and *zlaqsp*.

4.17.112 claqsy

claqsy equilibrates a symmetric matrix A using the scaling factors in the vector S.

Syntax

Fortran specification:

```
use armpl_library

subroutine claqsy(UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
```

C specification:

```
#include "armpl.h"

void claqsy_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const float *s, const float *scond,
             const float *amax, char *equed, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if EQUED = 'Y', the equilibrated matrix: diag(S) * A * diag(S).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(N,1).

S Input parameter.

S is REAL

S is an array, dimension (N). The scale factors for A.

SCOND Input parameter.

SCOND is REAL

Ratio of the smallest S(i) to the largest S(i).

AMAX Input parameter.

AMAX is REAL

Absolute value of largest matrix entry.

EQUED Output parameter.

EQUED is CHARACTER*1

Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S).

Related Information

For this routine in other precisions, please see *dlaqsy*, *slaqsy* and *zlaqsy*.

4.17.113 clar1v

clar1v computes the (scaled) r-th column of the inverse of the sumbmatrix in rows B1 through BN of the tridiagonal matrix L D L^T - sigma I. When sigma is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, r corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation : (a) Stationary qd transform, L D L^T - sigma I = L(+) D(+) $L(+)^T$, (b) Progressive qd transform, L D L^T - sigma I = U(-) D(-) $U(-)^T$, (c) Computation of the diagonal elements of the inverse of

```
L D L**T - sigma I by combining the above transforms, and choosing
r as the index where the diagonal of the inverse is (one of the)
largest in magnitude.
```

(d) Computation of the (scaled) r-th column of the inverse using the

```
twisted factorization obtained by combining the top part of the
the stationary and the bottom part of the progressive transform.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine clar1v(N, B1, BN, LAMBDA, D, L, LD, LLD, PIVMIN, GAPTOL, Z, WANTNC,
                  NEGCNT, ZTZ, MINGMA, R, ISUPPZ, NRMINV, RESID, RQCORR,
                  WORK)
```

C specification:

```
#include "armpl.h"

void clar1v_(const armpl_int_t *n, const armpl_int_t *b1,
             const armpl_int_t *bn, const float *lambda, const float *d,
             const float *l, const float *ld, const float *lld,
             const float *pivmin, const float *gaptol,
             armpl_singlecomplex_t *z, const armpl_int_t *wantnc,
             armpl_int_t *negcnt, float *ztz, float *mingma, armpl_int_t *r,
             armpl_int_t *isuppz, float *nrminv, float *resid, float *rqcorr,
             float *work);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix L D L^T .

B1 Input parameter.

B1 is INTEGER

First index of the submatrix of L D L^T .

BN Input parameter.

BN is INTEGER

Last index of the submatrix of L D L^T .

LAMBDA Input parameter.

LAMBDA is REAL

The shift. In order to compute an accurate eigenvector, LAMBDA should be a good approximation to an eigenvalue of L D L^T .

L Input parameter.

L is REAL

L is an array, dimension (N-1). The (n-1) subdiagonal elements of the unit bidiagonal matrix L, in elements 1 to N-1.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D.

LD Input parameter.

LD is REAL

LD is an array, dimension (N-1). The n-1 elements L(i)*D(i).

LLD Input parameter.

LLD is REAL

LLD is an array, dimension (N-1). The n-1 elements L(i)*L(i)*D(i).

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot in the Sturm sequence.

GAPTOL Input parameter.

GAPTOL is REAL

Tolerance that indicates when eigenvector entries are negligible w.r.t. their contribution to the residual.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (N). On input, all entries of Z must be set to 0. On output, Z contains the (scaled) r-th column of the inverse. The scaling is such that Z(R) equals 1.

WANTNC Input parameter.

WANTNC is LOGICAL

Specifies whether NEGCNT has to be computed.

NEGCNT Output parameter.

NEGCNT is INTEGER

If WANTNC is .TRUE. then NEGCNT = the number of pivots < pivmin in the matrix factorization L D L^T , and NEGCNT = -1 otherwise.

ZTZ Output parameter.

ZTZ is REAL

The square of the 2-norm of Z.

MINGMA Output parameter.

MINGMA is REAL

The reciprocal of the largest (in magnitude) diagonal element of the inverse of L D L^T - sigma I.

R Input and output parameter.

R is INTEGER

The twist index for the twisted factorization used to compute Z. On input, 0 <= R <= N. If R is input as 0, R is set to the index where (L D L^T - sigma I)^{-1} is largest in magnitude. If 1 <= R <= N, R is unchanged. On output, R contains the twist index used to compute Z. Ideally, R designates the position of the maximum entry in the eigenvector.

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2)

The support of the vector in Z, i.e., the vector Z is nonzero only in elements ISUPPZ(1) through ISUPPZ(2).

NRMINV Output parameter.

NRMINV is REAL

NRMINV = 1/SQRT(ZTZ)

RESID Output parameter.

RESID is REAL

The residual of the FP vector. RESID = ABS(MINGMA)/SQRT(ZTZ)

RQCORR Output parameter.

RQCORR is REAL

The Rayleigh Quotient correction to LAMBDA. RQCORR = MINGMA*TMP

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (4*N) .

Related Information

For this routine in other precisions, please see *dlar1v*, *slar1v* and *zlar1v*.

4.17.114 clar2v

clar2v applies a vector of complex plane rotations with real cosines from both sides to a sequence of 2-by-2 complex Hermitian matrices, defined by the elements of the vectors x, y and z. For i = 1,2,...,n

```
(       x(i)  z(i) ) :=
( conjg(z(i)) y(i) )

  (  c(i) conjg(s(i)) ) (       x(i)  z(i) ) ( c(i) -conjg(s(i)) )
  ( -s(i)       c(i)  ) ( conjg(z(i)) y(i) ) ( s(i)        c(i)  )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine clar2v(N, X, Y, Z, INCX, C, S, INCC)
```

C specification:

```
#include "armpl.h"

void clar2v_(const armpl_int_t *n, armpl_singlecomplex_t *x,
             armpl_singlecomplex_t *y, armpl_singlecomplex_t *z,
             const armpl_int_t *incx, const float *c,
             const armpl_singlecomplex_t *s, const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be applied.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (1+(N-1)*INCX). The vector x; the elements of x are assumed to be real.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (1+(N-1)*INCX). The vector y; the elements of y are assumed to be real.

Z Input and output parameter.

Z is COMPLEX

Z is an array, dimension (1+(N-1)*INCX). The vector z.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X, Y and Z. INCX > 0.

C Input parameter.

C is REAL

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

S Input parameter.

S is COMPLEX

S is an array, dimension (1+(N-1)*INCC). The sines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C and S. INCC > 0.

Related Information

For this routine in other precisions, please see *dlar2v*, *slar2v* and *zlar2v*.

4.17.115 clarcm

clarcm performs a very simple matrix-matrix multiplication:

```
C := A * B,
```

where A is M by M and real; B is M by N and complex; C is M by N and complex.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarcm(M, N, A, LDA, B, LDB, C, LDC, RWORK)
```

C specification:

```
#include "armpl.h"

void clarcm_(const armpl_int_t *m, const armpl_int_t *n, const float *a,
             const armpl_int_t *lda, const armpl_singlecomplex_t *b,
             const armpl_int_t *ldb, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, float *rwork);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A and of the matrix C. M >= 0.

N Input parameter.

N is INTEGER

The number of columns and rows of the matrix B and the number of columns of the matrix C. N >= 0.

A Input parameter.

A is REAL

A is an array, dimension (LDA, M). On entry, A contains the M by M matrix A.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >=max(1, M).

B Input parameter.

B is COMPLEX

B is an array, dimension (LDB, N). On entry, B contains the M by N matrix B.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >=max(1, M).

C Output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On exit, C contains the M by N matrix C.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >=max(1, M).

RWORK Output parameter.

RWORK is REAL

RWORK is an array, dimension (2*M*N) .

Related Information

For this routine in other precisions, please see *zlarcm*. It also exists with a native C interface as *LAPACKE_clarcm*.

4.17.116 clarf

clarf applies a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**H
```

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H^H (the conjugate transpose of H), supply conjg(tau) instead tau.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarf(SIDE, M, N, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void clarf_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_singlecomplex_t *v, const armpl_int_t *incv,
            const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
            const armpl_int_t *ldc, armpl_singlecomplex_t *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

V Input parameter.

V is COMPLEX

V is an array, dimension. (1 + (M-1)*abs(INCV)) if SIDE = 'L' or (1 + (N-1)*abs(INCV)) if SIDE = 'R' The vector v in the representation of H. V is not used if TAU = 0.

INCV Input parameter.

INCV is INTEGER

The increment between elements of v. INCV <> 0.

TAU Input parameter.

TAU is COMPLEX

The value tau in the representation of H.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R'

Related Information

For this routine in other precisions, please see *dlarf*, *slarf* and *zlarf*.

4.17.117 clarfb

clarfb applies a complex block reflector H or its transpose H^H to a complex M-by-N matrix C, from either the left or the right.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarfb(SIDE, TRANS, DIRECT, STOREV, M, N, K, V, LDV, T, LDT, C,
                  LDC, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void clarfb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_singlecomplex_t *v,
             const armpl_int_t *ldv, const armpl_singlecomplex_t *t,
             const armpl_int_t *ldt, armpl_singlecomplex_t *c,
```

(continues on next page)

(continued from previous page)

```
            const armpl_int_t *ldc, armpl_singlecomplex_t *work,
            const armpl_int_t *ldwork, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^H from the Left = 'R': apply H or H^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'C': apply H^H (Conjugate transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columnwise = 'R': Rowwise

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

K Input parameter.

K is INTEGER

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

V Input parameter.

V is COMPLEX

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, M) if STOREV = 'R' and SIDE = 'L' (LDV, N) if STOREV = 'R' and SIDE = 'R' The matrix V. See Further Details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C' and SIDE = 'L', LDV >= max(1, M); if STOREV = 'C' and SIDE = 'R', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

T Input parameter.

T is COMPLEX

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by H* C or H^H * C or C*H or C*H^H .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LDWORK, K) .

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1, N); if SIDE = 'R', LDWORK >= max(1, M).

Related Information

For this routine in other precisions, please see *dlarfb*, *slarfb* and *zlarfb*. It also exists with a native C interface as *LAPACKE_clarfb*.

4.17.118 clarfg

clarfg generates a complex elementary reflector H of order n, such that

```
H**H * ( alpha ) = ( beta ),   H**H * H = I.
       (   x   )   (   0  )
```

where alpha and beta are scalars, with beta real, and x is an (n-1)-element complex vector. H is represented in the form

```
H = I - tau * ( 1 ) * ( 1 v**H ) ,
              ( v )
```

where tau is a complex scalar and v is a complex (n-1)-element vector. Note that H is not hermitian.

If the elements of x are all zero and alpha is real, then tau = 0 and H is taken to be the unit matrix.

Otherwise 1 <= real(tau) <= 2 and abs(tau-1) <= 1 .

Syntax

Fortran specification:

```
use armpl_library

subroutine clarfg(N, ALPHA, X, INCX, TAU)
```

C specification:

```
#include "armpl.h"

void clarfg_(const armpl_int_t *n, armpl_singlecomplex_t *alpha,
             armpl_singlecomplex_t *x, const armpl_int_t *incx,
             armpl_singlecomplex_t *tau);
```

Parameters

N Input parameter.

N is INTEGER

The order of the elementary reflector.

ALPHA Input and output parameter.

ALPHA is COMPLEX

On entry, the value alpha. On exit, it is overwritten with the value beta.

X Input and output parameter.

X is COMPLEX

X is an array, dimension. (1+(N-2)*abs(INCX)) On entry, the vector x. On exit, it is overwritten with the vector v.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

TAU Output parameter.

TAU is COMPLEX

The value tau.

Related Information

For this routine in other precisions, please see *dlarfg*, *slarfg* and *zlarfg*. It also exists with a native C interface as *LAPACKE_clarfg*.

4.17.119 clarfgp

clarfgp generates a complex elementary reflector H of order n, such that

```
H**H * ( alpha ) = ( beta ),   H**H * H = I.
       (   x   )   (   0  )
```

where alpha and beta are scalars, beta is real and non-negative, and x is an (n-1)-element complex vector. H is represented in the form

```
H = I - tau * ( 1 ) * ( 1 v**H ) ,
              ( v )
```

where tau is a complex scalar and v is a complex (n-1)-element vector. Note that H is not hermitian.

If the elements of x are all zero and alpha is real, then tau = 0 and H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarfgp(N, ALPHA, X, INCX, TAU)
```

C specification:

```
#include "armpl.h"

void clarfgp_(const armpl_int_t *n, armpl_singlecomplex_t *alpha,
              armpl_singlecomplex_t *x, const armpl_int_t *incx,
              armpl_singlecomplex_t *tau);
```

Parameters

N Input parameter.

N is INTEGER

The order of the elementary reflector.

ALPHA Input and output parameter.

ALPHA is COMPLEX

On entry, the value alpha. On exit, it is overwritten with the value beta.

X Input and output parameter.

X is COMPLEX

X is an array, dimension. (1+(N-2)*abs(INCX)) On entry, the vector x. On exit, it is overwritten with the vector v.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

TAU Output parameter.

TAU is COMPLEX

The value tau.

Related Information

4.17.120 clarft

clarft forms the triangular factor T of a complex block reflector H of order n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

```
H  =  I - V * T * V**H
```

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

```
H  =  I - V**H * T * V
```

Syntax

Fortran specification:

```
use armpl_library

subroutine clarft(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

C specification:

```
#include "armpl.h"

void clarft_(const char *direct, const char *storev, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_singlecomplex_t *v,
             const armpl_int_t *ldv, const armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *t, const armpl_int_t *ldt, ... );
```

Parameters

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': H = H(1) H(2) ... H(k) (Forward) = 'B': H = H(k) ... H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details): = 'C': columnwise = 'R': rowwise

N Input parameter.

N is INTEGER

The order of the block reflector H. N >= 0.

K Input parameter.

K is INTEGER

The order of the triangular factor T (= the number of elementary reflectors). K >= 1.

V Input parameter.

V is COMPLEX

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, N) if STOREV = 'R' The matrix V. See further details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, K). The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

Related Information

For this routine in other precisions, please see *dlarft*, *slarft* and *zlarft*. It also exists with a native C interface as *LAPACKE_clarft*.

4.17.121 clarfx

clarfx applies a complex elementary reflector H to a complex m by n matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**H
```

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix

This version uses inline code if H has order < 11.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarfx(SIDE, M, N, V, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void clarfx_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_singlecomplex_t *v, const armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *c, const armpl_int_t *ldc,
             armpl_singlecomplex_t *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

V Input parameter.

V is COMPLEX

V is an array, dimension (M) if SIDE = 'L'. or (N) if SIDE = 'R' The vector v in the representation of H.

TAU Input parameter.

TAU is COMPLEX

The value tau in the representation of H.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the m by n matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDA >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) if SIDE = 'L'. or (M) if SIDE = 'R' WORK is not referenced if H has order < 11.

Related Information

For this routine in other precisions, please see *dlarfx*, *slarfx* and *zlarfx*. It also exists with a native C interface as *LAPACKE_clarfx*.

4.17.122 clarfy

clarfy applies an elementary reflector, or Householder matrix, H, to an n x n Hermitian matrix C, from both the left and the right.

H is represented in the form

```
H = I - tau * v * v'
```

where tau is a scalar and v is a vector.

If tau is zero, then H is taken to be the unit matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarfy(UPLO, N, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void clarfy_(const char *uplo, const armpl_int_t *n,
             const armpl_singlecomplex_t *v, const armpl_int_t *incv,
             const armpl_singlecomplex_t *tau, armpl_singlecomplex_t *c,
             const armpl_int_t *ldc, armpl_singlecomplex_t *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix C is stored. = 'U': Upper triangle = 'L': Lower triangle

N Input parameter.

N is INTEGER

The number of rows and columns of the matrix C. N >= 0.

V Input parameter.

V is COMPLEX

V is an array, dimension. (1 + (N-1)*abs(INCV)) The vector v as described above.

INCV Input parameter.

INCV is INTEGER

The increment between successive elements of v. INCV must not be zero.

TAU Input parameter.

TAU is COMPLEX

The value tau as described above.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the matrix C. On exit, C is overwritten by H * C * H'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, N).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (N) .

Related Information

For this routine in other precisions, please see *dlarfy*, *slarfy* and *zlarfy*.

4.17.123 clargv

clargv generates a vector of complex plane rotations with real cosines, determined by elements of the complex vectors x and y. For i = 1,2,...,n

```
(        c(i)   s(i) ) ( x(i) ) = ( r(i) )
( -conjg(s(i))  c(i) ) ( y(i) ) = (   0  )

where c(i)**2 + ABS(s(i))**2 = 1
```

The following conventions are used (these are the same as in CLARTG, but differ from the BLAS1 routine CROTG):

```
 If y(i)=0, then c(i)=1 and s(i)=0.
If x(i)=0, then c(i)=0 and s(i) is chosen so that r(i) is real.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine clargv(N, X, INCX, Y, INCY, C, INCC)
```

C specification:

```
#include "armpl.h"

void clargv_(const armpl_int_t *n, armpl_singlecomplex_t *x,
             const armpl_int_t *incx, armpl_singlecomplex_t *y,
             const armpl_int_t *incy, float *c, const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be generated.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (1+(N-1)*INCX). On entry, the vector x. On exit, x(i) is overwritten by r(i), for i = 1,...,n.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (1+(N-1)*INCY). On entry, the vector y. On exit, the sines of the plane rotations.

INCY Input parameter.

INCY is INTEGER

The increment between elements of Y. INCY > 0.

C Output parameter.

C is REAL

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C. INCC > 0.

Related Information

For this routine in other precisions, please see *dlargv*, *slargv* and *zlargv*.

4.17.124 clarnv

clarnv returns a vector of n random complex numbers from a uniform or normal distribution.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarnv(IDIST, ISEED, N, X)
```

C specification:

```
#include "armpl.h"

void clarnv_(const armpl_int_t *idist, armpl_int_t *iseed,
             const armpl_int_t *n, armpl_singlecomplex_t *x);
```

Parameters

IDIST Input parameter.

IDIST is INTEGER

Specifies the distribution of the random numbers: = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc abs(z) < 1 = 5: uniformly distributed on the circle abs(z) = 1

ISEED Input and output parameter.

ISEED is INTEGER array, dimension (4)

On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and ISEED(4) must be odd. On exit, the seed is updated.

N Input parameter.

N is INTEGER

The number of random numbers to be generated.

X Output parameter.

X is COMPLEX

X is an array, dimension (N). The generated random numbers.

Related Information

For this routine in other precisions, please see *dlarnv*, *slarnv* and *zlarnv*. It also exists with a native C interface as *LAPACKE_clarnv*.

4.17.125 clarrv

clarrv computes the eigenvectors of the tridiagonal matrix T = L D L^T given L, D and APPROXIMATIONS to the eigenvalues of L D L^T . The input eigenvalues should have been computed by SLARRE.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarrv(N, VL, VU, D, L, PIVMIN, ISPLIT, M, DOL, DOU, MINRGP, RTOL1,
                  RTOL2, W, WERR, WGAP, IBLOCK, INDEXW, GERS, Z, LDZ, ISUPPZ,
                  WORK, IWORK, INFO)
```

C specification:

```
#include "armpl.h"

void clarrv_(const armpl_int_t *n, const float *vl, const float *vu, float *d,
             float *l, float *pivmin, const armpl_int_t *isplit,
             const armpl_int_t *m, const armpl_int_t *dol,
             const armpl_int_t *dou, const float *minrgp, const float *rtol1,
             const float *rtol2, float *w, float *werr, float *wgap,
             const armpl_int_t *iblock, const armpl_int_t *indexw,
             const float *gers, armpl_singlecomplex_t *z,
             const armpl_int_t *ldz, armpl_int_t *isuppz, float *work,
             armpl_int_t *iwork, armpl_int_t *info);
```

Parameters

N Input parameter.

N is INTEGER

The order of the matrix. N >= 0.

VL Input parameter.

VL is REAL

Lower bound of the interval that contains the desired eigenvalues. VL < VU. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired RANGE.

VU Input parameter.

VU is REAL

Upper bound of the interval that contains the desired eigenvalues. VL < VU. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired RANGE.

D Input and output parameter.

D is REAL

D is an array, dimension (N). On entry, the N diagonal elements of the diagonal matrix D. On exit, D may be overwritten.

L Input and output parameter.

L is REAL

L is an array, dimension (N). On entry, the (N-1) subdiagonal elements of the unit bidiagonal matrix L are in elements 1 to N-1 of L (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by SLARRE. On exit, L is overwritten.

PIVMIN Input parameter.

PIVMIN is REAL

The minimum pivot allowed in the Sturm sequence.

ISPLIT Input parameter.

ISPLIT is INTEGER array, dimension (N)

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc.

M Input parameter.

M is INTEGER

The total number of input eigenvalues. 0 <= M <= N.

DOL Input parameter.

DOL is INTEGER

DOU Input parameter.

DOU is INTEGER

If the user wants to compute only selected eigenvectors from all the eigenvalues supplied, he can specify an index range DOL:DOU. Or else the setting DOL=1, DOU=M should be applied. Note that DOL and DOU refer to the order in which the eigenvalues are stored in W. If the user wants to compute only selected eigenpairs, then the columns DOL-1 to DOU+1 of the eigenvector space Z contain the computed eigenvectors. All other columns of Z are set to zero.

MINRGP Input parameter.

MINRGP is REAL

RTOL1 Input parameter.

RTOL1 is REAL

RTOL2 Input parameter.

RTOL2 is REAL

Parameters for bisection. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|))

W Input and output parameter.

W is REAL

W is an array, dimension (N). The first M elements of W contain the APPROXIMATE eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block (The output array W from SLARRE is expected here). Furthermore, they are with respect to the shift of the corresponding root representation for their block. On exit, W holds the eigenvalues of the UNshifted matrix.

WERR Input and output parameter.

WERR is REAL

WERR is an array, dimension (N). The first M elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in W

WGAP Input and output parameter.

WGAP is REAL

WGAP is an array, dimension (N). The separation from the right neighbor eigenvalue in W.

IBLOCK Input parameter.

IBLOCK is INTEGER array, dimension (N)

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first block from the top, =2 if W(i) belongs to the second block, etc.

INDEXW Input parameter.

INDEXW is INTEGER array, dimension (N)

The indices of the eigenvalues within each block (submatrix); for example, INDEXW(i)= 10 and IBLOCK(i)=2 imply that the i-th eigenvalue W(i) is the 10-th eigenvalue in the second block.

GERS Input parameter.

GERS is REAL

GERS is an array, dimension (2*N). The N Gerschgorin intervals (the i-th Gerschgorin interval is (GERS(2*i-1), GERS(2*i)). The Gerschgorin intervals should be computed from the original UNshifted matrix.

Z Output parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, max(1, M)). If INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the input eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least max(1, M) columns are supplied in the array Z.

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1, N).

ISUPPZ Output parameter.

ISUPPZ is INTEGER array, dimension (2*max(1, M))

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The I-th eigenvector is nonzero only in elements ISUPPZ(2*I-1) through ISUPPZ(2*I).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (12*N) .

IWORK Output parameter.

IWORK is INTEGER array, dimension (7*N)

INFO Output parameter.

INFO is INTEGER

= 0: successful exit

> 0: A problem occurred in CLARRV. < 0: One of the called subroutines signaled an internal problem. Needs inspection of the corresponding parameter IINFO for further information.

=-1: Problem in SLARRB when refining a child's eigenvalues. =-2: Problem in SLARRF when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter MINRGP smaller and recompile. However, as the orthogonality of the computed vectors is proportional to 1/MINRGP, the user should be aware that he might be trading in precision when he decreases MINRGP. =-3: Problem in SLARRB when refining a single eigenvalue after the Rayleigh correction was rejected. = 5: The Rayleigh Quotient Iteration failed to converge to full accuracy in MAXITR steps.

Related Information

For this routine in other precisions, please see *dlarrv*, *slarrv* and *zlarrv*.

4.17.126 clarscl2

CLARSCL2 performs a reciprocal diagonal scaling on an vector:

```
x <-- inv(D) * x
```

where the REAL diagonal matrix D is stored as a vector.

Eventually to be replaced by BLAS_cge_diag_scale in the new BLAS standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarscl2(M, N, D, X, LDX)
```

C specification:

```
#include "armpl.h"

void clarscl2_(const armpl_int_t *m, const armpl_int_t *n, const float *d,
               armpl_singlecomplex_t *x, const armpl_int_t *ldx);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of D and X. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of X. N >= 0.

D Input parameter.

D is REAL

D is an array, length M. Diagonal matrix D, stored as a vector of length M.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (LDX, N). On entry, the vector X to be scaled by D. On exit, the scaled vector.

LDX Input parameter.

LDX is INTEGER

The leading dimension of the vector X. LDX >= M.

Related Information

For this routine in other precisions, please see *dlarscl2*, *slarscl2* and *zlarscl2*.

4.17.127 clartg

clartg generates a plane rotation so that

```
[  CS  SN  ]     [ F ]     [ R ]
[  __      ]  .  [   ]  =  [   ]   where CS**2 + |SN|**2 = 1.
[ -SN  CS  ]     [ G ]     [ 0 ]
```

This is a faster version of the BLAS1 routine CROTG, except for the following differences:

```
F and G are unchanged on return.
If G=0, then CS=1 and SN=0.
If F=0, then CS=0 and SN is chosen so that R is real.
```

Syntax

Fortran specification:

```
use armpl_library

subroutine clartg(F, G, CS, SN, R)
```

C specification:

```
#include "armpl.h"

void clartg_(const armpl_singlecomplex_t *f, const armpl_singlecomplex_t *g,
             float *cs, armpl_singlecomplex_t *sn, armpl_singlecomplex_t *r);
```

Parameters

F Input parameter.

F is COMPLEX

The first component of vector to be rotated.

G Input parameter.

G is COMPLEX

The second component of vector to be rotated.

CS Output parameter.

CS is REAL

The cosine of the rotation.

SN Output parameter.

SN is COMPLEX

The sine of the rotation.

R Output parameter.

R is COMPLEX

The nonzero component of the rotated vector.

Related Information

For this routine in other precisions, please see *dlartg*, *slartg* and *zlartg*.

4.17.128 clartv

clartv applies a vector of complex plane rotations with real cosines to elements of the complex vectors x and y. For i = 1,2,...,n

```
( x(i) ) := (         c(i)    s(i) ) ( x(i) )
( y(i) )    ( -conjg(s(i))    c(i) ) ( y(i) )
```

Syntax

Fortran specification:

```
use armpl_library

subroutine clartv(N, X, INCX, Y, INCY, C, S, INCC)
```

C specification:

```
#include "armpl.h"

void clartv_(const armpl_int_t *n, armpl_singlecomplex_t *x,
             const armpl_int_t *incx, armpl_singlecomplex_t *y,
             const armpl_int_t *incy, const float *c,
             const armpl_singlecomplex_t *s, const armpl_int_t *incc);
```

Parameters

N Input parameter.

N is INTEGER

The number of plane rotations to be applied.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (1+(N-1)*INCX). The vector x.

INCX Input parameter.

INCX is INTEGER

The increment between elements of X. INCX > 0.

Y Input and output parameter.

Y is COMPLEX

Y is an array, dimension (1+(N-1)*INCY). The vector y.

INCY Input parameter.

INCY is INTEGER

The increment between elements of Y. INCY > 0.

C Input parameter.

C is REAL

C is an array, dimension (1+(N-1)*INCC). The cosines of the plane rotations.

S Input parameter.

S is COMPLEX

S is an array, dimension (1+(N-1)*INCC). The sines of the plane rotations.

INCC Input parameter.

INCC is INTEGER

The increment between elements of C and S. INCC > 0.

Related Information

For this routine in other precisions, please see *dlartv*, *slartv* and *zlartv*.

4.17.129 clarz

clarz applies a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right. H is represented in the form

```
H = I - tau * v * v**H
```

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H^H (the conjugate transpose of H), supply conjg(tau) instead tau.

H is a product of k elementary reflectors as returned by CTZRZF.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarz(SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
```

C specification:

```
#include "armpl.h"

void clarz_(const char *side, const armpl_int_t *m, const armpl_int_t *n,
            const armpl_int_t *l, const armpl_singlecomplex_t *v,
            const armpl_int_t *incv, const armpl_singlecomplex_t *tau,
            armpl_singlecomplex_t *c, const armpl_int_t *ldc,
            armpl_singlecomplex_t *work, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': form H * C = 'R': form C * H

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

L Input parameter.

L is INTEGER

The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V Input parameter.

V is COMPLEX

V is an array, dimension (1+(L-1)*abs(INCV)). The vector v in the representation of H as returned by CTZRZF. V is not used if TAU = 0.

INCV Input parameter.

INCV is INTEGER

The increment between elements of v. INCV <> 0.

TAU Input parameter.

TAU is COMPLEX

The value tau in the representation of H.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension. (N) if SIDE = 'L' or (M) if SIDE = 'R'

Related Information

For this routine in other precisions, please see *dlarz*, *slarz* and *zlarz*.

4.17.130 clarzb

clarzb applies a complex block reflector H or its transpose H^H to a complex distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarzb(SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV, T, LDT, C,
                  LDC, WORK, LDWORK)
```

C specification:

```
#include "armpl.h"

void clarzb_(const char *side, const char *trans, const char *direct,
             const char *storev, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_int_t *k, const armpl_int_t *l,
             const armpl_singlecomplex_t *v, const armpl_int_t *ldv,
             const armpl_singlecomplex_t *t, const armpl_int_t *ldt,
             armpl_singlecomplex_t *c, const armpl_int_t *ldc,
             armpl_singlecomplex_t *work, const armpl_int_t *ldwork, ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

= 'L': apply H or H^H from the Left = 'R': apply H or H^H from the Right

TRANS Input parameter.

TRANS is CHARACTER*1

= 'N': apply H (No transpose) = 'C': apply H^H (Conjugate transpose)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet) = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV Input parameter.

STOREV is CHARACTER*1

Indicates how the vectors which define the elementary reflectors are stored: = 'C': Columnwise (not supported yet) = 'R': Rowwise

M Input parameter.

M is INTEGER

The number of rows of the matrix C.

N Input parameter.

N is INTEGER

The number of columns of the matrix C.

K Input parameter.

K is INTEGER

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L Input parameter.

L is INTEGER

The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V Input parameter.

V is COMPLEX

V is an array, dimension (LDV,NV).. If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= L; if STOREV = 'R', LDV >= K.

T Input parameter.

T is COMPLEX

T is an array, dimension (LDT, K). The triangular K-by-K matrix T in the representation of the block reflector.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

C Input and output parameter.

C is COMPLEX

C is an array, dimension (LDC, N). On entry, the M-by-N matrix C. On exit, C is overwritten by H* C or H^H * C or C*H or C*H^H .

LDC Input parameter.

LDC is INTEGER

The leading dimension of the array C. LDC >= max(1, M).

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (LDWORK, K) .

LDWORK Input parameter.

LDWORK is INTEGER

The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1, N); if SIDE = 'R', LDWORK >= max(1, M).

Related Information

For this routine in other precisions, please see *dlarzb*, *slarzb* and *zlarzb*.

4.17.131 clarzt

`clarzt` forms the triangular factor T of a complex block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = '`C`', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

```
H  =  I - V * T * V**H
```

If STOREV = '`R`', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

```
H  =  I - V**H * T * V
```

Currently, only STOREV = '`R`' and DIRECT = 'B' are supported.

Syntax

Fortran specification:

```
use armpl_library

subroutine clarzt(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

C specification:

```
#include "armpl.h"

void clarzt_(const char *direct, const char *storev, const armpl_int_t *n,
             const armpl_int_t *k, armpl_singlecomplex_t *v,
             const armpl_int_t *ldv, const armpl_singlecomplex_t *tau,
             armpl_singlecomplex_t *t, const armpl_int_t *ldt, ... );
```

Parameters

`DIRECT` Input parameter.

`DIRECT` is `CHARACTER*1`

Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet) = 'B': H = H(k) . . . H(2) H(1) (Backward)

`STOREV` Input parameter.

`STOREV` is `CHARACTER*1`

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details): = '`C`': columnwise (not supported yet) = '`R`': rowwise

`N` Input parameter.

`N` is `INTEGER`

The order of the block reflector H. `N` >= 0.

`K` Input parameter.

`K` is `INTEGER`

The order of the triangular factor `T` (= the number of elementary reflectors). `K` >= 1.

V Input and output parameter.

V is COMPLEX

V is an array, dimension. (LDV, K) if STOREV = 'C' (LDV, N) if STOREV = 'R' The matrix V. See further details.

LDV Input parameter.

LDV is INTEGER

The leading dimension of the array V. If STOREV = 'C', LDV >= max(1, N); if STOREV = 'R', LDV >= K.

TAU Input parameter.

TAU is COMPLEX

TAU is an array, dimension (K). TAU(i) must contain the scalar factor of the elementary reflector H(i).

T Output parameter.

T is COMPLEX

T is an array, dimension (LDT, K). The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= K.

Related Information

For this routine in other precisions, please see *dlarzt*, *slarzt* and *zlarzt*.

4.17.132 clascl

clascl multiplies the M by N complex matrix A by the real scalar CTO/CFROM. This is done without over/underflow as long as the final result CTO*A(I,J)/CFROM does not over/underflow. TYPE specifies that A may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Syntax

Fortran specification:

```
use armpl_library

subroutine clascl(TYPE, KL, KU, CFROM, CTO, M, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void clascl_(const char *type, const armpl_int_t *kl, const armpl_int_t *ku,
             const float *cfrom, const float *cto, const armpl_int_t *m,
             const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

TYPE Input parameter.

TYPE is CHARACTER*1

TYPE indices the storage type of the input matrix. = 'G': A is a full matrix. = 'L': A is a lower triangular matrix. = 'U': A is an upper triangular matrix. = 'H': A is an upper Hessenberg matrix. = 'B': A is a symmetric band matrix with lower bandwidth KL and upper bandwidth KU and with the only the lower half stored. = 'Q': A is a symmetric band matrix with lower bandwidth KL and upper bandwidth KU and with the only the upper half stored. = 'Z': A is a band matrix with lower bandwidth KL and upper bandwidth KU. See CGBTRF for storage details.

KL Input parameter.

KL is INTEGER

The lower bandwidth of A. Referenced only if TYPE = 'B', 'Q' or 'Z'.

KU Input parameter.

KU is INTEGER

The upper bandwidth of A. Referenced only if TYPE = 'B', 'Q' or 'Z'.

CFROM Input parameter.

CFROM is REAL

CTO Input parameter.

CTO is REAL

The matrix A is multiplied by CTO/CFROM. A(I,J) is computed without over/underflow if the final result CTO*A(I,J)/CFROM can be represented without over/underflow. CFROM must be nonzero.

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The matrix to be multiplied by CTO/CFROM. See TYPE for the storage type.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. If TYPE = 'G', 'L', 'U', 'H', LDA >= max(1, M); TYPE = 'B', LDA >= KL+1; TYPE = 'Q', LDA >= KU+1; TYPE = 'Z', LDA >= 2*KL+KU+1.

INFO Output parameter.

INFO is INTEGER

0 - successful exit <0 - if INFO = -i, the i-th argument had an illegal value.

Related Information

For this routine in other precisions, please see *dlascl*, *slascl* and *zlascl*. It also exists with a native C interface as *LAPACKE_clascl*.

4.17.133 clascl2

`clascl2` performs a diagonal scaling on a vector:

```
x <-- D * x
```

where the diagonal REAL matrix D is stored as a vector.

Eventually to be replaced by BLAS_cge_diag_scale in the new BLAS standard.

Syntax

Fortran specification:

```
use armpl_library

subroutine clascl2(M, N, D, X, LDX)
```

C specification:

```
#include "armpl.h"

void clascl2_(const armpl_int_t *m, const armpl_int_t *n, const float *d,
              armpl_singlecomplex_t *x, const armpl_int_t *ldx);
```

Parameters

M Input parameter.

`M` is `INTEGER`

The number of rows of `D` and `X`. `M` >= 0.

N Input parameter.

`N` is `INTEGER`

The number of columns of `X`. `N` >= 0.

D Input parameter.

`D` is `REAL`

`D` is an array, length `M`. Diagonal matrix `D`, stored as a vector of length `M`.

X Input and output parameter.

`X` is `COMPLEX`

`X` is an array, dimension (`LDX`, `N`). On entry, the vector `X` to be scaled by `D`. On exit, the scaled vector.

LDX Input parameter.

`LDX` is `INTEGER`

The leading dimension of the vector `X`. `LDX` >= `M`.

Related Information

For this routine in other precisions, please see *dlascl2*, *slascl2* and *zlascl2*.

4.17.134 claset

`claset` initializes a 2-D array A to BETA on the diagonal and ALPHA on the offdiagonals.

Syntax

Fortran specification:

```
use armpl_library

subroutine claset(UPLO, M, N, ALPHA, BETA, A, LDA)
```

C specification:

```
#include "armpl.h"

void claset_(const char *uplo, const armpl_int_t *m, const armpl_int_t *n,
             const armpl_singlecomplex_t *alpha,
             const armpl_singlecomplex_t *beta, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies the part of the matrix A to be set. = 'U': Upper triangular part is set. The lower triangle is unchanged. = 'L': Lower triangular part is set. The upper triangle is unchanged. Otherwise: All of the matrix A is set.

M Input parameter.

M is INTEGER

On entry, M specifies the number of rows of A.

N Input parameter.

N is INTEGER

On entry, N specifies the number of columns of A.

ALPHA Input parameter.

ALPHA is COMPLEX

All the offdiagonal array elements are set to ALPHA.

BETA Input parameter.

BETA is COMPLEX

All the diagonal array elements are set to BETA.

A Output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the m by n matrix A. On exit, A(i,j) = ALPHA, 1 <= i <= m, 1 <= j <= n, i.ne.j; A(i,i) = BETA , 1 <= i <= min(m,n)

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

For this routine in other precisions, please see *dlaset*, *slaset* and *zlaset*. It also exists with a native C interface as *LAPACKE_claset*.

4.17.135 clasr

clasr applies a sequence of real plane rotations to a complex matrix A, from either the left or the right.

When SIDE = 'L', the transformation takes the form

```
A := P*A
```

and when SIDE = 'R', the transformation takes the form

```
A := A*P**T
```

where P is an orthogonal matrix consisting of a sequence of z plane rotations, with z = M when SIDE = 'L' and z = N when SIDE = 'R', and P^T is the transpose of P.

When DIRECT = 'F' (Forward sequence), then

```
P = P(z-1) * ... * P(2) * P(1)
```

and when DIRECT = 'B' (Backward sequence), then

```
P = P(1) * P(2) * ... * P(z-1)
```

where P(k) is a plane rotation matrix defined by the 2-by-2 rotation

```
R(k) = (  c(k)  s(k) )
     = ( -s(k)  c(k) ).
```

When PIVOT = 'V' (Variable pivot), the rotation is performed for the plane (k,k+1), i.e., P(k) has the form

```
P(k) = (  1                                          )
       (       ...                                   )
       (               1                             )
       (                    c(k)  s(k)               )
       (                   -s(k)  c(k)               )
       (                             1               )
       (                                  ...        )
       (                                         1   )
```

where R(k) appears as a rank-2 modification to the identity matrix in rows and columns k and k+1.

When PIVOT = 'T' (Top pivot), the rotation is performed for the plane (1,k+1), so P(k) has the form

```
P(k) = (  c(k)                    s(k)               )
       (         1                                   )
       (              ...                            )
       (                      1                      )
       ( -s(k)                c(k)                   )
       (                             1               )
       (                                  ...        )
       (                                         1   )
```

where R(k) appears in rows and columns 1 and k+1.

Similarly, when PIVOT = 'B' (Bottom pivot), the rotation is performed for the plane (k,z), giving P(k) the form

```
P(k) = ( 1                                          )
       (      ...                                   )
       (              1                             )
       (                    c(k)           s(k)     )
       (                           1                )
       (                                  ...       )
       (                                        1   )
       (                   -s(k)          c(k)     )
```

where R(k) appears in rows and columns k and z. The rotations are performed without ever forming P(k) explicitly.

Syntax

Fortran specification:

```
use armpl_library

subroutine clasr(SIDE, PIVOT, DIRECT, M, N, C, S, A, LDA)
```

C specification:

```
#include "armpl.h"

void clasr_(const char *side, const char *pivot, const char *direct,
            const armpl_int_t *m, const armpl_int_t *n, const float *c,
            const float *s, armpl_singlecomplex_t *a, const armpl_int_t *lda,
            ... );
```

Parameters

SIDE Input parameter.

SIDE is CHARACTER*1

Specifies whether the plane rotation matrix P is applied to A on the left or the right. = 'L': Left, compute A := P*A = 'R': Right, compute A:= A*P^T

PIVOT Input parameter.

PIVOT is CHARACTER*1

Specifies the plane for which P(k) is a plane rotation matrix. = 'V': Variable pivot, the plane (k,k+1) = 'T': Top pivot, the plane (1,k+1) = 'B': Bottom pivot, the plane (k,z)

DIRECT Input parameter.

DIRECT is CHARACTER*1

Specifies whether P is a forward or backward sequence of plane rotations. = 'F': Forward, P = P(z-1)*...*P(2)*P(1) = 'B': Backward, P = P(1)*P(2)*...*P(z-1)

M Input parameter.

M is INTEGER

The number of rows of the matrix A. If m <= 1, an immediate return is effected.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. If n <= 1, an immediate return is effected.

C Input parameter.

C is REAL

C is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' The cosines c(k) of the plane rotations.

S Input parameter.

S is REAL

S is an array, dimension. (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' The sines s(k) of the plane rotations. The 2-by-2 plane rotation part of the matrix P(k), R(k), has the form R(k) = (c(k) s(k)) (-s(k) c(k)).

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The M-by-N matrix A. On exit, A is overwritten by P* A if SIDE = 'R' or by A*P^T if SIDE = 'L'.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

Related Information

For this routine in other precisions, please see *dlasr*, *slasr* and *zlasr*.

4.17.136 classq

classq returns the values scl and ssq such that

```
( scl**2 )*ssq = x( 1 )**2 +...+ x( n )**2 + ( scale**2 )*sumsq,
```

where x(i) = abs(X(1 + (i - 1)*INCX)). The value of sumsq is assumed to be at least unity and the value of ssq will then satisfy

```
1.0 .le. ssq .le. ( sumsq + 2*n ).
```

scale is assumed to be non-negative and scl returns the value

```
scl = max( scale, abs( real( x( i ) ) ), abs( aimag( x( i ) ) ) ),
      i
```

scale and sumsq must be supplied in SCALE and SUMSQ respectively. SCALE and SUMSQ are overwritten by scl and ssq respectively.

The routine makes only one pass through the vector X.

Syntax

Fortran specification:

```
use armpl_library

subroutine classq(N, X, INCX, SCALE, SUMSQ)
```

C specification:

```
#include "armpl.h"

void classq_(const armpl_int_t *n, const armpl_singlecomplex_t *x,
             const armpl_int_t *incx, float *scale, float *sumsq);
```

Parameters

N Input parameter.

N is INTEGER

The number of elements to be used from the vector X.

X Input parameter.

X is COMPLEX

X is an array, dimension (N). The vector x as described above. x(i) = X(1 + (i - 1)* INCX), 1 <= i <= n.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of the vector X. INCX > 0.

SCALE Input and output parameter.

SCALE is REAL

On entry, the value scale in the equation above. On exit, SCALE is overwritten with the value scl .

SUMSQ Input and output parameter.

SUMSQ is REAL

On entry, the value sumsq in the equation above. On exit, SUMSQ is overwritten with the value ssq .

Related Information

For this routine in other precisions, please see *dlassq*, *slassq* and *zlassq*. It also exists with a native C interface as *LAPACKE_classq*.

4.17.137 claswlq

claswlq computes a blocked Short-Wide LQ factorization of a M-by-N matrix A, where N >= M: A = L * Q

Syntax

Fortran specification:

```
use armpl_library

subroutine claswlq(M, N, MB, NB, A, LDA, T, LDT, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void claswlq_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *mb, const armpl_int_t *nb,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *t, const armpl_int_t *ldt,
```

(continues on next page)

(continued from previous page)

```
                armpl_singlecomplex_t *work, const armpl_int_t *lwork,
                armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= M >= 0.

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. M >= MB >= 1

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. NB > M.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the N-by-N lower triangular matrix L; the elements above the diagonal represent Q by the rows of blocked V (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array,. dimension (LDT, N * Number_of_row_blocks) where Number_of_row_blocks = CEIL((N-M)/(NB-M)) The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details below.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= MB.

WORK Output parameter.

(workspace) COMPLEX

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

The dimension of the array WORK. LWORK >= MB*M.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dlaswlq*, *slaswlq* and *zlaswlq*.

4.17.138 claswp

claswp performs a series of row interchanges on the matrix A. One row interchange is initiated for each of rows K1 through K2 of A.

Syntax

Fortran specification:

```
use armpl_library

subroutine claswp(N, A, LDA, K1, K2, IPIV, INCX)
```

C specification:

```
#include "armpl.h"

void claswp_(const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, const armpl_int_t *k1,
             const armpl_int_t *k2, const armpl_int_t *ipiv,
             const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of columns of the matrix A.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the matrix of column dimension N to which the row interchanges will be applied. On exit, the permuted matrix.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A.

K1 Input parameter.

K1 is INTEGER

The first element of IPIV for which a row interchange will be done.

K2 Input parameter.

K2 is INTEGER

(K2-K1+1) is the number of elements of IPIV for which a row interchange will be done.

IPIV Input parameter.

IPIV is INTEGER array, dimension (K1+(K2-K1)*abs(INCX))

The vector of pivot indices. Only the elements in positions K1 through K1+(K2-K1)*abs(INCX) of IPIV are accessed. IPIV(K1+(K-K1)*abs(INCX)) = L implies rows K and L are to be interchanged.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of IPIV. If INCX is negative, the pivots are applied in reverse order.

Related Information

For this routine in other precisions, please see *dlaswp*, *slaswp* and *zlaswp*. It also exists with a native C interface as *LAPACKE_claswp*.

4.17.139 clasyf

clasyf computes a partial factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L'

```
( L21  I ) ( 0   A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB. Note that U^T denotes the transpose of U.

clasyf is an auxiliary routine called by CSYTRF. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine clasyf(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void clasyf_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             armpl_int_t *kb, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv,
             armpl_singlecomplex_t *w, const armpl_int_t *ldw,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is COMPLEX

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

4.17.140 clasyf_aa

DLATRF_AA factorizes a panel of a complex symmetric matrix A using the Aasen's algorithm. The panel consists of a set of NB rows of A when UPLO is U, or a set of NB columns when UPLO is L.

In order to factorize the panel, the Aasen's algorithm requires the last row, or column, of the previous panel. The first row, or column, of A is set to be the first row, or column, of an identity matrix, which is used to factorize the first panel.

The resulting J-th row of U, or J-th column of L, is stored in the (J-1)-th row, or column, of A (without the unit diagonals), while the diagonal and subdiagonal of A are overwritten by those of T.

Syntax

Fortran specification:

```
use armpl_library

subroutine clasyf_aa(UPLO, J1, M, NB, A, LDA, IPIV, H, LDH, WORK)
```

C specification:

```
#include "armpl.h"

void clasyf_aa_(const char *uplo, const armpl_int_t *j1, const armpl_int_t *m,
                const armpl_int_t *nb, armpl_singlecomplex_t *a,
                const armpl_int_t *lda, armpl_int_t *ipiv,
                armpl_singlecomplex_t *h, const armpl_int_t *ldh,
                armpl_singlecomplex_t *work, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

= 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored.

J1 Input parameter.

J1 is INTEGER

The location of the first row, or column, of the panel within the submatrix of A, passed to this routine, e.g., when called by CSYTRF_AA, for the first panel, J1 is 1, while for the remaining panels, J1 is 2.

M Input parameter.

M is INTEGER

The dimension of the submatrix. M >= 0.

NB Input parameter.

NB is INTEGER

The dimension of the panel to be facotorized.

A Input and output parameter.

A is REAL

A is an array, dimension (LDA, M) for. the first panel, while dimension (LDA,M+1) for the remaining panels.

On entry, A contains the last row, or column, of the previous panel, and the trailing submatrix of A to be factorized, except for the first panel, only the panel is passed.

On exit, the leading panel is factorized.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

IPIV Output parameter.

IPIV is INTEGER array, dimension (M)

Details of the row and column interchanges, the row and column k were interchanged with the row and column IPIV(k).

H Input and output parameter.

H is REAL workspace, dimension (LDH, NB).

LDH Input parameter.

LDH is INTEGER

The leading dimension of the workspace H. LDH >= max(1, M).

WORK Output parameter.

WORK is REAL workspace, dimension (M).

4.17.141 clasyf_rook

CLASYF_ROOK computes a partial factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The partial factorization has the form:

A = (I U12) (A11 0) (I 0) if UPLO = 'U', or:

```
( 0  U22 ) (  0   D  ) ( U12**T U22**T )
```

A = (L11 0) (D 0) ($L11^T$ $L21^T$) if UPLO = 'L'

```
( L21  I ) (  0  A22 ) (  0       I    )
```

where the order of D is at most NB. The actual order is returned in the argument KB, and is either NB or NB-1, or N if N <= NB.

CLASYF_ROOK is an auxiliary routine called by CSYTRF_ROOK. It uses blocked code (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Syntax

Fortran specification:

```
use armpl_library

subroutine clasyf_rook(UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
```

C specification:

```
#include "armpl.h"

void clasyf_rook_(const char *uplo, const armpl_int_t *n,
                  const armpl_int_t *nb, armpl_int_t *kb,
                  armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_singlecomplex_t *w,
                  const armpl_int_t *ldw, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

NB Input parameter.

NB is INTEGER

The maximum number of columns of the matrix A that should be factored. NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB Output parameter.

KB is INTEGER

The number of columns of A that were actually factored. KB is either NB-1 or NB, or N if N <= NB.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, A contains details of the partial factorization.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': Only the last KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': Only the first KB elements of IPIV are set.

If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k+1 and -IPIV(k+1) were inerchaged, D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W Output parameter.

W is COMPLEX

W is an array, dimension (LDW, NB) .

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

Related Information

For this routine in other precisions, please see *dlasyf_rook*, *slasyf_rook* and *zlasyf_rook*.

4.17.142 clatbs

clatbs solves one of the triangular systems

```
A * x = s*b,  A**T * x = s*b,  or  A**H * x = s*b,
```

with scaling to prevent overflow, where A is an upper or lower triangular band matrix. Here A^T denotes the transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine CTBSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine clatbs(UPLO, TRANS, DIAG, NORMIN, N, KD, AB, LDAB, X, SCALE, CNORM,
                  INFO)
```

C specification:

```
#include "armpl.h"

void clatbs_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n, const armpl_int_t *kd,
             const armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             armpl_singlecomplex_t *x, float *scale, float *cnorm,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^H * x = s*b (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of subdiagonals or superdiagonals in the triangular matrix A. KD >= 0.

AB Input parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). The upper or lower triangular band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is REAL

The scaling factor s for the triangular system A * x = s*b, A^T * x = s*b, or A^H * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is REAL

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dlatbs*, *slatbs* and *zlatbs*.

4.17.143 clatdf

clatdf computes the contribution to the reciprocal Dif-estimate by solving for x in Z * x = b, where b is chosen such that the norm of x is as large as possible. It is assumed that LU decomposition of Z has been computed by CGETC2. On entry RHS = f holds the contribution from earlier solved sub-systems, and on return RHS = x.

The factorization of Z returned by CGETC2 has the form Z = P * L * U * Q, where P and Q are permutation matrices. L is lower triangular with unit diagonal elements and U is upper triangular.

Syntax

Fortran specification:

```
use armpl_library

subroutine clatdf(IJOB, N, Z, LDZ, RHS, RDSUM, RDSCAL, IPIV, JPIV)
```

C specification:

```
#include "armpl.h"

void clatdf_(const armpl_int_t *ijob, const armpl_int_t *n,
             const armpl_singlecomplex_t *z, const armpl_int_t *ldz,
             armpl_singlecomplex_t *rhs, float *rdsum, float *rdscal,
             const armpl_int_t *ipiv, const armpl_int_t *jpiv);
```

Parameters

IJOB Input parameter.

IJOB is INTEGER

IJOB = 2: First compute an approximative null-vector e of Z using CGECON, e is normalized and solve for Zx = +-e - f with the sign giving the greater value of 2-norm(x). About 5 times as expensive as Default. IJOB .ne. 2: Local look ahead strategy where all entries of the r.h.s. b is chosen as either +1 or -1. Default.

N Input parameter.

N is INTEGER

The number of columns of the matrix Z.

Z Input parameter.

Z is COMPLEX

Z is an array, dimension (LDZ, N). On entry, the LU part of the factorization of the n-by-n matrix Z computed by CGETC2: Z = P * L * U * Q

LDZ Input parameter.

LDZ is INTEGER

The leading dimension of the array Z. LDA >= max(1, N).

RHS Input and output parameter.

RHS is COMPLEX

RHS is an array, dimension (N).. On entry, RHS contains contributions from other subsystems. On exit, RHS contains the solution of the subsystem with entries according to the value of IJOB (see above).

RDSUM Input and output parameter.

RDSUM is REAL

On entry, the sum of squares of computed contributions to the Dif-estimate under computation by CTGSYL, where the scaling factor RDSCAL (see below) has been factored out. On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If TRANS = 'T' RDSUM is not touched. NOTE: RDSUM only makes sense when CTGSY2 is called by CTGSYL.

RDSCAL Input and output parameter.

RDSCAL is REAL

On entry, scaling factor used to prevent overflow in RDSUM. On exit, RDSCAL is updated w.r.t. the current contributions in RDSUM. If TRANS = 'T', RDSCAL is not touched. NOTE: RDSCAL only makes sense when CTGSY2 is called by CTGSYL.

IPIV Input parameter.

IPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= i <= N, row i of the matrix has been interchanged with row IPIV(i).

JPIV Input parameter.

JPIV is INTEGER array, dimension (N).

The pivot indices; for 1 <= j <= N, column j of the matrix has been interchanged with column JPIV(j).

Related Information

For this routine in other precisions, please see *dlatdf*, *slatdf* and *zlatdf*.

4.17.144 clatps

clatps solves one of the triangular systems

```
A * x = s*b,  A**T * x = s*b,  or  A**H * x = s*b,
```

with scaling to prevent overflow, where A is an upper or lower triangular matrix stored in packed form. Here A^T denotes the transpose of A, A^H denotes the conjugate transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine CTPSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine clatps(UPLO, TRANS, DIAG, NORMIN, N, AP, X, SCALE, CNORM, INFO)
```

C specification:

```
#include "armpl.h"

void clatps_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n,
             const armpl_singlecomplex_t *ap, armpl_singlecomplex_t *x,
             float *scale, float *cnorm, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^H * x = s*b (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

AP Input parameter.

AP is COMPLEX

AP is an array, dimension (N*(N+1)/2). The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

X Input and output parameter.

X is COMPLEX

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is REAL

The scaling factor s for the triangular system A * x = s*b, A^T * x = s*b, or A^H * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is REAL

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dlatps*, *slatps* and *zlatps*.

4.17.145 clatrd

clatrd reduces NB rows and columns of a complex Hermitian matrix A to Hermitian tridiagonal form by a unitary similarity transformation Q^H * A * Q, and returns the matrices V and W which are needed to apply the transformation to the unreduced part of A.

If UPLO = 'U', clatrd reduces the last NB rows and columns of a matrix, of which the upper triangle is supplied; if UPLO = 'L', clatrd reduces the first NB rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by CHETRD.

Syntax

Fortran specification:

```
use armpl_library

subroutine clatrd(UPLO, N, NB, A, LDA, E, TAU, W, LDW)
```

C specification:

```
#include "armpl.h"

void clatrd_(const char *uplo, const armpl_int_t *n, const armpl_int_t *nb,
             armpl_singlecomplex_t *a, const armpl_int_t *lda, float *e,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *w,
             const armpl_int_t *ldw, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A.

NB Input parameter.

NB is INTEGER

The number of rows and columns to be reduced.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit: if UPLO = 'U', the last NB columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of A; the elements above the diagonal with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the first NB columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of A; the elements below the diagonal with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

E Output parameter.

E is REAL

E is an array, dimension (N-1). If UPLO = 'U', E(n-nb:n-1) contains the superdiagonal elements of the last NB columns of the reduced matrix; if UPLO = 'L', E(1:nb) contains the subdiagonal elements of the first NB columns of the reduced matrix.

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (N-1). The scalar factors of the elementary reflectors, stored in TAU(n-nb:n-1) if UPLO = 'U', and in TAU(1:nb) if UPLO = 'L'. See Further Details.

W Output parameter.

W is COMPLEX

W is an array, dimension (LDW, NB). The n-by-nb matrix W required to update the unreduced part of A.

LDW Input parameter.

LDW is INTEGER

The leading dimension of the array W. LDW >= max(1, N).

Related Information

For this routine in other precisions, please see *dlatrd*, *slatrd* and *zlatrd*.

4.17.146 clatrs

clatrs solves one of the triangular systems

```
A * x = s*b,  A**T * x = s*b,  or  A**H * x = s*b,
```

with scaling to prevent overflow. Here A is an upper or lower triangular matrix, A^T denotes the transpose of A, A^H denotes the conjugate transpose of A, x and b are n-element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine CTRSV is called. If the matrix A is singular (A(j,j) = 0 for some j), then s is set to 0 and a non-trivial solution to A*x = 0 is returned.

Syntax

Fortran specification:

```
use armpl_library

subroutine clatrs(UPLO, TRANS, DIAG, NORMIN, N, A, LDA, X, SCALE, CNORM,
                  INFO)
```

C specification:

```
#include "armpl.h"

void clatrs_(const char *uplo, const char *trans, const char *diag,
             const char *normin, const armpl_int_t *n,
             const armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *x, float *scale, float *cnorm,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular

TRANS Input parameter.

TRANS is CHARACTER*1

Specifies the operation applied to A. = 'N': Solve A * x = s*b (No transpose) = 'T': Solve A^T * x = s*b (Transpose) = 'C': Solve A^H * x = s*b (Conjugate transpose)

DIAG Input parameter.

DIAG is CHARACTER*1

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular

NORMIN Input parameter.

NORMIN is CHARACTER*1

Specifies whether CNORM has been set or not. = 'Y': CNORM contains the column norms on entry = 'N': CNORM is not set on entry. On exit, the norms will be computed and stored in CNORM.

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max (1, N).

X Input and output parameter.

X is COMPLEX

X is an array, dimension (N). On entry, the right hand side b of the triangular system. On exit, X is overwritten by the solution vector x.

SCALE Output parameter.

SCALE is REAL

The scaling factor s for the triangular system A * x = s*b, A^T * x = s*b, or A^H * x = s*b. If SCALE = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to A*x = 0.

CNORM Input and output parameter.

CNORM is REAL

CNORM is an array, dimension (N). If NORMIN = 'Y', CNORM is an input argument and CNORM(j) contains the norm of the off-diagonal part of the j-th column of A. If TRANS = 'N', CNORM(j) must be greater than or equal to the infinity-norm, and if TRANS = 'T' or 'C', CNORM(j) must be greater than or equal to the 1-norm.

If NORMIN = 'N', CNORM is an output argument and CNORM(j) returns the 1-norm of the offdiagonal part of the j-th column of A.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

4.17.147 clatrz

clatrz factors the M-by-(M+L) complex upper trapezoidal matrix [A1 A2] = [A(1:M,1:M) A(1:M,N-L+1:N)] as (R 0) * Z by means of unitary transformations, where Z is an (M+L)-by-(M+L) unitary matrix and, R and A1 are M-by-M upper triangular matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine clatrz(M, N, L, A, LDA, TAU, WORK)
```

C specification:

```
#include "armpl.h"

void clatrz_(const armpl_int_t *m, const armpl_int_t *n, const armpl_int_t *l,
             armpl_singlecomplex_t *a, const armpl_int_t *lda,
             armpl_singlecomplex_t *tau, armpl_singlecomplex_t *work);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. N >= 0.

L Input parameter.

L is INTEGER

The number of columns of the matrix A containing the meaningful part of the Householder vectors. N-M >= L >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements N-L+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

TAU Output parameter.

TAU is COMPLEX

TAU is an array, dimension (M). The scalar factors of the elementary reflectors.

WORK Output parameter.

WORK is COMPLEX

WORK is an array, dimension (M) .

Related Information

For this routine in other precisions, please see *dlatrz*, *slatrz* and *zlatrz*.

4.17.148 clatsqr

SLATSQR computes a blocked Tall-Skinny QR factorization of an M-by-N matrix A, where M >= N: A = Q * R .

Syntax

Fortran specification:

```
use armpl_library

subroutine clatsqr(M, N, MB, NB, A, LDA, T, LDT, WORK, LWORK, INFO)
```

C specification:

```
#include "armpl.h"

void clatsqr_(const armpl_int_t *m, const armpl_int_t *n,
              const armpl_int_t *mb, const armpl_int_t *nb,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              armpl_singlecomplex_t *t, const armpl_int_t *ldt,
              armpl_singlecomplex_t *work, const armpl_int_t *lwork,
              armpl_int_t *info);
```

Parameters

M Input parameter.

M is INTEGER

The number of rows of the matrix A. M >= 0.

N Input parameter.

N is INTEGER

The number of columns of the matrix A. M >= N >= 0.

MB Input parameter.

MB is INTEGER

The row block size to be used in the blocked QR. MB > N.

NB Input parameter.

NB is INTEGER

The column block size to be used in the blocked QR. N >= NB >= 1.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the N-by-N upper triangular matrix R; the elements below the diagonal represent Q by the columns of blocked V (see Further Details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, M).

T Output parameter.

T is COMPLEX

T is an array,. dimension (LDT, N * Number_of_row_blocks) where Number_of_row_blocks = CEIL((M-N)/(MB-N)) The blocked upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks. See Further Details below.

LDT Input parameter.

LDT is INTEGER

The leading dimension of the array T. LDT >= NB.

WORK Output parameter.

(workspace) COMPLEX

(workspace) is an array, dimension (MAX(1, LWORK)) .

LWORK Input parameter.

The dimension of the array WORK. LWORK >= NB*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dlatsqr*, *slatsqr* and *zlatsqr*.

4.17.149 clauu2

clauu2 computes the product U * U^H or L^H * L, where the triangular factor U or L is stored in the upper or lower triangular part of the array A.

If UPLO = 'U' or 'u' then the upper triangle of the result is stored, overwriting the factor U in A. If UPLO = 'L' or 'l' then the lower triangle of the result is stored, overwriting the factor L in A.

This is the unblocked form of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine clauu2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void clauu2_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the triangular factor stored in the array A is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the triangular factor U or L. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the triangular factor U or L. On exit, if UPLO = 'U', the upper triangle of A is overwritten with the upper triangle of the product U * U^H ; if UPLO = 'L', the lower triangle of A is overwritten with the lower triangle of the product L^H * L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dlauu2*, *slauu2* and *zlauu2*.

4.17.150 clauum

clauum computes the product U * U^H or L^H * L, where the triangular factor U or L is stored in the upper or lower triangular part of the array A.

If UPLO = 'U' or 'u' then the upper triangle of the result is stored, overwriting the factor U in A. If UPLO = 'L' or 'l' then the lower triangle of the result is stored, overwriting the factor L in A.

This is the blocked form of the algorithm, calling Level 3 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine clauum(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void clauum_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the triangular factor stored in the array A is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the triangular factor U or L. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the triangular factor U or L. On exit, if UPLO = 'U', the upper triangle of A is overwritten with the upper triangle of the product U * U^H ; if UPLO = 'L', the lower triangle of A is overwritten with the lower triangle of the product L^H * L.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dlauum*, *slauum* and *zlauum*. It also exists with a native C interface as *LAPACKE_clauum*.

4.17.151 cpbtf2

cpbtf2 computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

```
 A = U**H * U ,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix, U^H is the conjugate transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpbtf2(UPLO, N, KD, AB, LDAB, INFO)
```

C specification:

```
#include "armpl.h"

void cpbtf2_(const char *uplo, const armpl_int_t *n, const armpl_int_t *kd,
             armpl_singlecomplex_t *ab, const armpl_int_t *ldab,
             armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

KD Input parameter.

KD is INTEGER

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB Input and output parameter.

AB is COMPLEX

AB is an array, dimension (LDAB, N). On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H of the band matrix A, in the same storage format as A.

LDAB Input parameter.

LDAB is INTEGER

The leading dimension of the array AB. LDAB >= KD+1.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *dpbtf2*, *spbtf2* and *zpbtf2*.

4.17.152 cpotf2

cpotf2 computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

```
 A = U**H * U ,  if UPLO = 'U', or
A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpotf2(UPLO, N, A, LDA, INFO)
```

C specification:

```
#include "armpl.h"

void cpotf2_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U^H *U or A = L*L^H .

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

Related Information

For this routine in other precisions, please see *dpotf2*, *spotf2* and *zpotf2*.

4.17.153 cpstf2

cpstf2 computes the Cholesky factorization with complete pivoting of a complex Hermitian positive semidefinite matrix A.

The factorization has the form

```
 P**T * A * P = U**H * U ,  if UPLO = 'U',
P**T * A * P = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector PIV.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine cpstf2(UPLO, N, A, LDA, PIV, RANK, TOL, WORK, INFO)
```

C specification:

```
#include "armpl.h"

void cpstf2_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *piv, armpl_int_t *rank,
             const float *tol, float *work, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization as above.

PIV Output parameter.

PIV is INTEGER array, dimension (N)

PIV is such that the nonzero entries are P(PIV(K), K) = 1.

RANK Output parameter.

RANK is INTEGER

The rank of A given by the number of steps the algorithm completed.

TOL Input parameter.

TOL is REAL

User defined tolerance. If TOL < 0, then N*U*MAX(A(K,K)) will be used. The algorithm terminates at the (K-1)st step if the pivot <= TOL.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

WORK Output parameter.

WORK is REAL

WORK is an array, dimension (2*N). Work space.

INFO Output parameter.

INFO is INTEGER

< 0: If INFO = -K, the K-th argument had an illegal value, = 0: algorithm completed successfully, and > 0: the matrix A is either rank deficient with computed rank as returned in RANK, or is not positive semidefinite. See Section 7 of LAPACK Working Note #161 for further information.

Related Information

For this routine in other precisions, please see *dpstf2*, *spstf2* and *zpstf2*.

4.17.154 cptts2

cptts2 solves a tridiagonal system of the form

```
A * X = B
```

using the factorization A = U^H *D*U or A = L*D*L^H computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

Syntax

Fortran specification:

```
use armpl_library

subroutine cptts2(IUPLO, N, NRHS, D, E, B, LDB)
```

C specification:

```
#include "armpl.h"

void cptts2_(const armpl_int_t *iuplo, const armpl_int_t *n,
             const armpl_int_t *nrhs, const float *d,
             const armpl_singlecomplex_t *e, armpl_singlecomplex_t *b,
             const armpl_int_t *ldb);
```

Parameters

IUPLO Input parameter.

IUPLO is INTEGER

Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 1: A = U^H *D*U, E is the superdiagonal of U = 0: A = L*D*L^H , E is the subdiagonal of L

N Input parameter.

N is INTEGER

The order of the tridiagonal matrix A. N >= 0.

NRHS Input parameter.

NRHS is INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D Input parameter.

D is REAL

D is an array, dimension (N). The n diagonal elements of the diagonal matrix D from the factorization A = U^H *D*U or A = L*D*L^H .

E Input parameter.

E is COMPLEX

E is an array, dimension (N-1). If IUPLO = 1, the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization A = U^H *D*U. If IUPLO = 0, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization A = L*D*L^H .

B Input and output parameter.

B is COMPLEX

B is an array, dimension (LDB, NRHS). On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB Input parameter.

LDB is INTEGER

The leading dimension of the array B. LDB >= max(1, N).

Related Information

For this routine in other precisions, please see *dptts2*, *sptts2* and *zptts2*.

4.17.155 csrscl

csrscl multiplies an n-element complex vector x by the real scalar 1/a. This is done without overflow or underflow as long as the final result x/a does not overflow or underflow.

Syntax

Fortran specification:

```
use armpl_library

subroutine csrscl(N, SA, SX, INCX)
```

C specification:

```
#include "armpl.h"

void csrscl_(const armpl_int_t *n, const float *sa, armpl_singlecomplex_t *sx,
             const armpl_int_t *incx);
```

Parameters

N Input parameter.

N is INTEGER

The number of components of the vector x.

SA Input parameter.

SA is REAL

The scalar a which is used to divide each component of x. SA must be >= 0, or the subroutine will divide by zero.

SX Input and output parameter.

SX is COMPLEX

SX is an array, dimension. (1+(N-1)*abs(INCX)) The n-element vector x.

INCX Input parameter.

INCX is INTEGER

The increment between successive values of the vector SX. > 0: SX(1) = X(1) and SX(1+(i-1)*INCX) = x(i), 1< i<= n

Related Information

4.17.156 csyconv

csyconv convert A given by TRF into L and D and vice-versa. Get Non-diag elements of D (returned in workspace) and apply or reverse permutation done in TRF.

Syntax

Fortran specification:

```
use armpl_library

subroutine csyconv(UPLO, WAY, N, A, LDA, IPIV, E, INFO)
```

C specification:

```
#include "armpl.h"

void csyconv_(const char *uplo, const char *way, const armpl_int_t *n,
              armpl_singlecomplex_t *a, const armpl_int_t *lda,
              const armpl_int_t *ipiv, armpl_singlecomplex_t *e,
              armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

WAY Input parameter.

WAY is CHARACTER*1

= 'C': Convert = 'R': Revert

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Input parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D as determined by CSYTRF.

E Output parameter.

E is COMPLEX

E is an array, dimension (N). E stores the supdiagonal/subdiagonal of the symmetric 1-by-1 or 2-by-2 block diagonal matrix D in LDLT.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

Related Information

For this routine in other precisions, please see *dsyconv*, *ssyconv* and *zsyconv*. It also exists with a native C interface as *LAPACKE_csyconv*.

4.17.157 csyswapr

CSYSWAPR applies an elementary permutation on the rows and the columns of a symmetric matrix.

Syntax

Fortran specification:

```
use armpl_library

subroutine csyswapr(UPLO, N, A, LDA, I1, I2)
```

C specification:

```
#include "armpl.h"

void csyswapr_(const char *uplo, const armpl_int_t *n,
               armpl_singlecomplex_t *a, const armpl_int_t *lda,
               const armpl_int_t *i1, const armpl_int_t *i2, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix. = 'U': Upper triangular, form is A = U*D*U^T ; = 'L': Lower triangular, form is A = L*D*L^T .

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the NB diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

I1 Input parameter.

I1 is INTEGER

Index of the first row to swap

I2 Input parameter.

I2 is INTEGER

Index of the second row to swap

Related Information

For this routine in other precisions, please see *dsyswapr*, *ssyswapr* and *zsyswapr*. It also exists with a native C interface as *LAPACKE_csyswapr*.

4.17.158 csytf2

csytf2 computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^T is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytf2(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void csytf2_(const char *uplo, const armpl_int_t *n, armpl_singlecomplex_t *a,
             const armpl_int_t *lda, armpl_int_t *ipiv, armpl_int_t *info,
             ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO Output parameter.

INFO is INTEGER

= 0: successful exit < 0: if INFO = -k, the k-th argument had an illegal value > 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Related Information

For this routine in other precisions, please see *dsytf2*, *ssytf2* and *zsytf2*.

4.17.159 csytf2_rook

CSYTF2_ROOK computes the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^T is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

Syntax

Fortran specification:

```
use armpl_library

subroutine csytf2_rook(UPLO, N, A, LDA, IPIV, INFO)
```

C specification:

```
#include "armpl.h"

void csytf2_rook_(const char *uplo, const armpl_int_t *n,
                  armpl_singlecomplex_t *a, const armpl_int_t *lda,
                  armpl_int_t *ipiv, armpl_int_t *info, ... );
```

Parameters

UPLO Input parameter.

UPLO is CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular

N Input parameter.

N is INTEGER

The order of the matrix A. N >= 0.

A Input and output parameter.

A is COMPLEX

A is an array, dimension (LDA, N). On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA Input parameter.

LDA is INTEGER

The leading dimension of the array A. LDA >= max(1, N).

IPIV Output parameter.

IPIV is INTEGER array, dimension (N)

Details of the interchanges and the block structure of D.

If UPLO = 'U': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.

If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and columns k and -IPIV(k) were interchanged and rows and columns k-1 and -IPIV(k-1) were inerchaged, D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

If UPLO = 'L': If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block.
